Chicago

Until the 1830s a minor trading post at a swampy river mouth near the southwestern tip of Lake Michigan, Chicago made use of its strategic location as the interior land and water hub of the expanding United States to become the centre of one of the world's richest industrial and commercial complexes. It is the third most populous city and metropolitan area in the United States. Chicago's achievements are distinctly characteristic of the country as a whole, and its problems are the problems of the modern United States; in a sense it may be—as a series of observers has called it—the typical American city.

The relations between this youthful city and its rural environment are also noteworthy. Throughout its history, Chicago and the surrounding counties of what became its metropolitan area, now containing about two-thirds of the population of Illinois, have existed as almost a separate entity—politically, socially, and spiritually—from largely rural "Downstate" Illinois. The attitudes and lives of the early settlers in and around the burgeoning city, mainly from the Northeastern states or from Europe, were in contrast to those of Downstaters, many of whom came from Appalachian or Southern states. While Chicago was, for example, a major supplier of goods and manpower to the Union during the Civil War, in southern Illinois there was an unsuccessful but strong movement toward secession and alliance with the Confederacy. This alienation continues to plague the political and social life of both the city and the state.

This article is divided into the following sections:

Physical and human geography

THE CHARACTER OF CHICAGO

A by-product of Chicago's growth on the raw frontier of U.S. industry was its reputation as a city in which "anything goes," a city whose name became an international byword for underworld violence during and after the Prohibition era of the 1920s and early 1930s. This sort of mayhem has long been overshadowed in Chicago as elsewhere in the United States by the random violence of daily urban life. Municipal corruption, another commodity on which Chicago was long thought to have cornered the market, is likewise not in fact a local monopoly, though Chicagoans perhaps have a higher tolerance for human frailty among politicians—politics in Chicago being to an extent an expensive form of public entertainment—than do the citizens of other municipalities. As theologian Martin Marty of the University of Chicago observed, after revelations that politicians of both parties had profited enormously from ownership of racetrack stocks, "Someplace else it might be shocking. . . . Children grow up here knowing things are rigged and fixed."

Urban vistas

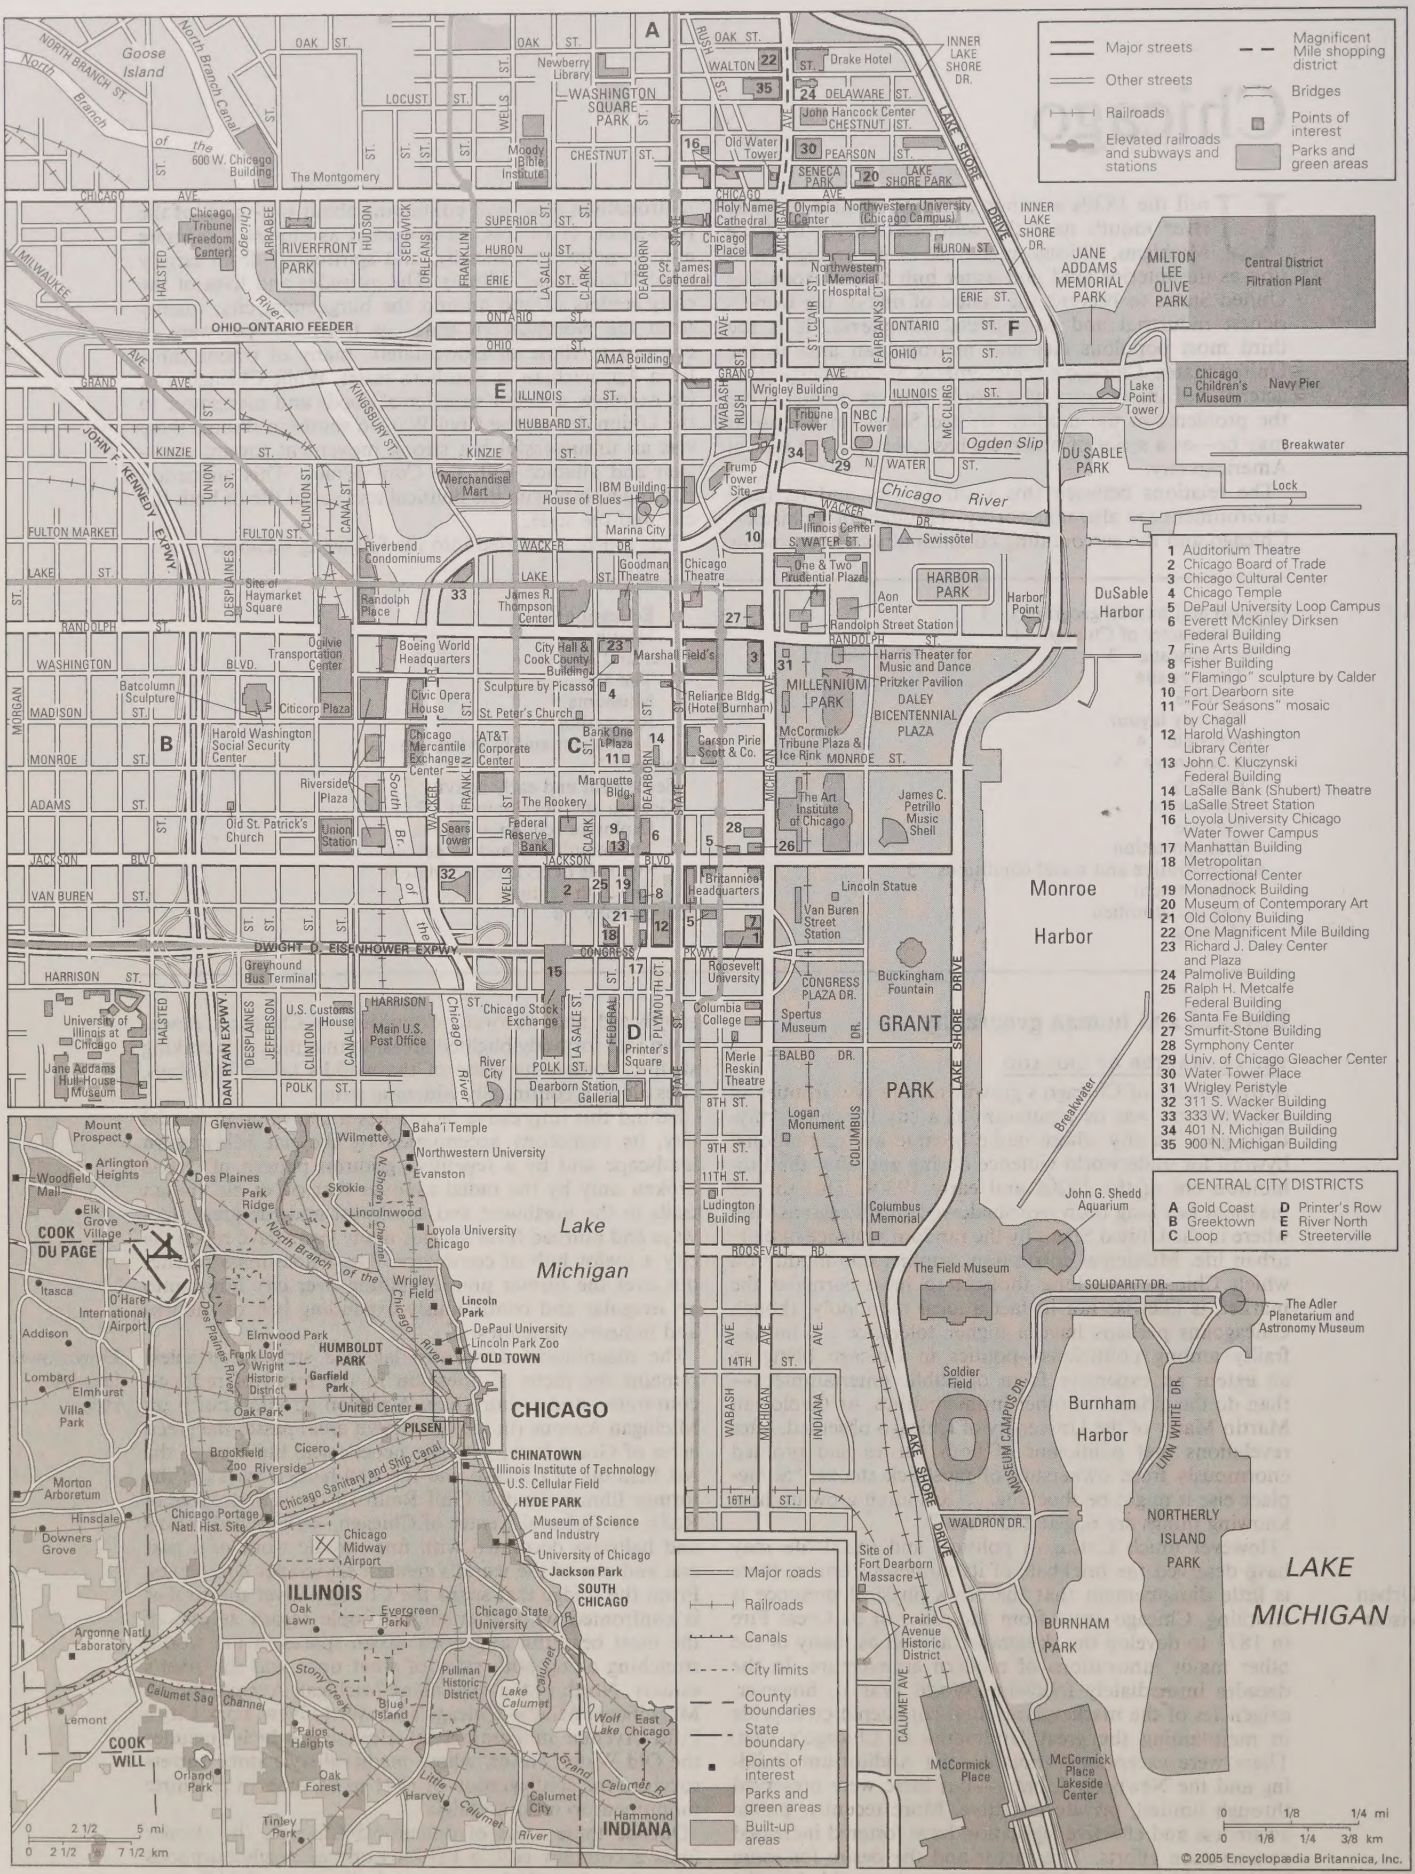
However much Chicago's political and social life may have deserved the brickbats of its numerous critics, there is little disagreement that the city's physical presence is stunning. Chicago arose from the ashes of its Great Fire in 1871 to develop the skyscraper as well as many of the other major innovations of modern architecture. In the decades immediately following World War II, however, exigencies of the marketplace often conquered civic pride in maintaining the great landmarks of Chicago's past. There were exceptions—notably, the Auditorium Building and the Newberry Library—but these were preserved through limited, private initiative. More recently, public awareness and effective legislation have fostered increased conservation efforts. This factor and the desire for more land on which to build new structures have aided in the southward and westward expansion of Chicago's downtown into formerly blighted areas, so that the city's striking skyline, containing some of the world's tallest buildings, rises along a continually widening strip.

Behind this impressive facade lies a sprawling industrial city, its monotony accentuated by the flat Midwestern landscape and by a repetitive gridiron pattern of streets broken only by the radial avenues that cover old Indian trails to the northwest and southwest and the great freeways and railroad lines that for many years have made the city a major hub of commerce. The whole mass reaches out over the former prairie, spilling over city limits into an irregular and continuously expanding belt of suburbs and industrial satellites.

Downtown lakeside strip

The magnificent downtown lakeside strip nevertheless remains the focus of attention in the mind of resident, commuter, and visitor alike. A person strolling north on Michigan Avenue (in the downtown area) passes the green acres of Grant Park, with the neoclassical building of the Art Institute of Chicago and the well-hidden tracks of the former Illinois Central Gulf Railroad (now Metropolitan Rail); the Cultural Center of Chicago, with arched rooms and hallways decorated with fine mosaic work of a past era; and one of the world's greatest skyscraper complexes. From the bridge that spans the Chicago River the stroller is confronted with what many people regard as one of the most beautiful and open urban spaces in the world, stretching along both sides of what once was the river's estuary. North of the river along Michigan Avenue is "the Magnificent Mile"—Chicago's answer to New York City's Fifth Avenue in commercial elegance—which includes the Old Water Tower, whose medieval-style stone turrets survived the conflagration of 1871 to become an eccentric monument to civic nostalgia.

Outside these areas of downtown Chicago, the stroller finds a complex city, a kaleidoscope of neighbourhoods mirroring the ethnic and racial diversity of U.S. life.



Central Chicago and (inset) its metropolitan area.

Chicago remains essentially the "blue-collar" city characterized by the poet Carl Sandburg as the "city of big shoulders," heavily populated by the descendants of labourers from the streets and soils of 19th-century Europe and of former slaves from the Deep South. The latest influx—that of Spanish-speaking residents and of immigrants from Southeast Asia and eastern Europe—has added further to the complexity.

Civic disasters of the 19th and 20th centuries

Chicago's widely scattered ethnic neighbourhoods and its suburbs have retained memories of a long series of disasters, running from the time of the Great Chicago Fire itself. In the 19th century these included the police assault on strikers that left several wounded or killed, the apparently retaliatory bomb throwing (attributed to anarchists) that killed seven policemen, and the ensuing reaction against German-American leaders, all associated with the Haymarket Square Riot. Many other bitter, often fatal, labour disputes occurred in the steel, railroad, packinghouse, and other industries. These were followed by the catastrophic Iroquois Theater Fire; the sinking of the cruise ship *Eastland* in the Chicago River, drowning more than 800 people; the reputation of gangsterism and intermittent mayhem evoked by mention of Al Capone, John Dillinger, and the St. Valentine's Day Massacre in the early 20th century; the televised violence between police and protesters during the 1968 Democratic convention; and a continuing succession of major and minor municipal corruptions. At the same time, "the windy city"—a meteorologically correct nickname nevertheless derived from the inflated claims of the early municipal "boosters"—has laid claim to a distinguished list of citizens who have significantly enriched the intellectual, artistic, and social life of the United States.

It has been said that Chicago's intelligentsia is hindered by a "second city" mentality and an accompanying tendency toward self-disparagement. That may indeed be true, but such a designation is also less likely to inhibit risk-taking experimentation, as evidenced by Chicago's artistic achievements. The city has once again regained its reputation as a major theatre centre, and its contemporary styles of architecture are imaginative and sometimes controversial. This willingness to try something new—epitomized by a huge abstract Picasso sculpture, a gift to the city from the artist himself—continues to entertain Chicagoans and the city's millions of tourists and conventioneers. (R.Do./Ed.)

THE LANDSCAPE

The city site. The city of Chicago proper occupies 228 square miles (591 square kilometres). The Chicago Standard Metropolitan Statistical Area (SMSA) consists of Cook County and five surrounding Illinois counties, and the Chicago–Gary–Kenosha Standard Consolidated Statistical Area (SCSA) is made up of nine counties—two of them in northwestern Indiana and one in southeastern Wisconsin.

Chicago's site is generally level, rising from the shore of Lake Michigan, averaging 579 feet (176 metres) above sea level, to slightly more than 600 feet in outlying portions of the city. Most of Chicago is built on a plain, the remnant of postglacial Lake Chicago, formed when the retreating continental glacier blocked normal northeastward drainage through the St. Lawrence Valley about 10,000 to 12,000 years ago. Outlying portions of the metropolitan area, formed from material deposited by the glaciers, rise to more than 700 feet.

Flow of the Chicago River

The narrow Chicago River extends 1 mile (1.6 kilometres) inland from Lake Michigan, where it splits, dividing the city into North, West, and South sides. Its original flow was into Lake Michigan, but completion of the Chicago Sanitary and Ship Canal in 1900 reversed it, since the bottom of the canal is below the surface of Lake Michigan. Near the southeastern corner of the city, the flow of the Calumet River was reversed by the Calumet Sag Channel, completed in 1922 and enlarged from 1955 to 1972 as a modern barge route. The two waterways join southwest of the city and receive treated sewage effluent from three plants of the Metropolitan Sanitary District of Greater Chicago, as well as wastes from industrial plants and outlying areas. During high runoff the rivers occasionally revert to their original lakeward drainage, and some flooding occurs in low-lying areas.

Climate. The climate is subject to rapid changes of weather as successions of air masses pass generally from west to east. Lake Michigan tends to mitigate extremes, with lower air temperatures in summer and higher in winter generally occurring close to the lake.

January temperatures average about 25° F (−4° C) and July 75° F (24° C). Annual precipitation averages about

The Sears Tower (centre) and other buildings of the western downtown area of Chicago, looking south from the north branch of the Chicago River.
Kanna Wang/PhotoScapes

33 inches (838 millimetres), and heavy snows occasionally disrupt local transportation.

The city layout. Chicago meets its suburbs in a ragged pattern of boundaries on three sides, while on the east the lakefront curves from northwest to southeast. The area centring on the forks of the river was platted on a grid-iron pattern in 1830 following specifications of the Northwest Ordinance of 1787. This plan was generally followed in the rest of the city, though it was broken often by radial avenues (some along old trails leading to the river mouth) and other features, such as the Burnham Plan of Chicago (1909), rail lines and yards, industrial sites, and parks.

Downtown Chicago has been known as the "Loop" since 1897, when several elevated lines were joined into an overhead loop of tracks encircling an area that covers some 35 blocks and receiving feeder lines from north, west, and south. The building boom that began in the mid-1950s extended the highly concentrated business district westward from the Loop and, from the 1970s, into the Near West Side beyond the river's south branch. Many new skyscrapers have radically altered the city's skyline. North Michigan Avenue, initially developed following completion of the Michigan Avenue Bridge in 1920, and adjacent Near North sites have experienced much high-rise commercial and residential building since the 1960s, the most notable being the 100-story John Hancock Center, the 74-story Water Tower Place, and the 66-story 900 North Michigan Building. All are multipurpose skyscrapers containing shopping facilities, restaurants, offices, and apartments. Other major downtown office buildings completed since 1970 include the 110-story, 1,450-foot Sears Tower—one of the world's tallest buildings—just west of the Loop, the 83-story Aon Center (formerly Amoco Building) east of the Loop, and the 65-story 311 South Wacker Building just south of Sears Tower. Also notable is the complex of office and apartment buildings and hotels on either side of the Chicago River east of Michigan Avenue. In addition, there has been considerable residential development south, west, and northwest of downtown in formerly run-down areas.

Grant Park in downtown Chicago, Lincoln Park on the North Side, and Jackson and Burnham parks on the South Side stretch for miles along the lakefront. Millennium Park (opened 2004), adjacent to Grant Park downtown, was built over rail lines and parking facilities. The city has an extensive park system inland as well.

Industrial areas

The city's main industrial areas developed along the two branches of the Chicago River and in the Calumet region to the southeast, later expanding along railroad lines and in satellite cities, such as Waukegan, Aurora, Joliet, and Chicago Heights in Illinois and the Gary–Hammond–East Chicago complex in northwestern Indiana. Oil refineries and iron and steel, chemical, and fabricating plants were built in south Chicago, along and near the Calumet River and along the lakefront in adjacent Indiana. The first steel plant in the area was established at the entrance of the Calumet River in 1880, followed by additional large plants nearby and at Indiana Harbor. Gary was founded as a major steel-producing centre in 1906, and large steel plants were built at Burns Harbor, east of Gary, in the 1960s. By the early 21st century, however, many of these plants had closed or been converted to other uses. Meanwhile, the principal terminal of the Great Lakes–St. Lawrence Seaway overseas shipping route was developed after 1956 in Lake Calumet, six miles up the Calumet River from Lake Michigan, supplemented later by the Iroquois Landing terminal at the entrance of the Calumet River.

THE PEOPLE

The proportion of foreign-born population of Chicago and the metropolitan area has fluctuated with trends in immigration. For example, according to the 1970 census, most of the foreign-born were from central and eastern European countries. By the 2000 census, however, there had been large increases in the numbers of Spanish-speaking people of Latin-American origin and of people of Asian origin, and the proportion of immigrants from Europe had declined.

Although there were a few blacks in Chicago from the earliest period of the city's growth, immigration was accelerated during and after World War I. The African-American population increased from 233,000 in 1930 to more than 1,000,000 in 2000, when it represented greater than one-third of the city's population.

North of the Loop, the Lake Shore Drive mansions largely have been replaced by equally luxurious high-rise apartment buildings that extend the lakefront Gold Coast almost to the city's northern border. Inland from this strip lies a narrow band of shorter apartment buildings and older homes occupied largely by single persons and families of professional people.

The area adjacent to the University of Chicago on the South Side forms one of the city's major intellectual communities, though it sits amid one of the more blighted sections of the city. Other universities contributing to local social patterns are DePaul and Loyola on the North Side and the University of Illinois at Chicago, the construction of which in the 1960s uprooted much of the old Italian community southwest of downtown.

Ethnic communities

Many ethnic groups continue to form more or less homogeneous communities in various parts of the city. The Irish, long in control of the city's politics, are widespread, and a largely Irish region on the South Side spawned several mayors of Chicago—all Democrats. Chicago's Polish community, the largest in the country, remains heavily concentrated on the Near Northwest and Northwest sides. Swedish and German neighbourhoods reach through the North and Northwest sides, Czechs and Slovaks have spread into the southwestern suburbs, while the traditional Greek neighbourhood is just west of the Loop.

Heavily Jewish populations are characteristic of the Far North and the adjoining suburbs of Lincolnwood and Skokie. The Chinese community is concentrated on the South Side, and Japanese, Korean, and South Asian communities are found mainly on the North Side.

Many of these ethnic communities have lost most of their distinctive character as the newer generations have become homogenized into U.S. life. Foreign tongues remain in evidence, however, together with storefront restaurants and traditional shops that add Old World flavour to the Chicago neighbourhoods.

The original main axis of black settlement was along mass-transit lines, especially through the South Side, where access to industrial employment was favourable. During and after World War II, the South Side "black belt" expanded within the city and into adjacent suburbs, while additional areas of the West Side, once heavily Jewish, and parts of the Near North were occupied by blacks. In both the city and suburbs, most black areas previously had been occupied by first or second generations of foreign origin who either left already deteriorating neighbourhoods or fled a growing influx of blacks. Middle-class and affluent black neighbourhoods developed in areas of social and economic stability.

Residential suburbs first grew up along the principal rail lines, but since World War II much suburban development has taken place, commonly at lower densities, in the areas between the earlier radial axes. A suburban real-estate boom in 1869 created new communities that were able to absorb many of the people burned out by the Great Fire. Among these was Riverside, west of the city, laid out in irregular streets and with exemplary planning, which has enabled the community to retain its character. To the north of the city, such lakeside communities as Evanston, Winnetka, and Lake Forest began a steady growth that made the North Shore the most prestigious of suburban areas. Meanwhile, western suburbs like Naperville and Bolingbrook grew rapidly after 1970.

Among developments that encouraged residential deconcentration after World War II were new express highways; expansion of industries outside the city; huge regional shopping centres, the sales of which rival those downtown; O'Hare International Airport (later annexed to the city) and its surrounding complex of hotels, motels, shopping centres, office buildings, and industrial districts; nuclear-research facilities, including the Argonne National Laboratory and the Fermi National Accelerator Laboratory (Fer-

milab) near Batavia; and many communities and "new towns." The first of these, Park Forest, was begun in 1947 about 30 miles south of the city's centre.

THE ECONOMY

Industry. Chicago and its metropolitan area have remained the most important focus of economic activity in interior North America. Its economic base, with a balance between industry and commerce, is highly diversified. Nevertheless, the city has suffered, along with many other metropolitan areas of the Northeast and Middle West, from the shift in population and economic activity to the "Sun Belt" of the South and West and from foreign industrial competition.

Manufacturing provides about one-fourth of the region's employment; leading categories are steel, metal products, food products and confections, metal furniture, chemicals, soap, paint, machine tools, communications equipment and electronic goods, railroad equipment, surgical appliances, and scientific instruments.

The blue-collar and white-collar economy

Chicago's steel supply and its strategic situation as the major transportation node of the continent has enabled it to assume leadership in the manufacture of a wide variety of machinery and fabricated metal products, ranging from diesel-electric locomotives to printing presses, material-handling equipment, and earth-moving and agricultural machinery.

A wide variety of chemicals and allied products serve both industrial and consumer markets. Closely associated are several large petroleum refineries, principally in the Calumet area and northwestern Indiana.

Chicago's printing establishments include several of the world's largest. Many nationally distributed magazines and mail-order catalogs, as well as a substantial proportion of the country's telephone directories, are produced in these plants. Enormous quantities of paper, much of it from Canada, reach Chicago by water. The city ranks second to New York City in the white-collar aspects of publishing, though it tends to specialize in such areas as educational materials, encyclopaedias, and professional and trade publications. It is also the home office of several major advertising and public-relations firms.

Situated between the agricultural Midwest and the urban-industrial Northeast, Chicago remains a leader in food processing, although by the early 1970s the Union Stock Yards had terminated all meat-processing activities.

Commerce. Commercial activities of nationwide importance include trading in commodities futures on the Chicago Board of Trade and the Chicago Mercantile Exchange and associated brokerage offices and related establishments.

Convention facilities

Chicago has more trade shows, conventions, and corporate meetings than any other U.S. city. The Merchandise Mart, with most of its 4,000,000 square feet of floor area devoted to wholesaling activities, was for many years the world's largest commercial building. Other facilities, such as the Apparel Center of Chicago, serve specialized wholesaling industries. Convention and trade-show facilities include concentrations of hotels and motels, notably in the downtown area and in the vicinity of O'Hare Airport, together with the convention hall at McCormick Place-on-the-Lake, opened in 1971 to replace a smaller facility destroyed by fire.

Finance. Chicago is the site of a Federal Reserve Bank, established in 1914. Most large banks are in the Loop area, and, because Illinois prohibits branch banking, the outlying neighbourhoods and suburbs are served by limited-service facilities, smaller banks, currency exchanges, and savings-and-loan associations.

The city is also the site of the Midwest Stock Exchange and offices of most major brokerage houses. Many insurance companies are in the city or suburbs, including the nation's two largest automobile insurers.

Transportation. In addition to Chicago's standing as a major inland port and railroad hub of the nation, O'Hare International Airport is the world's busiest. By the late 1960s the older, smaller Midway Airport had been pressed into service again to relieve congestion. Metropolitan Chicago's dominance as the most important railroad freight centre in North America has continued, although railroad mergers, the rise of intermodal transportation, and the deregulation of many aspects of the transportation industry have presented new challenges to the region's supremacy. Chicago lost many intercity passenger trains before and after the advent of the quasi-public Amtrak system in 1971. Its several commuter lines serving suburbs to the north and west are widely regarded, however, as the finest in the nation in terms of comfort, punctuality, and overall service. The Regional Transportation Authority (RTA), established in 1973, is responsible for most suburban railroad and bus service, as well as for the rapid-transit and bus services of the Chicago Transit Authority (CTA) within the city and in some nearby suburbs. Both the CTA and RTA have become increasingly debt ridden in spite of having one of the nation's highest fare structures.

The expressway system built after World War II has become congested, as has Lake Shore Drive, which reaches nearly from the northern to southern city limits and provides scenic views of both the lake and the city skyline.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. The spiritual chasm between Chicago and the rest of Illinois is perhaps widest in the political and social spheres and deepest in the struggles between city hall and the state government. Chicago Democrats and Downstate Republicans have found few issues over the years that could be debated on a basis other than that of partisan politics. Until the one-person, one-vote reapportionment of the legislature in the 1960s, the whip was usually in the hands of the sparsely populated Downstate counties. In addition, the growth in population and wealth of the suburbs after World War II has created a second front on which Chicago, like most large U.S. cities, is forced to wage a defensive campaign against a growing drain on its human and financial resources.

Routine operation and long-term planning in the Chicago SMSA are complicated by the continuous proliferation of overlapping administrative and taxing units of government. In addition to the almost 300 incorporated municipalities and the unincorporated areas under administration of the counties, the SMSA has more than 500 special districts—elementary and high school and community college, park, forest preserve, drainage, sanitary, and the like—established to circumvent state-imposed limitations on borrowing. Such authorities as public housing, ports, transit, and highways operate without taxing power. State and federal funds and, when appropriate, user charges supplement local outlays.

Overlap of administrative institutions

The Northeastern Illinois Planning Commission, created by the state in 1957, coordinates planning, especially among suburban governments. All projects involving federal aid must conform to the commission's comprehensive plan, adopted in 1968 and periodically reviewed, for the six counties of the SMSA.

Chicago's government long has been handicapped by an unwieldy structure not adapted to efficient administration of a modern urban region. Power is concentrated in a mayor who presides over the City Council of aldermen representing the city's 50 wards. The mayor, with City Council approval, also appoints members of the Board of Education, Park District, Housing Authority, and other special-purpose boards and commissions.

This formal scattering of power long has nurtured an informal but highly structured and disciplined political machine in Chicago that was brought to its peak of efficiency during the administration of Mayor Richard J. Daley, widely regarded as "the last of the big-city bosses" well before his reelection to a sixth four-year term in 1975. As chairman of the Cook County Democratic Party, he wielded great power beyond the city limits and was recognized as the predominant voice in the statewide party and a major power in the national Democratic Party. A deeply entrenched patronage system in all areas of government was moved into its highest gears for elections, and accusations and denials of voting irregularities were a constant feature of Chicago's political life. Opponents often charged that city building inspectors and other officials employed statutory sanctions to enforce party loyalty or punish dis-

Patronage and the political machine

affection and that the City Council, in spite of a scattering of liberal independent and Republican aldermen, served as little more than a rubber stamp for mayoral programs.

The foundations of the "Organization," as it is called by its adherents, were laid during the brief term (1931–33) of Anton Cermak, a Bohemian immigrant who quickly mastered the politics of Chicago's ethnic ghettos, opposed the Prohibition that was unpopular with immigrant workers, and carefully balanced Democratic slates and platforms among the many ethnic, labour, and business interests. Innovative programs for municipal conservation and rebuilding renewal that were begun during the reformist administration of Martin Kennelly (1947–55) were moved ahead rapidly only after Daley's accession in 1955. For more than 20 years an unofficial alliance of labour unions, civic and business leaders (often suburbanites), and party faithful from the precinct level upward, with heavy voting support from the blue-collar and ethnic communities, maintained the Organization's hold on Chicago's political life. Daley was the catalyst of the Organization's unity, and his death in 1976 marked the beginning of the end of its total dominance of city politics. In 1979 the city elected its first woman mayor, Jane M. Byrne, and by the early 1980s there were many "independent" (*i.e.,* non-Organization) Democratic aldermen in the City Council. In 1983 Chicago elected its first African American mayor, Harold Washington; he died in office in 1987. Richard M. Daley, son of the elder Daley, was elected mayor in 1989.

The social milieu. The tremendous growth and spread of its black population and the concomitant flight of middle- and upper-class whites and of commerce to the suburbs probably was the most dominant feature of Chicago's social picture after World War II. The city's few black aldermen tended to align themselves with the political machine and bring it the votes of the black community. The growing Spanish-speaking community, without political representation, intensified the situation.

Black opposition began to grow and become organized in the 1960s. One of the earliest groups to form was Operation Breadbasket—an economic activity of the Southern Christian Leadership Conference founded by Martin Luther King, Jr.—which mounted campaigns, often in conjunction with businesses and citizen groups controlled by whites, to achieve greater economic and political power for the black community. Its successor, Operation PUSH (now the Rainbow/PUSH Coalition), and other organizations continued to mobilize blacks who were increasingly frustrated with Mayor Daley and the Organization. By the early 1980s massive voter-registration drives had given the black community a powerful constituency that was able to elect Washington and about one-third of the aldermen in the City Council, many of whom were independent Democrats.

Housing. A fundamental clash of values became apparent in the 1960s when Daley, in rebutting a charge that Chicago was the most segregated city in the country, declared that the city had no ghettos. Numerous restrictive real-estate practices, however, long had been in effect in Chicago; these were tightened further after a six-day race riot in 1919 that killed at least 33 persons. Scores of incidents occurred in following years. The inevitable outward explosion of the black community after World War II was abetted by unscrupulous real-estate operators but opposed by "block organizations" and other militant white-citizen groups, especially on the South and West sides.

By 1980 the Chicago Housing Authority had built about 45,000 units of low-rent housing, mainly as massive high-rise apartment projects that, in the view of many persons, tended to intensify the crime, isolation, and other evidences of life in the slums they were intended to replace and to epitomize the worst aspects of racial and socioeconomic segregation. Private institutions, such as the Illinois Institute of Technology on the South Side, had better fortune with privately financed middle-income housing projects. A combination of redevelopment, conservation, and social programs in the area centred on the University of Chicago became a prototype for treatment of changing urban communities. Redevelopment plans for several of the city's public housing projects got under way in the late 1990s; changes included demolishing many of the high-rise apartment buildings and constructing less densely populated low-rise structures.

In 1971 the city's participation in the federally funded Model Cities program was jeopardized by the administration's reluctance to locate low-rent public housing in predominantly white neighbourhoods. At the same time, a number of the suburbs, many of which had fair-housing laws, resisted such housing and were largely unreceptive to pleas for housing aid from the city.

Education. The racial patterns of Chicago's public schools reflect neighbourhood residential patterns, with few attempts at integration and a relatively low standing in comparison with nationwide achievement standards. Both the public schools and the Roman Catholic parochial schools, which make up the nation's largest private-school system, have teetered on the brink of financial calamity and provoked intense city–state political feuds.

Higher Education

In higher education the University of Chicago long has been among the nation's most prestigious institutions. Both the Illinois Institute of Technology and Northwestern University, the latter with campuses in Evanston and Chicago, have national reputations, while Loyola and DePaul universities are major Roman Catholic institutions. Roosevelt University, in downtown Chicago, founded in 1945, offers a diverse curriculum especially geared toward an urban student body. The University of Illinois at Chicago complements the main campus in Champaign–Urbana.

Health. Chicago is among the major medical- and dental-training centres in the nation, and its hospitals and research facilities are of high quality. As in many cities, service to the poor remains deficient, heavily encumbered by partisan political controversy. Publicly supported Cook County Hospital, one of the nation's largest, has often found itself embroiled in political and financial crises that tend to affect its services, while neighbourhood clinics in black and Spanish-speaking areas, staffed mainly by young doctors and medical students, have been in frequent conflict with the politically run Board of Health.

CULTURAL LIFE

The arts. Its reputation as a boisterous and crassly commercial city notwithstanding, Chicago has fostered a robust artistic life throughout most of its history. It was a major theatre centre during the late 19th and early 20th centuries, and, before the discovery of Hollywood in the early 20th century, it was the cradle of the infant U.S. motion-picture industry. During the 1950s the Second City troupe began a series of theatrical innovations that were to provide many new directions and talents to the entertainment world. The nationally recognized Goodman School of Drama, long affiliated with the Art Institute of Chicago, initiated a resident professional company in 1970 and became one of the eight colleges of DePaul University in 1978. Of the many other drama troupes, the best known is the Steppenwolf Theatre Company, which has staged numerous innovative and award-winning plays and produced such notable film and television actors as John Malkovich, Laurie Metcalf, Gary Sinise, and Joan Allen.

Theatre

The status of the Chicago Symphony Orchestra as one of the world's major musical ensembles was firmly established during the tenure of Sir Georg Solti as music director (1969–91); he was succeeded by Daniel Barenboim. Chicago opera revived when the Lyric Opera was founded in 1954 to provide Chicago with brief but regular seasons of opera of a high calibre. Chicago's place in literature was at its highest in the early decades of the 20th century, especially with the publication of *Poetry* magazine. Many Chicago writers have gained renown, but the city's peculiar literary genius has shown itself most prominently in the field of journalism—from bucolic Midwestern homily to stinging social and political commentary.

Architecture

Although Chicago and environs have incubated the most outstanding examples of modern domestic and commercial architecture, the city's record in preserving its landmarks has been a depressing one. The razing of Louis Sullivan's Stock Exchange Building in 1971 epitomized to conservationists and historians a callousness toward the city's aesthetic heritage that already had replaced nu-

merous architectural landmarks with more profitable but uninspired buildings. Considerable interest has developed, however, in preserving Chicago's older buildings of architectural value, and the results are evident in the rehabilitation of many structures. Others have been adapted to new and innovative uses, including Fulton House, a former warehouse converted to a luxury apartment building, and the buildings in Printing House Row.

Architecturally Chicago remains among the finest of the world's large cities, but its plan and skyline have been threatened by an increasing number of conventionalized structures indifferently adapted from the buildings of Ludwig Mies van der Rohe, an innovative genius who had renewed Chicago's architectural history in the years following World War II.

Cultural and scientific institutions

Museums. Its many and diversified collections of painting, sculpture, prints, photographs, and handicrafts rank the Art Institute of Chicago among the major museums of the world. In addition, its school makes it an important training centre for the fine arts. The Museum of Contemporary Art provides Chicagoans with a complementary point of view through its exhibitions of the leading edge of artistic endeavour. There are also several commercial galleries that sponsor exhibitions of works by artists with local as well as national and international reputations.

The exhibitions of the Museum of Science and Industry, housed in a huge remnant of the world's fair of 1893, are rivalled in the United States only by those of the Smithsonian Institution in Washington, D.C. The public displays and research activities of the Field Museum of Natural History place it among the leading scientific institutions of the world. Nearby are the John G. Shedd Aquarium and the Adler Planetarium.

Recreation. The city's extensive park system is supplemented by forest preserves located along the original city limits and in suburban areas of Cook County. Sandy beaches, in intermittent patches along Lake Michigan, provide summertime recreation.

Professional sports spark civic enthusiasm for the White Sox and Cubs in baseball, the Bears in football, the Black Hawks in hockey, and the Bulls in basketball. For Chicagoans and visitors alike, the many entertainments available in the Near North Side area of nightclubs and cabarets are a continuous attraction.

Journalism and broadcasting. Chicago has two metropolitan daily newspapers: the *Chicago Tribune* and the *Chicago Sun-Times*. The *Chicago Defender* is oriented primarily to the city's black population. There are many suburban newspapers and weekly and monthly magazines, as well as several dailies and weeklies in foreign languages. *Chicago Commerce,* a monthly, and *Crain's Chicago Business* carry economic and financial news. The magazine *Chicago* features general articles, stories of local interest, and entertainment notes. Chicago has numerous television and radio broadcasting stations; the public television station, WTTW, was one of the nation's pioneers in educational programming.

History

SETTLEMENT AND EARLY ACTIVITY

French explorers

In 1673 the French explorers Louis Jolliet and Jacques Marquette followed an Indian portage to the mudflats over which a Y-shaped river flowed. It emptied into Lake Michigan, while its arms reached nearly to the drainage basin of the Mississippi River system, thus virtually linking two great North American waterways. The meaning of the Indian name for the region remains disputed—among the possibilities are skunk, wild onion, or powerful.

Trappers, traders, and adventurers used the area for portage and barter throughout the 18th century. The first known non-Indian settler was Jean Baptiste Point Sable (or Pointe du Sable), son of a wealthy French merchant who had moved to Haiti and married a black woman there. Sable settled in the Great Lakes area in the 1770s. In 1795 the United States obtained a six-mile-square area about the river mouth.

Ft. Dearborn, built in 1803, was destroyed in 1812 and all but one of its military and civilian population were killed in an Indian raid. The fort was rebuilt in 1816 and was occupied until the 1830s. Outside its walls a cluster of traders' shacks and log cabins were built, but the settlement attracted little interest even after Illinois, with most of its population in the central and southern regions, became a state in 1818.

The opening of the Erie Canal in 1825, joining the Atlantic states and the Great Lakes, shifted the main axis of westward movement northward from the Ohio River route. Soon afterward, Chicago became the principal western terminus. The county of Cook located its seat at the small community, and the regional federal land office opened there. Numerous retail stores opened to outfit newcomers to the West, and the volume of animal pelts and products for Eastern markets increased. In 1837, the year Chicago became incorporated as a city, its population was about 4,200.

Emergence as a rail centre

Chicago's geographic potentiality as a water gateway was fulfilled by completion in 1848 of the Illinois and Michigan Canal, linking the Great Lakes and Mississippi systems. A pair of railroad lines from the East tied into Chicago in 1852, and by 1856 it had become the nation's chief rail centre. A belt line connected the radiating trunk lines by 1856, and commuter service to outlying neighbourhoods and suburbs began.

GROWTH AND DEVELOPMENT

Explosive economic growth. Industry followed the rails. By the late 1850s lake vessels carried iron ore from the Upper Michigan ranges to the blast furnaces of Chicago. Chicago became the nation's major lumber-distributing centre by the 1880s. The railroads brought farm produce from west and south, and Chicago's Board of Trade became the nerve centre of the commodities market. The railroads also hauled cattle, hogs, and sheep to Chicago for slaughtering and packing. The consolidated Union Stock Yards, largely bankrolled by nine railroads and the owners of several other Chicago stockyards, opened on Christmas Day 1865.

Chicago emerged as the major city of the Midwest. Its 1880 census reported more than 500,000 inhabitants, a 17-fold increase over 1850; by 1870 it had exceeded St. Louis, Mo., in population. It was the site of the 1860 Republican National Convention at which Illinoisan Abraham Lincoln won the presidential nomination. Both Americans and northern European immigrants, drawn by Chicago's factories and carried by the rail network that was anchored in Chicago, continued to pour into the city.

The Great Chicago Fire

Four square miles of Chicago, including the business district, were destroyed by fire on October 8–10, 1871. Starting in the southwest, fed by wooden buildings and pavements and favoured by a long dry spell, flames spread northeastward, leaping the Chicago River and dying out only when they reached Lake Michigan. About 250 lives were lost, some 90,000 people were made homeless, and almost $200,000,000 in property was destroyed.

The rebuilt city and its people. Much of the city's physical infrastructure remained, however, including its water-supply and sewage systems and transportation facilities. Chicago rebuilt rapidly in a similar pattern, although with buildings that were more modern and in conformance with new fire regulations.

The central business district, bounded by the Chicago River to the north and west and by the railroad along the lakeshore to the east, held the major department stores, the larger banks, the Board of Trade, the regional headquarters of rising national corporations, and the centres of commerce, law, and government. The district was the birthplace of the steel-frame skyscraper. Completion of the Home Insurance Building in 1885 led during the next nine years to the construction of 21 buildings ranging from 12 to 16 stories throughout the downtown area. Commuter railroads, horse, cable, and electric street railways, and elevated rapid-transit lines served the Loop.

The Lake Michigan shore became the centre for the homes and civic pursuits of Chicago's economic and social elite. Lake Shore Drive north of the Loop emerged as the mainline for society—the Gold Coast, it was soon nicknamed. Although blighted by the Illinois Central Railroad

yards, the waterfront east of the Loop was nevertheless landscaped and named Grant Park.

Heavy industry, warehouses, and rail yards crowded the banks of the Chicago River. Industrial pockets also existed at Chicago's outskirts. At the far south, where the Calumet River meets Lake Michigan, steel mills drew a polyglot community of blue-collar workers and their families. The Union Stock Yards dominated another South Side area, Back-of-the-Yards, made infamous in Upton Sinclair's scathing novel of industrial oppression, *The Jungle* (1906). Public health and sanitary conditions were an outrage: until 1900 Lake Michigan both supplied fresh water to Chicago and received its untreated sewage, a condition probably responsible for the city's frequent epidemics.

The second wave of foreign immigrants

Many of the working families arrived in the second great wave of European immigration: Russian Jews, Italians, Poles, Serbs, Croatians, Bohemians, and other groups from southern and eastern Europe. The 1890 and 1900 censuses showed that more than three-fourths of Chicago's population was made up of the foreign-born and their children.

The working districts were fertile ground for social action. The labour movement left the mark of its early attempts at industrial organizing: the Haymarket Riot of 1886, in which workers and lawmen alike died; and an 1894 strike against the Pullman Palace Car Company, led by pioneer organizer Eugene V. Debs and others. Social work was another influence: Jane Addams and her followers at Hull House, a West Side settlement, tried to improve the wretched conditions of housing and health there.

In 1889 Chicago annexed numerous inner suburbs, doubling its area and its population (to almost 1,100,000) and surpassing Philadelphia as America's second most populous city. By 1900 it was a centre of nearly all parts of the U.S. economy as well as of social insurgency and reform, immigration, education, and even culture. Chicago also had developed a brawling spirit evident not only along the dingy streets of the immigrant ghettos but also in corporate boardrooms and in the most elegant brothel in the nation, which entertained royalty from abroad and millionaires from the newly sprawling suburbs.

This Chicago was particularly striking to writers and visitors. "I have struck a city—a real city—and they call it Chicago," wrote Rudyard Kipling. "The other places don't count." And, he continued, "Having seen it, I urgently desire never to see it again. It is inhabited by savages."

Symbols of civic consolidation. A major expression of the city's character was the Plan of Chicago (1909), by Daniel H. Burnham and Edward H. Bennett, which took the general outlines of turn-of-the-century Chicago, added the notions of style possessed by the city's industrial and mercantile elite, and presented a vision of the future. The

The World's Columbian Exposition of 1893

plan was inspired by the 1893 World's Columbian Exposition celebrating the 400th anniversary of the discovery of America. Built on the Midway Plaisance adjacent to the University of Chicago, the exposition's buildings have been called a stylistic union of Classical Greece, Imperial Rome, Renaissance Italy, and Bourbon Paris.

Nonetheless, the exposition stimulated activity in city planning not only in Chicago but also throughout the world. The Classicism of the exposition was in marked contrast, however, to the modern Chicago School of architecture, and the two trends proceeded concurrently during the following decades. Chicago became a world centre of architectural innovation in the late 19th and early 20th centuries, with many notable buildings by Dankmar Adler, Louis Sullivan, Frank Lloyd Wright, and Henry H. Richardson.

The Burnham Plan, as it came to be called, proposed many subsequently developed features: park areas along Lake Michigan that included beaches, boulevards, and yacht basins; a belt of forest preserves rimming the city for recreation; the widening of arterial streets; a civic centre; and a double-decked boulevard in the central area along the Chicago River. Until 1939 the quasi-official Chicago Plan Commission promoted individual features of the plan, which, like Burnham's admonition, "Make no little plans," came to have a profound effect on Chicago.

The 20th century. Chicago's population growth was slower in the 20th century, though industrial expansion associated with World Wars I and II and the postwar prosperity continued to attract newcomers. Most pronounced was the influx of blacks from the South seeking industrial employment. A building boom in the city and suburbs terminated abruptly following the stock-market collapse of 1929, and during the depression years of the 1930s the population increased only slightly. Possibly contributing to this slowed growth were the worldwide notoriety of Chicago (only in part deserved) as the playground of underworld figures during the Prohibition era, the failure of several Chicago banks during the 1930s, and the allegedly powerful grip of criminal syndicates on many aspects of economic and political life. In contrast, however, the suburban population increased rapidly during this period.

After World War II, construction was slow to resume until Daley's election in 1955. Massive rebuilding programs became a hallmark of his terms in office, including an almost total alteration of the skyline of the Loop and adjacent areas. The downtown area continued as the centre for offices but suffered from a decline in other functions—including retailing, entertainment, and wholesale distribution—while those activities expanded rapidly on the periphery and in suburban areas. By 1970 the city, for the first time, had less than half of the metropolitan population. Chicago's population, in decline since the 1950s, reached its ebb in 1990, after which it stabilized.

Meanwhile, the city has experienced a rebirth. Construction in downtown and along North Michigan Avenue has added dozens of gleaming skyscrapers. Neighbourhoods, especially on the North Side, have been gentrified, and families have stayed in the city rather than move to the suburbs. In the areas adjacent to downtown hundreds of townhouses and apartments have been built, and old buildings have been turned into lofts and galleries. The entertainment scene in the Loop was revitalized in the 1990s with the creation of a new theatre district.

BIBLIOGRAPHY. General works include IRVING CUTLER, *Chicago: Metropolis of the Mid-Continent,* 3rd ed. (1982); and ROSEMARY K. ADAMS (ed.), *A Wild Kind of Boldness: The Chicago History Reader* (1998), a general anthology. *Chicago* (monthly) provides articles of local interest and reviews of cultural and entertainment events in the region.

Historical development of the city and region are detailed in HAROLD M. MAYER and RICHARD C. WADE, *Chicago: Growth of a Metropolis* (1969); DONALD MILLER, *City of the Century: The Epic of Chicago and the Making of America* (1996); WILLIAM CRONON, *Nature's Metropolis: Chicago and the Great West* (1991), a history of ecological change; and DANIEL BLUESTONE, *Constructing Chicago* (1991), a look at Chicago's development before World War I. DANIEL H. BURNHAM and EDWARD H. BENNETT, *Plan of Chicago* (1909, reissued 1993), is also useful. Aspects of Chicago history are covered in HERMAN KOGAN and ROBERT CROMIE, *The Great Fire: Chicago, 1871* (1971); ROSS MILLER, *American Apocalypse: The Great Fire and the Myth of Chicago* (1990), an account of Chicago's redevelopment, with a focus on the literature and architecture of that period; HAROLD L. PLATT, *The Electric City* (1991), a history of the electrification of Chicago and its effect on urban development; and LOIS WILLE, *Forever Open, Clear, and Free: The Struggle for Chicago's Lakefront,* 2nd ed. (1991).

Ethnic aspects are covered in CHICAGO DEPT. OF DEVELOPMENT AND PLANNING, *Historic City: The Settlement of Chicago* (1976); MELVIN G. HOLLI and PETER D'A. JONES (eds.), *Ethnic Chicago,* 4th ed. (1994); and GREGORY D. SQUIRES *et al., Chicago: Race, Class, and the Response to Urban Decline* (1987).

Materials on Chicago politics and government include PAUL M. GREEN and MELVIN G. HOLLI, *The Mayors: The Chicago Political Tradition,* rev. ed. (1995); MIKE ROYKO, *Boss* (1971, reissued 1988), on the Democratic Party organization of Mayor Richard J. Daley; and SAMUEL K. GOVE and LOUIS H. MASOTTI (eds.), *After Daley: Chicago Politics in Transition* (1982), an anthology; and GARY RIVLIN, *Fire on the Prairie: Chicago's Harold Washington and the Politics of Race* (1992).

The city's architectural heritage is covered in two exhibition catalogs: JOHN ZUKOWSKY (ed.), *Chicago Architecture, 1872–1922: Birth of a Metropolis* (1987), and *Chicago Architecture and Design, 1923–1993: Reconfiguration of an American Metropolis* (1993), with substantive essays and many illustrations. DOMINIC A. PACYGA and ELLEN SKERRETT, *Chicago, City of Neighborhoods: Histories & Tours* (1986), combines history, ethnic interest, and architecture; and FRANK A. RANDALL, *History of the Development of Building Construction in Chicago,* 2nd ed., rev. and expanded by JOHN D. RANDALL (1999), is the best source on individual structures. (H.M.M./Ed.)

Childhood Diseases and Disorders

The term childhood diseases denotes those diseases that characteristically occur during an age span that begins with the fetus and extends through adolescence. This is a period typified by change, both in the child himself and in his immediate environment. Changes in the child related to growth and development are so striking that it is almost as if the child were a series of distinct yet related individuals as he passes through infancy, childhood, and adolescence. Changes in the environment occur as the surroundings and contacts of a totally dependent infant become those of a progressively more independent child and adolescent. Health and disease during the period from conception to adolescence must be understood against this backdrop of changes.

Although, for the most part, the diseases of childhood are similar to those of the adult, there are several important differences. For example, certain specific disorders, such as precocious puberty, are unique to children; others, such as acute nephritis—inflammation of the kidney—are common in children and infrequent in adults. At the same time, some diseases that are common in adults are infrequent in children. These include essential hypertension (high blood pressure of unknown cause) and gout. Finally, a major segment of pediatric care concerns the treatment and prevention of congenital anomalies, both functional and structural.

Apart from variations in disease due to differences between children and adults, certain other features of diseases in children need to be emphasized. Infectious disorders are prevalent and remain a leading cause of death, although individual illnesses are often mild and of minor consequence. Most instances of the common communicable diseases, such as measles, chicken pox, and mumps, are encountered in childhood. Disorders of nutrition, still of great concern, especially but not exclusively in developing countries, are of extreme importance to the growing and developing child. The unique nutritional requirements of children make them unusually susceptible to deficiency states: vitamin-D deficiency causes rickets, a common disorder of children in developing countries, and only rarely causes any disease in adults. The major environmental hazards that endanger the health of young children are either unavoidable, as in air pollution, or accidental, as in poisoning and in traffic injuries. Older children, especially adolescents, are exposed, as are adults, to environmental hazards that they deliberately seek, such as cigarette smoking and the use of alcohol and other drugs.

This article reviews the scope of diseases that affect children, with particular emphasis on the ways in which the unique attributes of the growing child and special aspects of his environment serve to modify the course, effects, and treatment of particular diseases.

The article is divided into the following sections:

DIAGNOSIS AND GENERAL CONSIDERATIONS OF TREATMENT AND PREVENTION

Diagnosis of the diseases of childhood involves special considerations and techniques; for example, in evaluating genetic disorders, not only the patient but his entire family may need to be examined. Inapparent environmental causes of diseases, such as poisonings, must be considered and investigated thoroughly, by methods that at times resemble those of a detective. Diseases of the fetus may derive directly from disorders of the mother or may be caused by drugs administered to her. Diagnostic techniques have been developed that permit sophisticated examination of the fetus despite its apparent inaccessibility. The withdrawal of a small amount of the amniotic fluid that surrounds the fetus permits examination of fetal cells as well as the fluid itself. Chromosomal and biochemical studies at various stages of development may help to anticipate problems in the postnatal period; they may indicate the need for immediate treatment of the fetus by such techniques as blood transfusion; or they may lead to the decision to terminate pregnancy because serious, untreatable disease has been recognized. Other specialized techniques permit examination of the fetus by X ray and ultrasound, and by electrocardiography and electroencephalography (methods for observing and recording the electrical activity of the heart and the brain, respectively). Fetal blood can be obtained for analysis, and certain techniques permit direct viewing of the fetus.

In examination of the infant, inaccessibility is no special problem, but his small size and limited ability to communicate require special techniques and skills. Of even more importance, however, is the fact that adult norms cannot be applied to younger age groups. Pediatric diagnosis requires knowledge of each stage of development, with regard not only to body size but also to body proportions, sexual development, the development and function of organs, biochemical composition of the body fluids, and the activity of enzymes. The development of psychological and intellectual function is equally complex and requires special understanding. Since the various periods of growth

Stages of growth and development

and development differ so markedly from one another, they are divided for convenience into the following stages: intrauterine (the period before birth), neonatal (first four weeks), infant (first year), preschool (one to five years), early school (six to 10 years for girls, six to 12 for boys), prepubescent (10 to 12 for girls, 12 to 14 for boys), and adolescent (12 to 18 for girls, 14 to 20 for boys). Only if appropriate norms are established for each stage of development can the child's condition be adequately evaluated and the results of diagnostic tests properly interpreted. Thus, it is of no concern if a 12-month-old infant is unable to walk alone, although some infants are able to do so at nine months of age. The crucial question is at what age one becomes concerned if a developmental milestone has not been reached. Five-year-old boys average 44 pounds (20 kilograms) in weight but may vary from 33 to 53 pounds (15 to 24 kilograms). The hemoglobin level that is of no concern in the three-month-old infant may reflect a serious state of anemia in the older child. The blood levels of certain enzymes and minerals differ markedly in the rapidly growing child from those in the late adolescent, whose growth is almost complete. Failure of a 15-year-old girl to have achieved menarche (the beginning of menstruation) may be indicative of no abnormality in sexual development but requires careful evaluation.

Treatment of childhood disease requires similar considerations with regard to various stages of growth and development. Variation in drug dosage, for example, is based not only on body size but also on the distribution of the drug within the body, its rate of metabolism, and its rate of excretion, all of which change during various stages of development. The inability of infants and small children to swallow pills and capsules necessitates the use of other forms and alternate routes of administration. Drug toxicity of importance at one stage of development may be of no concern at another; for example, the commonly used antibiotic tetracycline is best avoided in treatment of the child younger than age 10 because it is deposited in teeth, in which enamel is also being deposited, and stains them. When permanent teeth are fully formed, the deposition of tetracycline no longer occurs. The delayed consequences of certain forms of treatment, especially with radioactive isotopes—substances that give off radiation in the process of breaking down into other substances—might be of no consequence in the case of an elderly person with a life expectancy of 10 or 20 years but might deter a physician from the use of such treatments for the infant with his whole life in front of him. Finally, the nutritional requirements of the growing child must be considered when treatment of disease requires modification of the diet or administration of drugs that may affect the absorption or metabolism of essential nutrients.

Prognosis

The outlook for recovery from diseases in children is often better than it is for adults, since the child's additional capacity of growth may counteract the adverse influences of disease. The bone fracture that results in permanent deformity in the adult, for example, may heal with complete structural normality in the child, as continued growth results in remodeling and reshaping of the bone. Ultimately, the infant who has one kidney removed because of infection or tumour most likely will have entirely normal renal (kidney) function because the remaining kidney will increase its size and functional capacity with growth. In contrast, removal of one kidney in the adult usually results in a residual functional capacity equal to 70 to 75 percent of that of two normal kidneys.

Thus, being in a period of rapid growth and development may favourably affect the child's recovery in the course of a disease. The converse may also be true, however. The rapidly growing and maturing central nervous system, for example, is particularly susceptible to injury during the first two or three years of life; also, adolescents may react unfavourably to psychological stresses that are tolerated readily by more mature individuals.

Prevention of childhood disease

In the general consideration of childhood diseases, a final aspect that merits emphasis is the role of prevention. The major factors responsible for the decline in infant and childhood mortality rates over the past decades have been the development and application of preventive measures. By the late 20th century, in most countries the death rate for infants under one year of age had decreased until it was scarcely more than a 10th of the rate in the 1930s. Socioeconomic factors—such as better maternal nutrition and obstetrical care and improved housing, water supplies, and sewage disposal—have been of prime importance in this decline, together with better hygiene at home, safer infant feeding techniques, and widespread immunization against common infectious diseases. In comparison to the favourable effect of these and other preventive measures, an increased capacity to treat diseases, even with such powerful tools as the antibiotic drugs, has had relatively little impact. In the developed countries, where the most common causes of childhood morbidity and mortality are accidents, prevention depends upon a willingness to design and modify communities and homes to make them safer for children. Just as important as the development of public health measures is their practical application; underutilization of established procedures and techniques for prevention of disease is a major health problem.

DISEASE-AFFECTING DIFFERENCES BETWEEN CHILDREN AND ADULTS

Disturbances in growth may be among the most striking consequences of disease in children. An obvious example of this effect is total growth failure, which is seen in almost every serious disease of infants and children. Local retardation or disturbance in growth patterns may be equally striking. Osteomyelitis, an infection of bone, may, for example, result in retardation or cessation of growth at that site, with subsequent severe asymmetry between the affected limb and its normal counterpart. Enlargement of the heart as a result of cardiac disease may cause gross distortion of the chest, as the growing ribs adapt to the abnormal shape of the heart.

Many differences in the manifestations of disease in children and adults can be ascribed to differences in anatomical structure and in biochemical, immunological, and physiological function. Less well understood are the consequences of differences in psychological function. In general, the younger the child, the more striking these differences are.

Anatomical differences. Not only is the child's body smaller than that of the adult, but it has different proportions; for example, the sitting height of the newborn infant represents about 70 percent of total body length. With rapid growth of the extremities, sitting height decreases to about 57 percent of the body length at three years of age and, finally, as growth proceeds more slowly, to the adult proportion of about 50 percent. Growth and development are not necessarily smooth, continuous processes. Weight and height increase rapidly in infancy and at puberty; for example, the head completes half its total growth in the first year of life, and by the age of two years the child has reached half his adult height. In addition to differences in proportion and size, there are marked differences in body composition between children and adults. As examples, in newborn infants muscle mass constitutes approximately 25 percent of total body weight, compared to 43 percent in adults. Total body water, which accounts for 90 percent of early fetal weight, represents 75 percent of body weight at birth, drops to about 60 percent by one year of age, and then declines gradually to reach the adult figure of 55 percent. The higher proportion of body water, due almost entirely to a relatively greater volume of fluid outside the cells, affects the response of the infant, particularly to disturbances in water balance.

Differences in body composition

There are many examples of differences in anatomical structure that affect manifestations of disease. In assessing the health of the infant with cardiac or pulmonary (lung) disease, the thinner chest wall, the relatively more horizontal position of the heart, and the more rapid cardiac and respiratory rates must be taken into account. The thin abdominal wall of the infant permits palpation—examination by touching with the fingers—of the kidneys, whereas in older subjects the kidneys usually can be felt only if they are abnormally large. In the infant, with the bones of the skull still not fused together, obstruction of the flow of cerebrospinal fluid may result in striking enlargement

of the head, a condition referred to as hydrocephalus. In the older child, when the skull sutures have fused, such enlargement is not possible, and the manifestations of spinal-fluid obstruction are similar to those of the adult, including severe headache and visual difficulties as a result of increased intracranial pressure. The primary manifestation of mumps is a painful swelling of the parotid and other salivary glands. In adolescents, involvement of the testes or ovaries occurs only rarely, a phenomenon related in some way to the immaturity of these organs. In the adult, particularly in the male, severe sex-gland involvement is common.

Physiological differences. Physiological differences between children and adults that cause differences in the manifestations of disease include all the various functional, endocrine, and metabolic features of the growing and maturing organism. A major characteristic in this regard is the limited ability of the infant to maintain homeostasis (a stable internal environment) during illness because of his greater metabolic and nutritive requirements. Moreover, most of the first year of life is characterized by immaturity of renal function, the capacity of the kidneys to respond to the stresses of disease being less than later in life. The baby with severe diarrhea, for example, cannot conserve water well enough and may become dehydrated. With any degree of stress, metabolic abnormalities are likely to be more severe in the infant than in the older child.

The liver of the newborn child also demonstrates certain features of immaturity. Of particular importance is its limited capacity to excrete bilirubin, a product of the breaking down of hemoglobin (the oxygen-carrying pigment of red blood cells). In certain conditions in which there is a rapid rate of destruction of red blood cells, the inability of the liver to excrete the added load of bilirubin may result in a large increase in the concentration of this substance in the blood; the bilirubin concentration, if high enough, can cause severe brain damage known as kernicterus. Since immaturity of the brain also contributes to the infant's increased susceptibility to this disorder, kernicterus is rarely encountered outside of the neonatal period, even in subjects with severe liver disease.

The ability of the young infant to metabolize and to excrete certain drugs is limited by the immaturity of the liver and of the kidney, and drug dosage must be adjusted accordingly.

Immunologic responsiveness

The immunologic system of the body is responsible for the defense against disease. This highly complex system involves the production of antibodies (proteins that can recognize and attack specific infectious agents); the action of granulocytes and macrophages, cells that destroy infecting organisms by ingesting them (a process called phagocytosis); and the function of a variety of cellular mechanisms involving the complement system (complement is an enzyme-like substance in the blood). Antibody production in the infant is qualitatively and quantitatively different from that in the older child and adult. Although the differences in antibody response cannot be related specifically to differences in the capacity of the infant to withstand infection, they certainly must play some role. On the other hand, many of the clinical features of infectious disease occurring during the first two or three years of life appear to be related to the fact that these are infections occurring for the first time.

Another difference in immunologic response between children and adults is in the functioning of the reticuloendothelial system. This system, which is composed of the macrophages found in the lymph nodes, spleen, and other lymphatic tissues, is relatively more active in childhood. Since macrophages ingest infectious organisms, children with coryza or sore throats commonly have swollen lymph "glands" visible and palpable in the neck. Similarly, their tonsils and adenoids, which are lymphatic tissues, swell rapidly in response to mild infections.

DISORDERS PRESENT AT BIRTH

Diseases transmitted through the placenta or due to placental dysfunction. Infectious diseases of the fetus are caused by many different types of organisms, including viruses, bacteria, spirochetes, and protozoa (*e.g.,* toxoplasmosis). Most of these infections are the result of infection of the mother, the infectious agents being transmitted through the placenta (the temporary organ by means of which the fetus receives nourishment and discharges waste) by way of fetal circulation. Bacterial infection is most often associated with premature rupture of the membranes and infection of the amniotic fluid.

Maternal rubella (German measles) occurring during the first eight weeks of pregnancy is associated with congenital malformation of the fetus in more than 50 percent of cases, the figure decreasing to about 20 percent by the 16th week and dropping sharply thereafter. Infection of the fetus with a virus of the cytomegalovirus type involves many organs, has a high fatality rate, and may result in severe brain damage in fetuses who survive. Infection by the intracellular parasite *Toxoplasma gondii* produces a disease called toxoplasmosis, which may cause death or may result in microcephalus (abnormal smallness of the head), hydrocephalus (excessive accumulation of fluid in the brain cavities), or mental retardation. Congenital syphilis may have a variety of effects in the infant, including involvement of the skin, liver, spleen, lymph nodes, and kidneys. Malformations of the bones and teeth appear later, and severe involvement of the central nervous system may become apparent after many years.

Just as infectious agents may cross the placenta, so also most drugs administered to the mother may pass through the placenta and have important effects on the fetus. A most dramatic and devastating example of this effect occurred in Europe during the early 1960s, when the birth of thousands of infants with absent or short limbs resulted from the maternal ingestion of the apparently harmless drug thalidomide. Anesthetics, analgesics (pain relievers), sedatives, antihypertensive drugs, and antibiotics all may have adverse effects on the fetus. Congenital goitres (enlargement of the thyroid) have been produced by administration of antithyroid drugs to the mother. It is now clear that adverse effects on the fetus must be considered whenever drug therapy of the mother is contemplated.

The abuse of narcotics or alcohol by the mother can also lead to dire fetal consequences. Infants born to mothers addicted to heroin, morphine, or other opiates commonly share their mothers' addiction and suffer withdrawal symptoms within 72 hours of birth. Many infants of alcoholic mothers are afflicted with a combination of malformations, known as the fetal alcohol syndrome, which include mental retardation, growth retardation, and microcephaly.

The entire nutrient supply of the fetus derives from the mother. Although maternal deficiency states may, therefore, be reflected by parallel deficiencies in the fetus, in general the needs of the fetus will be met ahead of those of the mother, and an adequate amount of a given nutrient may be supplied to the fetus, despite maternal deficiency. Mild to moderate deficiencies of iron or calcium in the mother, for example, are not usually associated with deficiencies in the fetus. On the other hand, protein and caloric malnutrition may be associated with decreased fetal size.

Placental insufficiency

Deficiencies in the fetus may also arise from placental dysfunction (malfunctioning). The consequences of abnormalities of the placenta depend upon the time of onset and the severity of placental inadequacy. Serious placental insufficiency early in pregnancy may result in the death of the fetus. It is also likely that placental insufficiency can be a factor in decreasing fetal growth. Toward the end of pregnancy, placental dysfunction is associated with premature delivery or evidence of varying degrees of fetal distress, ranging from yellow staining of the skin to fetal wasting and to signs of severe lack of oxygen.

Injuries incurred during birth. The physical trauma of delivery may result in a number of injuries to the infant. Of little consequence is the diffuse soft-tissue sweiling of the scalp referred to as caput succedaneum. Difficult delivery may result in more extensive bruising, abrasions, and edema—particularly after breech delivery; however, serious harm is rare. Bleeding under the periosteum (the covering membrane) of the skull produces a large swelling in 1 to 2 percent of babies, and in some it is associated with a small fracture of the underlying skull; fortunately, spontaneous healing occurs speedily. Injuries to the spinal

cord are rare, but injuries of peripheral nerves as a result of traction on the head are not uncommon. Such injuries include Erb's paralysis, with weakness of the arm and shoulder because of damage to the fifth and sixth cervical nerves. Injury to the phrenic nerve, with paralysis of the diaphragm—the muscular partition between the chest and the abdomen—and facial-nerve injury resulting in facial palsy also are encountered. In the vast majority of such instances of peripheral-nerve injury, recovery is complete.

An extremely important form of birth injury is that associated with lack of oxygen (anoxia). Fetal anoxia may occur from inadequate oxygenation of the mother, low maternal blood pressure, or abnormalities in the uterus, placenta, or umbilical cord that result in inadequate blood flow to the fetus. After birth, anoxia may result from blood loss, shock, or inadequate respiration. Clinical manifestations include decreased activity, slowing of the heart, and blueness of the skin (cyanosis). Severe anoxia may cause death of the newborn, although recovery is more common. The major significance of anoxia is that it may result in brain damage if prolonged more than a few minutes.

Definition of prematurity

Prematurity and low birth weight. The usual length of the gestation period is 40 weeks. Infants born prior to 37 weeks of gestation are considered to have been born early and are referred to as preterm or premature. Infants who at birth weigh 2,500 grams (about 5.5 pounds) or less are considered to be of low birth weight and either are prematurely born or have had less than the expected rate of growth within the uterus.

Infants whose weight is low at birth account for as many as 10 to 15 percent of births among low socioeconomic groups and as few as 4 to 5 percent of births among those of higher socioeconomic status. Clinical examination of the baby helps to differentiate between the preterm baby and the small baby born at term, but such determination of gestational age (the age from conception to birth) is not precise. The correct classification of the baby is important because maturity, in terms of gestational age, is a major factor determining the ease with which the baby will adapt to life outside the uterus. In the infant born too early, many organ systems will not be fully developed. The preterm infant who is large and only slightly immature does as well as the full-term infant, but the very small preterm infant, below 1,000 grams (about 35 ounces) in weight, has a high fatality rate and is prone to many complications.

The complications encountered in coping with extrauterine existence involve primarily the respiratory and gastrointestinal systems. In addition to anatomical immaturity of the lungs, a handicapping feature of the premature infant may be a lack of a substance called a surfactant, which plays an important role in permitting the air spaces, or alveoli, of the lungs to remain open. Surfactant appears in some fetuses at 24 weeks' gestation but is absent in others until about 30 weeks. Because of these respiratory handicaps—particularly the lack of surfactant—many premature infants suffer from respiratory distress syndrome, a condition described below under *Respiratory disorders.*

Inability to suck adequately and limitations in the capacity to digest foodstuffs and absorb them through the intestinal tract provide other serious handicaps for the premature infant. To circumvent these problems, infants may be fed (by stomach tube) specially prepared formulas tolerated by even the smallest of babies.

The relatively large surface area of the small infant and his inability to maintain body temperature may require his being kept in an incubator. In addition to temperature control, the incubator makes it possible to provide extra oxygen to the infant who has respiratory difficulties, although this must be done with care because excessive oxygen may lead to damage to the eyes, a condition known as retrolental fibroplasia.

Survival of premature infants

As indicated above, the prematurely born infant is considerably less likely to survive than are full-term infants. Premature infants, accounting for less than 8 percent of all live births, account for two-thirds of infant deaths. Even after the first year of life, the mortality rate among infants with low birth weights is greater than among infants with birth weights above 2,500 grams. The cause of this increased rate is not completely known, although a higher prevalence of congenital anomalies accounts for some of the difference. Moreover, retarded intellectual development and other abnormalities of the nervous system are more common in such infants, particularly those with birth weights of less than 1,500 grams (3.3 pounds). The majority of infants with low birth weights remain small throughout the childhood years, which may reflect a continued pattern of slow growth, first evidenced in the uterus.

Metabolic disturbances. Infants of diabetic mothers represent a unique group with special metabolic problems. Intrauterine death is common and unexplained. The placenta is often abnormal. The infants at birth generally are large and have large organs, a condition referred to as macrosomia. Respiratory distress and low levels of sugar in the blood (hypoglycemia) are common complications.

Neonatal hypoglycemia is a relatively common disorder, particularly among infants whose birth weight is low. Fifteen percent of hypoglycemic infants have associated abnormalities of the central nervous system. In most instances hypoglycemia is transient and responds readily to treatment.

Jaundice in the newborn is ordinarily related to an imbalance between the rate of destruction of red blood cells and the metabolism of hemoglobin to bilirubin and the rate of excretion of bilirubin in the bile; there is a resultant temporary elevation of bilirubin level in the blood. Jaundice may, however, be due to septicemia, to several different diseases of the liver, or to obstruction of the ducts through which bile flows into the intestinal tract. Abnormally high bilirubin levels have also been found in association with breast feeding; it is an extremely rare condition resulting from the presence of an unusual substance in the milk.

The significance of jaundice depends on the underlying cause and the amount of excess bilirubin in the blood. In extreme cases, bilirubin can be deposited in brain cells, resulting, as mentioned above, in severe nerve-cell damage, called kernicterus. This condition, which may lead to deafness and cerebral palsy, is encountered most often in infants with erythroblastosis fetalis, a blood disorder discussed below. Brain damage from an excess amount of bilirubin can usually be prevented by means of exchange transfusions (in which most of the infant's blood is replaced with blood from donors), which in the most severe cases may need to be repeated many times.

Kernicterus

Tetany of the newborn, a condition that appears within a few days after birth, is characterized by increased neuromuscular irritability, with muscular twitching, tremors, and convulsions. In most cases, the blood concentration of calcium is low, and that of inorganic phosphate is high. In some infants the disorder appears to be due to a low concentration of magnesium in the blood. The infant's condition is usually dramatically improved by the intravenous administration of calcium. The disorder is transient, so that treatment with oral calcium supplements can be discontinued after one or two weeks.

In contrast to the metabolic disturbances described above, which are generally transient conditions of the newborn, are the long-term disorders known as the inborn errors of metabolism. These result from the absence of a functional enzyme in a particular metabolic pathway. Because of this "enzyme block," there is a deficiency in the products of the affected pathway and an excessive build-up of harmful chemicals that cannot be processed normally. Inborn errors of metabolism are genetically determined, and most are very rare. Many lead to severe illness and brain damage unless effective and early treatment can be started. A well-known example is phenylketonuria, which can be detected by a simple blood-screening test (the Guthrie test) during the first week of life. Once identified, the affected infant is given a special diet that prevents brain damage and allows normal growth. The diet has to be continued until at least the age of 10 years, and some clinicians recommend that it be followed for life.

Inborn errors of metabolism

Infections. The newborn infant is subject to the ordinary infections and, in addition, to infection with commonly encountered organisms such as *Escherichia coli, Staphylococcus aureus,* and group B hemolytic streptococci, which are not usual causes of serious infection in

older age groups. Infection may be acquired in the uterus, during delivery, or later, in the nursery. Commonly encountered serious infections are pneumonia, meningitis (inflammation of the coverings of the brain and spinal cord), and septicemia (infection of the bloodstream). Often the infant shows few signs of the disease other than poor feeding, lethargy, pallor, or slight fever. Since the newborn infant's resistance to infection is poor, early diagnosis and treatment are particularly important. Often, treatment is given when infection is merely suspected.

Common infections

Congenital defects of each part of the immunologic system have been discovered. The most striking feature of these diseases is the inability of the patient to combat infection. Thus, untreated patients with some forms of agammaglobulinemia (lack of antibodies in the blood) may die from overwhelming infection in infancy or early childhood.

Respiratory disorders. Numerous abnormalities of respiratory function are common in the newborn infant. One of the most severe is respiratory distress syndrome (RDS; also called hyaline membrane disease). RDS occurs in 0.5 to 1 percent of all deliveries, and, as previously mentioned, is especially common in premature infants. In addition, it is encountered commonly in infants of diabetic mothers and after cesarean section (delivery through the wall of the mother's abdomen). RDS also occurs, albeit infrequently, in full-term infants without any apparent predisposing cause. Soon after birth, affected infants begin to take rapid, shallow breaths and can be shown by appropriate tests to be exchanging air (*i.e.,* absorbing oxygen and exhausting carbon dioxide) only poorly. Without expert treatment, they may die within a few hours or may have a protracted course over a period of several days, with later demise or gradual improvement and recovery. Treatment is directed at relieving the symptoms and includes correction of an associated acidosis, administration of oxygen, and assisting the infant to breathe, if necessary with a mechanical ventilation machine. With modern care, death has become less common.

Respiratory distress syndrome

Pneumonia is in infants a serious problem. The onset is either within hours after birth, in infants whose infection is contracted from the mother, or after 48 hours of life, when the infection is acquired after birth. Infants show signs of difficulty in breathing, and often there is an associated infection of the blood (septicemia). Treatment consists of the administration of carefully selected antibiotics in appropriate dosages and respiratory support.

Pneumonia

An infant may inhale meconium (a semisolid discharge from the infant's bowels) during the course of delivery, leading to obstruction of the upper airway. Clearing the airway with suction, the administration of oxygen, and general respiratory support are usually effective in promoting recovery within two to three days.

Leakage of air into the pleural space (between the membrane lining the chest and that enveloping the lungs and other thoracic organs), with consequent partial or complete collapse of the lung (pneumothorax), bleeding into the lung, and failure of expansion of the lung (atelectasis), also causes respiratory failure in the newborn infant. Prompt treatment is often necessary to ensure survival.

Cardiovascular disorders. Cardiovascular disturbances in the newborn are related primarily to congenital malformations that affect about seven out of every 1,000 infants. They vary from those that are incompatible with life to those that cause no illness and require no treatment. Sometimes the cause is known because of an association with a chromosomal disorder (*e.g.,* Down's syndrome and Turner's syndrome; see below); in a few the cause is maternal rubella infection. The lesions arise early in fetal development, and the result is usually either an obstruction of normal blood flow or an abnormal communication between different parts of the heart or the circulation. When the structural abnormality causes severe disturbance, heart failure results. The baby in heart failure may present such symptoms as a blue complexion (cyanosis), breathlessness, or feeding difficulties. Most congenital heart defects are associated with heart murmurs that can be heard with a stethoscope. The most common congenital lesion is a ventricular septal defect, which is a hole between the two lower chambers of the heart (the left and right ventricles). Many of these close spontaneously without treatment. Diagnosis of an infant with suspected congenital heart disease has been made surer and easier with the development of echocardiography. Most of the disorders that cause illness can be corrected by surgery, which—unless the defect is immediately life-threatening—is usually deferred until the child is older. For a fuller discussion of specific congenital cardiovascular defects, see CIRCULATION AND CIRCULATORY SYSTEMS: *Cardiovascular system diseases and disorders; Congenital heart disease.*

A specific cardiovascular problem common in the preterm infant is patent ductus arteriosus, which is the persistence of an essential feature of fetal circulation. The ductus arteriosus is a fetal blood vessel that connects the descending aorta and the pulmonary artery. It shunts blood from the lungs (which are nonfunctional in the fetus), channeling it toward the placenta (where oxygenation takes place). Normally, the ductus closes shortly after birth. When it remains patent (open) after birth, it functions as a shunt in the opposite direction, diverting blood from the aorta to the lungs. Thus, too much blood is delivered to the lungs, and the subsequent pulmonary congestion causes breathing difficulties. Drugs can be given to encourage the ductus to close. If drug treatment proves ineffective, the ductus may be closed surgically.

Blood disorders. The diseases affecting the blood of newborn infants include diseases of the red blood cells (particularly the anemias, which involve an inadequate level of functioning hemoglobin in the blood) and of the clotting factors (*e.g.,* hemophilia). These diseases and others that affect the blood of the newborn are discussed below, in the sections dealing with disorders associated with later infancy and childhood, and are covered in BLOOD: *Blood diseases.*

Erythroblastosis fetalis is a disease in which the red blood cells of the fetus are destroyed because of an incompatibility between the infant's blood and that of the mother. The severest form results from incompatibility between an Rh-negative mother and an Rh-positive fetus. If the mother has been sensitized (by previous exposure) to Rh-positive red blood cells, she will have circulating antibodies against the Rh factor. These antibodies can cross the placenta and destroy the red blood cells of her Rh-positive fetus. Unless the mother has been sensitized by blood transfusions, her first Rh-positive fetus is normally not affected. This is because her exposure to the fetal red blood cells is minimal until the delivery of the baby, when there is substantial transfer of fetal red blood cells to the maternal circulation. This exposure can sensitize the mother, and any future Rh-positive fetuses will be at risk. It is now standard procedure to administer anti-Rh serum promptly to an Rh-negative mother who has given birth to an Rh-positive child. The serum destroys any fetal red blood cells in her circulation before she becomes sensitized, thereby protecting future Rh-positive fetuses from erythroblastosis fetalis.

Gastrointestinal disorders. Vomiting, a common symptom among newborn infants, may be due to intestinal obstruction or to overfeeding or may occur without apparent cause. Continuous contraction of the muscle governing the opening between the stomach and the intestine may cause vomiting. This condition, called pyloric stenosis, may occur at any time in early infancy and usually requires surgical treatment.

The first bowel action and passage of meconium by the baby usually occurs within 12 hours. Delay may indicate an obstruction of the bowel. Important causes of obstruction are congenital narrowing (stenosis) or occlusion (atresia) of the intestine. These can occur at any site—from the duodenum (the first section of the small intestine) to the rectum and anus. Some babies are born with a small dimple or pit rather than a patent anus. Duodenal stenosis is particularly common in babies with Down's syndrome. Congenital obstructions of the intestines cause vomiting and constipation in early life; most can be corrected surgically.

Congenital bowel obstruction

Meconium ileus, intestinal obstruction by hard lumps of meconium, occurs almost exclusively in infants with cystic fibrosis, an inherited disease that is described below.

Recovery, except in some instances of perforation of the intestine, is the rule.

Kidney and urinary-tract disorders. The kidneys of the newborn infant are entirely capable of maintaining homeostasis, or balance, of fluids and electrolytes in normal circumstances, adapting readily, for example, to the various formulas utilized in infant feeding, despite the wide range of solute content and the consequent large variation in the excretory load imposed. (Electrolytes, in this context, are substances that become ionized in solution: that is, are given a positive or negative electrical charge.) In situations of stress, however, abnormalities in the regulation of salt and water balance and of acid–base metabolism are common. Limitations in the excretory capacity of the newborn infant's kidneys require adjustment of drug dosage and fluid therapy.

The most common disorders of the kidneys and urinary tract encountered in the neonatal period are congenital anomalies. Some, such as absence of one kidney, do not matter, since one healthy kidney will suffice; but other infants are born with no kidneys or with malformed (dysplastic) kidneys that function poorly. Polycystic disease of the kidneys is an example of a serious congenital abnormality. In this disorder, the kidneys contain numerous large cysts that severely impair renal function.

Congenital obstructions of the urinary tract—either of the ureter above the bladder or of the urethra below it—predispose the infant to urinary infection and to kidney damage. Failure of a newborn to pass urine within 12 hours of birth leads to a search for possible obstruction.

Nephritis (inflammation of the kidneys) is rare in the newborn. In one well-known type—congenital nephrosis—large amounts of protein are lost in the urine, with consequent development of severe, generalized edema. The outlook for recovery in congenital nephrosis and in other forms of nephritis in infants is extremely poor.

Infections of the kidneys and urinary tracts are difficult to recognize clinically in young infants. If, however, they are diagnosed early and treated promptly, such infections respond well to treatment, unless there is an associated congenital obstructive lesion.

Nervous-system disorders. Congenital malformations of the nervous system rank among the most common severe congenital abnormalities. A variety of brain malformations may occur, some incompatible with life (*e.g.*, anencephaly—the absence of the cerebral hemispheres), others resulting in permanent disability. Common brain malformations include microcephaly, an abnormally small head due to limited brain growth, and hydrocephalus, in which there is an increase in the volume of cerebrospinal fluid associated with increased pressure. The obvious evidence of the latter condition is the large size of the head. Some infants with hydrocephalus die before birth. After birth, the condition may arrest spontaneously. The major treatment is relief of pressure by diversion of the spinal fluid or by surgical correction of any obstruction. The prevention of progressive damage is the goal of therapy.

Spina bifida

Spina bifida is a congenital disorder in which the vertebral column fails to close over a portion of the spinal cord, usually in the lumbar region, leaving that section of cord unprotected. Part of the unprotected cord—nervous tissue, meninges (the cord's membranous covering), or both—may protrude through the defect in the vertebral column. Protrusion of the meninges, with or without neural elements, is frequently accompanied by hydrocephalus. The spinal-cord abnormality usually results in defective nerve function below the level of the lesion; thus weakness or paralysis of the legs and urinary incontinence are common.

Acquired conditions, including those secondary to insufficient oxygen and bleeding, have been mentioned above in the section on birth injuries. Meningitis (inflammation of the coverings of the brain and spinal cord) may occur in the newborn. Unfortunately, the diagnosis is often delayed because of the lack of characteristic symptoms and findings in infants.

Convulsions (seizures) are common in the newborn. These may result from damage to the brain during delivery or from infections and metabolic problems.

Endocrine disorders. Although rare, congenital defects of the endocrine (hormone-producing) glands can have severe consequences. Congenital hypothyroidism (subnormal secretion by the thyroid glands, also called cretinism) is an especially important endocrine disease of infancy in that failure to identify and treat it early may result in severe mental retardation. It is due either to an absence of the thyroid or to a metabolic disturbance in the function of the gland. Early diagnosis and proper therapy with thyroid drugs result in dramatic improvement, with rapid disappearance of all signs and symptoms of disease. In countries with well-developed health services, a drop of the newborn's blood is used in a chemical screening test for cretinism. Effective treatment thus can be initiated shortly after birth.

Congenital adrenal hyperplasia is a group of conditions in which there is a defect in the production of normal adrenocortical-steroid hormones (secretions of the cortex, or outer substance, of the adrenal glands). Excessive stimulation of the cortex of the adrenals by a pituitary hormone (adrenocorticotropic hormone, or ACTH) results in abnormal enlargement of the glands and overproduction of androgenic (masculinizing) adrenal hormones. As a result, there may be abnormal development of the genitalia of females in utero and evidence of excessive androgenic effect in either sex during infancy, with accelerated growth, premature appearance of pubic hair, and enlargement of the phallus.

Musculoskeletal disorders. Common congenital musculoskeletal defects include abnormalities of the feet and the hips. Classic clubfoot, or talipes equinovarus, is a congenital twisting of the foot in which the heel bends upward and the front part of the foot is turned inward and bent toward the heel. Correction usually involves the use of splints and plaster casts to force the foot into the correct position; severe cases may necessitate surgery. In talipes calcaneovalgus, the front part of the foot is bent upward and turned outward. This form of clubfoot generally results from mechanical pressure in the uterus having held the foot in an unusual posture. Passive stretching exercises usually can correct this condition, but stubborn cases may require the use of splints or casts.

Congenitally dislocated hips are associated with lax joints and are most common in girls born at term by breech delivery. The condition is usually detectable by careful clinical examination and, if diagnosed early, responds to simple treatment. If undetected until a two-year-old is noticed to walk with a limp, major surgery may be needed.

Skin disorders. The infant's skin has a thin epidermis and immature glands and is particularly susceptible to blistering and infection. Diaper, or napkin, rashes, which affect the areas of skin in contact with a wet diaper, are very common and can become severe when additional infection occurs.

There are many common birthmarks. Most result from either developmental anomalies of the blood vessels, called hemangiomas, or from an excess of pigment in the skin, called nevi. A common worry to parents is the "strawberry" hemangioma, which is red, raised, and unsightly. Although it may increase in size in the early weeks, it gradually fades away by the age of seven years. A Mongolian blue spot, usually on the buttocks or back, looks like a faint bruise and is a common pigmented birthmark in infants of black or Oriental stock. It fades and is rarely visible after the age of seven.

Chromosomal disorders. A normal person has 46 chromosomes, but sometimes developmental faults occur that result in the fetus' having extra chromosomes. Most of these abnormal fetuses result in miscarriages or stillbirth, but those with Down's syndrome (mongolism) commonly do survive. Down's syndrome occurs approximately once in every 600 births. The affected child carries an extra chromosome number 21 and has a characteristic appearance that includes a round skull; flat face; oblique eyes; small, drooping mouth; and a short, broad neck and hands. The main problem of Down's syndrome victims is moderate to severe mental retardation. As adults, most are incapable of leading independent lives. They also suffer from an excess of respiratory infections in early life and

have an increased incidence of serious congenital abnormalities. In developed countries, however, most of them grow up to be reasonably healthy adults, though their life expectancy is shorter than that of a normal person.

Disorders of the sex chromosomes are also common. These disturb the development of the gonads more than they influence the external genitalia; therefore, many of the conditions are not diagnosed until after puberty, when the child (or parents) becomes concerned about the lack of development of sexual characteristics. Normal girls have two X sex chromosomes. Those with Turner's syndrome have a single X chromosome. The syndrome may be detected early in life because the girls are short and have other visible characteristic features. The diagnosis can only be confirmed, however, by careful analysis of the chromosomes in the blood cells. These girls remain short, and secondary sexual characteristics do not appear unless additional hormones are given. Even then, an affected girl remains infertile because her uterus, vagina, and gonads are very small.

Turner's syndrome

Normal boys have one X chromosome and one Y sex chromosome. Those with Klinefelter's syndrome have an extra X chromosome. Although the condition occurs as often as Down's syndrome, it is not usually detected until the testicles fail to enlarge at puberty. The boys are healthy, but infertility is usual.

It is well documented that more males than females are affected by nonspecific mental handicaps and that in some families the males are regularly affected. Several different forms of mental handicap linked with the X chromosome in the male have been identified. In some of the affected males, a "fragile site" can be identified on the X chromosome with appropriate laboratory techniques. Such males are said to have the fragile-X syndrome.

DISORDERS OF LATER INFANCY AND CHILDHOOD

Sudden infant death syndrome (SIDS). In developed countries, SIDS (also called crib death or cot death) accounts for 20 percent of deaths between the ages of one month and one year. SIDS is a categorization rather than an explanation, for the label is given when no reason for death can be found from the infant's medical history or even after autopsy.

Most crib deaths occur in the first five months of life and strike at home during the night. They are more common in the winter and in poor social circumstances. A preceding minor respiratory infection is common. This has prompted some investigators to suggest that the underlying defect is the presence of a virus in the bloodstream, leading to instability of cardiac and respiratory mechanisms. Many other hypotheses have been proposed to explain such deaths, however, and it is likely that several different causes may be involved.

Failure to thrive. Failure to thrive is the term used to describe the condition in which a young child fails to gain weight satisfactorily. Common reasons for such poor weight gain are parental neglect or lack of food. On the other hand, a large number of important gastrointestinal disorders may be responsible, including those associated with vomiting, such as food intolerance or obstruction of the upper bowel by pyloric stenosis; disorders of digestion and absorption, including celiac disease and cystic fibrosis; and bowel infections. Alternatively, the body, because of other serious disorders (*e.g.,* chronic infection or heart or kidney disorder), may fail to use the food that is given and absorbed appropriately.

Malnutrition. Malnutrition refers to any disorder brought on by improper diet. In developed countries, the most common form of malnutrition is obesity, the excess accumulation of fat brought on by a diet containing too many calories. Obesity is a major contributor to ill health throughout life. In nonindustrialized nations, by contrast, most malnutrition stems from the lack of food or of particular nutrients. Such deficiency diseases remain an enormous problem. In addition, specific nutritional disturbances are encountered regularly in all populations.

Malnutrition due to inadequate intake of food results in muscle wasting, stunted growth, pallor, increased susceptibility to infection, and fatigue. A special form of malnutrition, in which the intake of calories is adequate but that of protein is not, is referred to as kwashiorkor; it is prevalent in areas of Africa, Asia, and Latin America. Kwashiorkor primarily affects children from six months to five years of age, the onset usually coinciding with the child's being weaned from breast milk (which provides adequate protein) to a diet consisting largely of starchy carbohydrates. The affected children are small, have excess fluid in their tissues, and often have enlarged livers. They have unusual pigmentation of the skin and sparse, reddish hair. Permanent aftereffects of kwashiorkor, especially on the intellectual functions, are matters of great concern.

Kwashiorkor

Vitamin deficiencies can result in a variety of diseases. Rickets is a disorder secondary to deficiency of vitamin D. The major consequence is bone disease, with defective growth of the epiphyseal cartilage. (This cartilage, present in several bones, especially near the ends of the long bones of the arms and legs, ossifies as a person matures.) Scurvy occurs as a consequence of a deficiency of vitamin C. Clinical manifestations include bone disease, irritability, and bleeding under the skin and mucous membranes. Pellagra is due to a deficiency of niacin and is manifested clinically by diarrhea, dermatitis, and dementia. Riboflavin deficiency results in lesions of the skin and corners of the mouth, with a peculiar smoothing of the tongue. Beriberi is a consequence of thiamine deficiency. The major clinical features often relate to cardiac impairment. Defects in the functioning of the nervous system also are common. Deficiency of vitamin A results in ocular abnormalities, growth retardation, anemia, and dermatitis.

Classic infectious diseases of childhood. All of the various types of infectious disease, which can involve virtually every organ and every part of the body, are encountered in children. There are, however, certain infectious illnesses that have become almost synonymous with the term childhood disease. These diseases occur chiefly among children, and one bout usually provides lifelong immunity against further attacks. Such classic infectious diseases of childhood include the exanthematous viral infections (*i.e.,* measles, chicken pox, German measles, and other viral infections that produce skin eruptions) and mumps. The incidence of these diseases, which were once endemic among childhood populations throughout much of the world, now varies markedly. Smallpox, the most serious of the exanthematous viral diseases, has been eradicated worldwide through immunization programs. Other classic childhood disorders—including measles, German measles, and mumps—have been all but eradicated via immunization in countries with high standards of medical care. They remain endemic, however, in areas with poorer health-care systems.

Measles (rubeola) is a viral disease transmitted by the respiratory route, with an incubation period of 10 to 14 days. The initial symptoms include a runny nose, conjunctivitis (inflammation of the membrane lining the eyelids and covering part of the front of the eye), cough, and a characteristic eruption on the mucous membranes of the mouth (Koplik spots). The characteristic rash then appears on the skin, usually beginning over the neck and the face, and spreads to the rest of the body. Recovery is the rule, although serious neurologic complications and secondary bacterial infections of the lungs may occur. Measles ranks as an important cause of death among undernourished children in poor countries, but it rarely causes death or permanent disability in developed countries.

Measles

German measles, or rubella, is a milder disease, also viral, with an incubation period of 14 to 21 days. As discussed earlier, its major significance is the likelihood of its causing severe malformations of the fetus if contracted by the mother during the first three months of pregnancy.

Chicken pox (varicella) is a highly contagious viral disease with an incubation period of 13 to 17 days. At the start there is mild to moderate fever, followed by a generalized eruption of papules, small, solid elevations that appear in crops, initially small and red, becoming vesicular (*i.e.,* becoming small blisters). After several days, no new lesions develop, and the vesicles gradually crust over and heal. Severe itching usually accompanies the rash.

Mumps is a viral disease of the parotid and other salivary

glands, which has an incubation period of 14 to 24 days. The predominant feature of the disease is painful swelling of the parotid glands, which are below and in front of the ears. The pancreas and gonads (sex glands) may also be involved, although rarely in children.

Respiratory disorders. The common cold, or acute nasopharyngitis, the most common respiratory disease in children, is caused by a large number of viruses and may be complicated by superimposed bacterial infection. There is no specific treatment.

Tonsillitis (acute infection of the tonsils) is more properly considered a part of the acute-pharyngitis (throat-inflammation) syndrome. Enlargement of the tonsils as a result of recurrent infection often leads to the decision to remove the tonsils, a course many physicians now believe is rarely indicated. Enlarged tonsils do not cause irritability, poor appetite, or poor growth.

Enlargement of the adenoids (lymphoid tissue in the nasal part of the pharynx) as a result of recurrent infection can result in mouth breathing and a so-called adenoidal facial appearance, the most conspicuous feature of which is the constantly open mouth. By blocking the eustachian tube, it can contribute to infections of the middle ear (otitis media) and to hearing loss. In children with chronic middle-ear disease and a specific type of hearing loss, removal of adenoids may be indicated.

Croup

Croup is an inflammatory disease of the larynx (voice box) or epiglottis (the plate of cartilage that shuts off the entrance into the larynx during the process of swallowing), most often caused by viral infection; it is encountered in infants and small children. Inflammation and swelling of the vocal cords lead to respiratory obstruction, particularly in the inspiratory phase, and a croupy cough, which sounds like the bark of a seal.

Allergic rhinitis (inflammation of the nasal passages) is the most common allergic disorder of childhood. Seasonal allergic rhinitis, or hay fever, due to sensitization to house dust, pollen, or molds, is characterized by attacks of sneezing, nasal itching, and a watery nasal discharge during the season when the specific allergens are prevalent. Similar symptoms are present in perennial allergic rhinitis but without seasonal pattern. In addition to inhalants, sensitization to specific foods may underlie the disorder. Treatment consists of avoidance of the substances causing the reaction, desensitization, and use of decongestant drugs and antihistamines (drugs that, by inactivating the histamine given off by injured cells, suppress many of the symptoms of an allergic attack).

Asthma

Asthma is a common allergic disorder of children that affects the bronchi and bronchioles (the large and small air passages in the lungs). Spasm, edema, and abnormal secretion of mucus result in obstruction of the lower respiratory tract and characteristic wheezing and laboured breathing. Inhalant allergens, particularly dust, molds, and pollens, and foods may play important causal roles. Psychologic stress may be a precipitating factor, but viral or bacterial infection of the respiratory tract is a more common triggering factor. A variety of effective treatments is available, together with preventive measures that reduce the chances of recurrent attacks. The outlook generally is good, with only a small percentage of children continuing to have severe asthma into adult life.

In discussing childhood respiratory diseases, tuberculosis and cystic fibrosis should be included. Both of these disorders predominantly affect the lungs, although many other organs may also be involved. Tuberculosis continues to be a major world health problem. As countries improve public-health standards and increase their socioeconomic level, the illness and mortality from this disease decrease steadily. Tuberculosis appears mostly in a primary form consisting of a small localized lesion of the lung that either heals completely or remains quiescent for many years. Only infrequently among children does the disease extend to involve other parts of the lung or other parts of the body, such as bones, kidneys, or the central nervous system. Miliary tuberculosis, a generalized form of infection, and tuberculous meningitis are the most severe forms of the disease and have an extremely high mortality, although recovery may occur with proper treatment. These forms most commonly occur in young children. As with other diseases, tuberculosis is better prevented than treated. A form of immunization (BCG—bacille Calmette–Guérin—vaccine) is utilized in areas of the world in which the disease is endemic. In other areas, control depends on prevention of contacts and early identification and treatment, if necessary, of infected individuals. A variety of antibiotic agents is effective in treatment, particularly the drugs isoniazid and rifampin.

Cystic fibrosis is a hereditary disorder of the exocrine glands (*i.e.,* those glands that release secretions through ducts). It affects many organ systems, but the lungs suffer most severely. Estimates of incidence vary from one in 3,700 to one in 1,000 live births. It is rare among blacks and Orientals and is transmitted as a recessive trait. The underlying metabolic defect is unknown, but the disease appears to start with the secretion of unusually thick and sticky mucus. In fetuses, intestinal obstruction may result from the production of viscid meconium. Pulmonary involvement may be apparent in the newborn or may develop during childhood, with repeated bouts of atelectasis (collapse of the lungs) and ultimate bronchiectasis (chronic dilation and degeneration of bronchi and bronchioles). Pancreatic insufficiency leads to a malabsorption syndrome, with fatty, bulky stools and malnutrition. The liver may be involved. Abnormality of the sweat glands is evidenced by a high salt content of the sweat, which, in hot weather, may lead to salt depletion and collapse. Treatment is directed toward the many organs involved, particularly with regard to aggressive therapy for respiratory tract infections. Regulation of diet and administration of pancreatic enzymes contribute to the maintenance of adequate nutrition. The ultimate outlook is grave, although therapy has been successful in markedly prolonging life. Many affected persons survive into adult life.

Sinusitis, otitis, bronchitis (inflammation of the sinuses, the ears, and the bronchi, respectively), and pneumonia occur commonly in children and do not differ in essential detail from the same diseases in adults. Other conditions that affect children and adults alike are described in RESPIRATION AND RESPIRATORY SYSTEMS: *Respiratory system diseases.*

Cardiovascular disorders. Congenital heart defects, treated earlier in this article, rank among the most common sources of cardiovascular difficulties in children. Among acquired heart diseases in children, rheumatic fever is the most important cause worldwide, although it has become far less common and less severe in developed countries. Rheumatic fever strikes mainly between the ages of five and 15, occurring as an abnormal reaction to a beta-hemolytic streptococcal throat infection of a few weeks previous. Heart involvement may not be apparent early, but 60 percent of the victims develop rheumatic heart disease in later life; mitral stenosis (narrowing of the mitral valve) is a particularly common complication.

Most disorders of cardiac rate and rhythm in childhood are benign. An exception is paroxysmal atrial tachycardia, a disorder characterized by a steady, rapid heart rate, which in infants may exceed 300 beats per minute. If the disorder persists, it may lead to heart failure. Treatment with digitalis usually restores normal rhythm.

Pericarditis and myocarditis, inflammation of the sac enclosing the heart and of the heart muscle, are caused by a variety of infectious agents; they may result from systemic diseases. The most common cause is acute rheumatic fever. Symptoms include pain, fever, and evidence of heart failure. Treatment and prospects of recovery depend on the underlying cause.

Bacterial endocarditis (bacterial infection of the heart lining) occurs most frequently in children with preexisting heart disease. The most common organism is the alpha streptococcus, which accounts for 80 percent of cases. Common symptoms are fever, a sense of ill health, and fatigue. The outlook depends on the sensitivity of the infecting organism to antibiotic drugs, the age of the affected child, and the type of underlying heart disease.

Blood disorders. Virtually all of the recognized blood diseases of adults are encountered in children. Of particular importance are the conditions in which abnormal types

of hemoglobin are formed. The abnormal hemoglobin present in sickle-cell anemia, also called sickle-cell disease and sicklemia, must be inherited from both parents to cause the disease, the effects of which include hemolytic anemia (anemia involving destruction of red blood cells and release of their hemoglobin) and recurrent crises with episodes of painful swelling of the hands and feet, abdominal pain, and increase of the anemia. Persons who have inherited the defect from one parent and are said to have the sickle-cell trait constitute approximately 10 percent of the U.S. black population. There are a number of other abnormal hemoglobins. Thalassemia, or Cooley's anemia, is a condition in which there is severe, progressive hemolytic anemia, beginning at about six months of age. Like sickle-cell anemia, thalassemia is a recessive hereditary disorder and thus must be inherited from both parents. It occurs in a broad equatorial belt extending from the Mediterranean countries through India to the Far East. Its underlying defect is the deficient production of adult hemoglobin (hemoglobin A). Repeated transfusion of blood and, in certain instances, removal of the spleen are the only available treatments.

Hereditary spherocytosis and hereditary elliptocytosis cause hemolytic anemia because of abnormalities in the structure of the red blood cell. A number of abnormalities in red-blood-cell enzymes also can lead to increased red-cell destruction.

The most common form of anemia in infants and children is caused by iron deficiency. Fetal stores of iron usually prevent development of anemia during the first six months of life, but it is common thereafter, when the diet may not be adequate to meet the high requirements for iron. Apart from pallor, children usually are well, although they may show irritability and lack of appetite. Treatment consists of the administration of iron and modification of the diet to include sufficient iron to prevent recurrence.

Leukemia

Leukemia is a neoplastic (cancerous) disorder of the leukocyte precursors (*i.e.,* young forms) of the white blood cells in the blood-forming tissues. The incidence in childhood is about four cases per 100,000 population. It is the most common malignant disease of children, with a peak onset between two and four years of age. Most cases are of the lymphoblastic type. (Lymphoblasts are precursors of lymphocytes.) Clinical manifestations include anemia, thrombocytopenia (deficit of blood platelets), and infiltration of various organs of the body with leukemic cells. A number of drugs are available for the treatment of leukemia. Remission (disappearance of symptoms) can be induced in about 90 percent of children with acute lymphoblastic leukemia, and half of these survive more than five years.

Thrombocytopenia is a disorder characterized by a tendency toward bleeding because of a decrease in circulating platelets. (The platelets help to stop bleeding in two ways: they contain a clotting factor, and they serve to block rents in blood-vessel walls.) The causes of most cases remain unknown. Treatment consists of replacement of blood when there is a major hemorrhage, transfusion of platelets for emergency management, and, in selected cases, administration of adrenocortical steroids and removal of the spleen. Spontaneous recovery occurs in 80 to 90 percent of cases within three months from onset.

Congenital disorders of the coagulation process usually become manifest during infancy or early childhood. The most common of these is hemophilia, a disease caused by deficiency in a specific coagulation factor. The disease is manifested only in males who have inherited the trait from their mother and occurs in about one of every 10,000 male births. Treatment consists of intravenous injection of the deficient factor, along with measures to control bleeding locally and transfusion of blood when necessary.

Gastrointestinal and liver disorders. Abdominal pain, one of the most common symptoms of childhood, can be indicative of many gastrointestinal disorders but usually occurs without evidence of disease. Recurrent abdominal pain without detectable disease may be a psychosomatic disorder. See also DIGESTION AND DIGESTIVE SYSTEMS: *Digestive system diseases.*

Acute appendicitis occurs in all age groups, although it is rare in extremely young infants. The clinical manifestations (abdominal pain, vomiting, fever) in older children are similar to those in adults. In infants and younger children, the systemic manifestations are more severe, and rupture of the appendix is more frequent.

Intussusception

Intussusception is a condition encountered in the first and second years of life in which one section of intestine doubles (invaginates) into the section next distant from the stomach. Gastrointestinal bleeding and symptoms of obstruction result. Sometimes the intussusception is eliminated by administration of a barium enema. Surgical correction is more usually required, however.

Young children often put things in their mouths, and sometimes they accidentally swallow them. Foreign bodies lodged in the esophagus must be removed. Objects small enough to pass through the esophagus into the stomach usually will pass through the entire intestinal tract, and no treatment is necessary.

Food intolerance is an important cause of vomiting, diarrhea, and failure to thrive in early life. Sometimes the intolerance to a specific food item is temporary, so all that is required is avoidance of that substance for a few months. Other intolerances are more serious and may require lifelong avoidance. Celiac disease is caused by a peculiar sensitivity to the gluten fraction of wheat, rye, or other cereals; therefore, symptoms develop after the introduction of cereals into the diet. Affected children characteristically pass large, bulky, greasy stools; have poor appetite; and are generally miserable. Although they are thin, there may be marked gaseous abdominal distension. The diagnosis is usually made by a biopsy of the affected segment of the intestine (the jejunum). Treatment, consisting of exclusion of gluten from the diet, has a dramatic effect within a few weeks. The patient needs to remain on the special diet throughout childhood and probably should continue it throughout life.

Intolerance to particular sugars may be associated with gluten sensitivity or may occur on its own. The disaccharide sugars—for example, sucrose (table sugar) or lactose (milk sugar)—are the most common offenders. Inability of the intestine to handle these sugars in the normal way leads to diarrhea, malabsorption, and failure to thrive. Fortunately, sugar intolerance is generally a transient event.

Types of viral hepatitis

Viral hepatitis (inflammation of the liver due to infection with a virus) has its highest incidence but lowest mortality rates among children of school age. Two main forms of the disease, hepatitis A and hepatitis B, occur in children. These two forms were distinguished initially by their clinical characteristics and are now recognized to be caused by two different viruses. Hepatitis A (infectious hepatitis) is highly contagious and can be passed from person to person directly, as well as being acquired from contaminated water or food. It is particularly common in communities with poor sanitation. Hepatitis A has an incubation period of 14 to 40 days and usually has an abrupt onset. Fever, headache, and feelings of ill health are followed by loss of appetite, nausea, and vomiting. Jaundice ensues, and the liver becomes enlarged and tender. Improvement is usually noted in a few weeks. In children, complete recovery is common.

Hepatitis B (serum hepatitis) is acquired as a result of receiving blood or blood products from someone who is a carrier of the disease. Thus, it may be acquired from a blood transfusion or from being inoculated with a contaminated needle used by another person (*e.g.,* among drug addicts using the same needle). It has a much longer incubation period (60 to 160 days) and more gradual onset than does hepatitis A. The clinical symptoms are much the same as in hepatitis A, and the outlook for recovery is good in children.

Kidney and urinary-tract disorders. Infection of the urinary tract is common and occurs predominantly in females. The most frequent infection is cystitis, a superficial infection of the lining of the bladder, but pyelonephritis, infection of the kidney, is not uncommon. *Escherichia coli* is the organism responsible in 80 percent of the cases. Symptoms of cystitis include urgency, frequency, painful urination, and suprapubic pain (pain just above the frontal pelvic bones). Pyelonephritis may be without

Cystitis and pyelonephritis

symptoms or may cause fever, back pain, and shaking chills. The patient, who should drink plenty of fluids and void frequently, usually receives antibiotics, which clear the infection rapidly. Ultrasound or X-ray investigation for underlying congenital abnormalities is especially important in young children. Infection recurs in up to 50 percent of cases.

The presence of bacteria in the urine without manifestation of symptoms (asymptomatic bacteriuria) is found in about 1 percent of schoolgirls. This condition is associated with an increased frequency of minor voiding disturbances, of urinary-tract abnormalities, and of symptomatic urinary infections in later life.

Various forms of glomerulonephritis (kidney disease in which there is inflammation of the glomeruli—the knots of minute blood vessels in the capsules of the nephrons, the functioning units of the kidneys) affect children. The type most commonly encountered in children worldwide—though infrequently seen in developed countries—is acute post-streptococcal nephritis. This disorder occurs as a late complication of infection with certain strains of group A beta streptococci. The onset is heralded with blood in the urine, excess fluid in the tissues, or headache due to high blood pressure. Spontaneous recovery ordinarily occurs. A rare patient with unusually severe disease may suffer irreversible kidney damage.

The nephrotic syndrome is a group of symptoms that occurs as a consequence of any kidney disease; characteristically, there is excretion of great amounts of protein in the urine, and generalized edema occurs in the absence of evidence of glomerulonephritis or systemic disease. Most of these children respond to treatment with adrenocortical steroids and ultimately recover. As previously mentioned, congenital nephrosis is an especially severe form that may be apparent at the time of birth. There is no effective treatment, and infants do not usually survive beyond the first year of life.

All forms of glomerulonephritis described in adults are seen also in children. If sufficient information is available, most instances of hereditary nephritis can be shown to have their onset in childhood.

Disorders of specific tubular functions (*i.e.,* functioning of the nephrons) are rare. Nephrogenic diabetes insipidus is a disease of male infants in which there is failure of the kidneys to respond to antidiuretic hormone, with consequent inability to concentrate urine. The symptoms are polyuria (copious urine), polydipsia (excessive thirst), and chronic dehydration. The Fanconi syndrome is a group of diseases in which there are multiple abnormalities in renal-tubular function. In one of these, cystinosis, there is progressive impairment in renal function.

Dialysis and kidney transplant

Children with renal failure and uremia (nitrogenous wastes in the blood) can be treated with dialysis and renal transplant. The major role of dialysis in children is to support patients until a transplant can be performed. Transplant of a kidney from a living, related donor yields the best results, but many children have had successful transplants of kidneys from cadavers (see TRANSPLANTS, ORGAN AND TISSUE).

Nervous-system disorders. Congenital anomalies of the nervous system are common and have been discussed earlier in this article.

Mental retardation is a major problem, affecting about 0.5 percent of young children. For the majority the cause is unknown. Fortunately, most retarded children have only a mild handicap, with an intelligence quotient (IQ) between 50 and 75, and are, therefore, educable and trainable to a reasonable degree of independence as adults. Up to 15 percent of affected children have a more severe handicap, however, and cannot be expected to be independent as adults.

Cerebral palsy refers to a condition in which there is a nonprogressive lesion of the brain causing impairment of movement and posture. Unfortunately, its causes are sometimes responsible for brain or nerve damage in other areas and for mental handicap; these additional problems tend to influence most strongly the quality of the child's life. For children with cerebral palsy, the brain damage is permanent, but it does not increase. Much rarer are the degenerative diseases of the nervous system, most of which are of unknown cause and are untreatable.

Brain tumours are the second most common malignancy of childhood (after leukemia); they are, nevertheless, very rare. The most common brain tumours are situated at the base of the brain and are associated with raised intracranial pressure, causing head enlargement or pain and vomiting. Scanning by computerized axial tomography, which provides a cross-section image of the brain, helps with the diagnosis. A combination of radiotherapy and surgery may be successful in treating such tumours.

Convulsive disorders

Convulsive disorders in children are common. As many as 5 percent of children have a seizure at least once during their lifetime. So-called febrile seizures occur in association with high fever. They are most common between six months and four years of age, and there is a high familial incidence. Spontaneous recovery is usual. Epilepsy, or recurrent seizures, has a prevalence of about 0.5 percent. There are many known causes, but in most cases none is found. Treatment with anticonvulsant drugs is successful in suppressing seizures in most cases.

Eighty percent of all cases of meningitis occur in the first five years of life, and the majority of these strike during the first two years. In most cases, meningitis results from a bacterial or viral infection of the cerebrospinal fluid. Bacterial meningitis is a serious acute illness, in that the bacterial infection may damage the brain permanently. By contrast, most of the common viral causes—including the mumps virus—rarely produce serious illness. Poliomyelitis, however, is a serious form of viral meningitis because of the risk of permanent paralysis. Fortunately, poliomyelitis is rarely seen in countries that provide mass immunization against the disease. The diagnosis of meningitis is made by analyzing a sample of cerebrospinal fluid withdrawn by needle from the spinal canal (*i.e.,* by lumbar puncture). Effective antibiotic therapy is available for the bacterial forms.

Endocrine disorders. In addition to the congenital disorders discussed earlier, a variety of endocrine diseases can occur during childhood. These include precocious puberty, hyperthyroidism, pituitary or adrenal insufficiency, and diabetes mellitus.

Precocious puberty includes a large group of conditions in which there is premature onset of sexual development. Although precocious puberty can result from disease of the brain, adrenals, or gonads, in most instances no underlying disease can be detected.

Overactivity of thyroid function, or hyperthyroidism, is uncommon. Affected children exhibit nervousness, weight loss, irritability, and hyperactivity. Usually there is enlargement of the thyroid gland. A variety of drugs that suppress thyroid function is available. In some instances, surgical removal of most of the thyroid gland is indicated.

General pituitary or adrenal insufficiency results in deficiencies of many hormones and produces a complex disturbance of many body functions, usually requiring urgent treatment. Therapy consists of administration of those hormones that are not being produced in sufficient quantity. A deficiency of the pituitary secretion growth hormone may exist without other deficiencies, in which case it causes merely extreme shortness, the child being otherwise well. Once the condition has been identified by serial measurements of the rate of growth and by measurement of growth hormone in the blood, injections of growth hormone can restore the child to normal height.

Diabetes mellitus in childhood is nearly always of the type 1 variety; *i.e.,* resulting from a deficiency of the pancreatic hormone insulin. Because there is a familial tendency for the condition, and because more children have been treated and have grown up to have their own children, there has been an increased incidence of diabetes worldwide. The most striking clinical features, elevated levels of glucose in the blood and increased excretion of glucose in the urine, are due to the patient's inability to metabolize glucose normally. Abnormalities in fat and protein metabolism are also present. Control of the abnormal handling of glucose by the daily administration of insulin and some restrictions of diet can keep most children asymptomatic and enable them to lead normal,

healthy lives. Even the best control, however, might not prevent vascular and neurologic complications that occur 20 or more years later. The outcome, therefore, is unsure, and the majority of persons with onset of diabetes mellitus in childhood appear to develop significant complications in adult life and to have a reduced life expectancy.

Skin disorders. Skin disorders are common during childhood. Birthmarks and diaper rashes (both considered above), eczema, and local infections are often seen.

Eczema is characterized by reddening of the skin, papules, oozing, and crusting with intense itching. In infants the lesions often appear first on the cheeks and then develop on other areas, while older children are most affected on the insides of the elbows and the knees. Treatment includes attention to any underlying allergic causes and local application of a variety of different medications, especially adrenocortical-steroid ointments.

Impetigo contagiosa is a superficial infection of the skin with *Staphylococcus aureus* or hemolytic streptococci. Vesicular or pustular lesions exude moisture and become crusted. Untreated, the lesions tend to become widespread and may involve any area of the skin or the scalp. Treatment consists of keeping the affected areas clean and local or systemic administration of antibiotics.

Fungal infections of the skin are also common. Thrush, a disease characterized by small, white spots in the mouth or a diffuse rash on the body, affects infants infected by the fungus *Candida albicans*. In the older child, tinea capitis (ringworm of the scalp), tinea corporis (ringworm of the body), and tinea pedis (athlete's foot) are all common superficial fungal infections.

Warts, also called verrucae, are the most common viral skin infection and are probably more common in childhood than at any other time. The average life of a wart is three to four months, so treatment is usually reserved for long-lasting warts. On the sole of the foot a verruca that becomes rather flattened is called a plantar wart.

Various parasites may cause skin infestations. The common head louse (*Pediculus humanus capitis*) causes irritation of the scalp and lays tiny, whitish eggs (nits) on the hair. Head lice are easily eradicated by the application of special lotions to the scalp of the child (and the rest of the family). Scabies is an infection caused by the itch mite (*Sarcoptes scabici*), which lays its eggs in burrows beneath the skin. After a few weeks of infestation, the child becomes sensitized to the parasite and develops an itchy rash, particularly on the hands and armpits. The infestation is transferred by bodily contact, so that other family members are commonly infected, and all should be treated with creams or lotions that eradicate the mite.

Connective-tissue disorders. Henoch-Schönlein purpura (anaphylactoid purpura) is the most common connective-tissue disorder in children. It is characterized by a purpuric rash, painful swollen joints, and abdominal pain with vomiting. In a minority of patients, the kidneys become involved and nephritis develops; this is the only complication that may cause permanent damage. In general there is complete recovery.

Juvenile rheumatoid arthritis, or Still's disease, is rare. In very young children it is characterized by general illness, fever, and rashes, with comparatively mild joint involvement. In older children, the adult pattern of the illness is seen, with predominant joint involvement and little or no general illness. More than half of affected children make a complete recovery; the rest have recurrences requiring treatment.

Accidents. In developed countries, accidents cause more loss of life and disability among children (except infants) than any disease. Road-traffic mishaps account for nearly half of the accidental deaths—usually the child involved being a pedestrian or cyclist. Accidents in the home, by way of burns and falls, account for another quarter. Boys are more at risk than girls, particularly if they are from a large family living in a poor, inner-city area. Children are more likely to suffer serious burns and scalds than adults because of the fact that their skin is thin and more liable to full-thickness damage.

Poisoning

Accidental poisoning is very common, particularly among two- to four-year-olds, who are inquisitive and use their mouths to feel and taste new objects. Accidental ingestion of household fluids and medicines is common. Fortunately, it is usual for the child to swallow only a tiny amount, and severe illness from such poisoning is rare. Medicinal drugs are much more likely to cause illness than are household and garden products, berries, or toadstools.

Lead poisoning has become less common worldwide, though there is increasing worry about prolonged exposure to low levels of lead and its possible relationship to abnormal childhood behaviour and intelligence. Low-level lead poisoning generally results from unavoidable exposure to atmospheric lead pollutants. This is a problem in some heavily industrialized areas and in those regions where leaded gasoline is still burned in automobiles.

Child abuse and neglect. The spectrum of child abuse is wide. It includes not only children who have suffered physical abuse with fractures and bruises ("the battered child") but also those who have experienced emotional abuse, sexual abuse, deliberate poisoning, and the infliction of fictitious illness on them by their parents (Munchausen syndrome by proxy). Children under the age of two are most liable to suffer direct physical abuse at the hands of their parents. Such abuse is more common in families who are poor and are living under stress and in which the parents themselves suffered cruelty as children. Frequently, the child shows other evidence of poor nutrition or neglect. Most developed countries have a well-established system for dealing with suspected cases of abuse, involving child-protection agencies, social workers, and, if necessary, the police.

Sexual abuse

Sexual abuse, in which dependent, developmentally immature children are involved in sexual activities that they do not fully comprehend and to which they cannot give informed consent, has become increasingly recognized. Girls are involved mainly, and their fathers are the usual offenders. Sexual abuse frequently does not come to light until the older girl develops a psychosomatic illness, runs away from home, or is truant from school.

Psychological disorders. All disorders have both a physical and psychological component. For many disorders—such as asthma, eczema, and ulcerative colitis—the importance of physical and emotional factors varies at different times during the course of the disease. Moreover, the individual's concept of illness and his worries about it inevitably contribute to the severity and duration of a particular illness. A three-year-old may have no concept of disease or of time. Consequently, he may not worry about the cause or duration of a disease but instead be much more upset by immediate discomforts associated with the illness. A young child may view admission to the hospital as particularly frightening and unpleasant. Unless the parents can be with him, he may see their absence as a complete loss and cannot appreciate that he may be back with them and well two days later. Thus, great efforts are made to avoid hospitalizing children. When a youngster is admitted to a hospital, the parents are encouraged to be with him as much as possible and, when conditions permit, to sleep beside the young child in the hospital.

In other ways, the fact that the young child has no concept of illness is an advantage, for as soon as an acute illness is over, the child resumes normal health with startling rapidity—he does not feel in need of convalescence in the way that an adult does after a frightening experience. Children have great and speedy powers of recovery.

Stress precipitates symptoms in people of all ages. Headaches, leg aches, stomachaches, and vomiting are common symptoms of stress in children. The sort of stress that causes such symptoms may be problems at home—such as parental discord, inconsistent parental behaviour, rivalry with siblings, or unrealistic expectations by parents—or problems at school or with friends. The loss of a parent or a move to a new home can be an acute stress.

Minor behaviour disturbance involving enuresis (urinating), soiling (defecating), or sleep disorders are common. Most children who exhibit such behaviours should not be considered psychologically abnormal. Similarly, habit spasms (tics) involving repetitive involuntary movements, usually of the head and neck, are extremely common, affecting up to 10 percent of 10-year-olds.

Severe behaviour disorders are much less common, and true childhood psychosis is most uncommon. Hyperactivity is a behaviour disorder characterized by perpetual overactivity. Hyperactive children refuse to concentrate on one task for long, are always on the go, and need relatively little sleep. They are very easily distracted, and, because of the lack of concentration, school problems arise. The incidence of hyperactivity varies enormously from country to country, and it is likely that local fashions and beliefs greatly affect the criteria for diagnosis. Most young children are very active and exhaust their parents, and few concentrate on their schoolwork as much as their parents wish. Thus, parents often see a child as overactive and readily suggest hyperactivity as the problem, though strict measurement of psychological criteria rarely demonstrates its presence. Enthusiasts embark on behaviour-modification therapy and sometimes drug therapy.

DISORDERS ASSOCIATED WITH ADOLESCENCE

Adolescence begins with the onset of sexual maturation and continues through the transition state from childhood to young adulthood. The beginning is biologically defined by the onset of puberty, usually during the 10th to 13th year. The end is less definable and, depending upon environmental factors, may be as early as 16 years or as late as 20. In addition to rapid anatomical and physiological changes occurring during adolescence, the period is one of rapid psychosocial and psychosexual change, with tremendous turmoil generated over feelings of inadequacy, increase in sexual and aggressive drives, internal disorganization, and the attempt to attain self-control.

During adolescence, body weight almost doubles, and an additional 25 percent in height is gained. Secondary sexual characteristics appear, menstruation begins in girls, spermatogenesis (sperm formation) starts in boys, and fertility is established in both sexes. Adolescents establish a sense of identity and achieve a degree of independence that ultimately prepares them to take their place in adult society. It is expectable, therefore, that the major disorders of adolescence concern problems of growth, sexual development, and psychological disturbances.

Disturbances of growth chiefly concern short stature in boys and tall stature in girls, both conditions being a potential source of psychological handicap. Although organic and genetic causes of short stature in boys must all be considered, most relatively short but otherwise healthy children are simply late maturers. Graphic plots of height gain with age reveal steady, normal progression but a delayed pubertal growth spurt, concordant with the delay in sexual maturation. With further sexual maturation, acceleration in growth will occur, and adult height within normal limits will be achieved. Similarly, many excessively tall adolescent girls are early maturers; with early sexual and skeletal maturation, their linear growth stops at an adult height well within normal limits.

Sexual development

The sequence of sexual development in girls is extremely variable. Widening of the bony pelvis, growth of the nipples and breasts, changes in external and internal genitalia, and the menarche occur sequentially as pituitary gonadotropin (sex-gland-stimulating hormone) causes ovarian release of estrogen (female sex hormone). Axillary (armpit) and pubic hair and some of the changes of the external genitalia develop under the stimulus of androgens of adrenal origin. Since these arise from a different source of pituitary stimulation, there is considerable variation among girls in the relationship of their appearance and, for example, development of the breasts. Recognition of this helps to allay anxieties over "abnormal" sexual development.

Menstruation in adolescence is characterized by many functional disturbances, including oligomenorrhea (scant menstruation), amenorrhea (absent menstruation), menorrhagia (excessive bleeding), and dysmenorrhea (painful menstruation). Amenorrhea requires a thorough evaluation for possible organic abnormality, such as underfunctioning sex glands, absence of the uterus, or obstruction to the menstrual flow. In most instances, skipped menstrual periods during the first year or so after the menarche reflect the common irregularity of menstruation during early adolescence. Later in adolescence, transitory amenorrhea may be associated with stress, such as onset of the school year or moving to a new home. Treatment is not usually required.

Sexual development in boys usually follows a more predictable sequence, although there is great variation in the time of onset of puberty and the time of achievement of full sexual maturation. Stimulation of the testes by pituitary gonadotropins results in the release of the hormone testosterone, which causes growth of the internal and external genitalia, development of pubic, axillary, and facial hair, changes in the larynx that result in deepening of the voice, and increased statural growth and muscular development. In about half of all boys, noticeable swelling of mammary-gland tissue occurs midway through adolescence. When the enlargement of the breasts is great enough to engender concern, it is called gynecomastia. In most instances, the enlargement disappears spontaneously.

Acne vulgaris (common acne) is a prevalent skin condition that has its onset during adolescence. At puberty, androgenic stimulation of the skin's sebaceous (oil) glands (which empty into the canals of the hair follicles) causes increased production of the fatty substance sebum. In susceptible individuals, there is oversecretion of sebum. Sebum and cellular debris then form a plug in the follicle canal, and the growth of bacteria in the plug produces unsightly pustules. Prolonged treatment is often needed.

Psychological disturbances

The psychological disturbances of adolescence are universal and protean, ranging from minor emotional upsets to schizophrenia—from mild feelings of inadequacy to suicide. The sexual and aggressive impulses of the preadolescent period are complicated by the advent of physical and sexual maturity. Both an inability to control urges and desires and an excessive degree of self-control are characteristic. Some adolescents remain too dependent on their parents; others attempt to achieve independence too quickly. As many as 10 percent of adolescents may have psychological disturbances that seriously interfere with their functioning and the development of social relations.

One well-known major psychological disorder that generally begins in adolescence is anorexia nervosa. The onset is usually at puberty. The victims, overwhelmingly girls, at first appear healthy but then refuse to eat, and they lose weight. As they lose weight they begin to look ill, and expert help is required in order to encourage them to eat again and regain health. Anorexia nervosa is rare.

Unfortunately, certain other major behavioral disturbances of adolescence have become increasingly prevalent in the late 20th century. Suicide has become much more common; suicidal gestures are particularly common in girls. In many industrialized countries, suicide ranks as the second or third most common cause of death during adolescence (after accidents and, in some countries, malignancy). Delinquency, vandalism, and dropping out of school have become increasingly widespread and are often associated with addiction to drugs or alcohol.

BIBLIOGRAPHY. BENJAMIN SPOCK and MICHAEL B. ROTHENBERGER, *Baby and Child Care*, new rev. ed. (1985), provides comprehensive coverage of current medical practices and parental concerns. Comprehensive pediatric texts include ABRAHAM M. RUDOLPH, JULIEN I.E. HOFFMAN, and SUSAN AXELROD (eds.), *Pediatrics*, 17th ed. (1982); VICTOR C. Chile

The Republic of Chile (República de Chile), situated on the Pacific coast of South America, is an extremely long and narrow country that extends approximately 2,700 miles (4,300 kilometres) from its boundary with Peru in the tropical zone, at latitude 17°30′ S, to the tip of South America at Cape Horn, latitude 56° S, a point only about 400 miles north of Antarctica. This unusually shaped country has an average mainland width of slightly more than 100 miles, with a maximum of 217 miles at the latitude of Antofagasta and a minimum of 9.6 miles near Puerto Natales. It is bounded in the north by Peru and Bolivia, on its long eastern border by Argentina, and to the west by the Pacific Ocean. Continental Chile and its offshore islands comprise 292,135 square miles (756,626 square kilometres). Chile exercises sovereignty over Easter Island, the Juan Fernández Archipelago, and the volcanic islets of Sala y Gómez, San Félix, and San Ambrosio, all of which are located in the South Pacific. The country also claims a 200-mile offshore limit.

Chile's relief is for the most part mountainous, with the Andes range dominating the landscape. Because of the country's extreme length it has a wide variety of climates, from the coastal desert beginning in the tropical north to the cold subantarctic southern tip. Chile is also a land of extreme natural events: volcanic eruptions, violent earthquakes, and tsunamis originating along major faults of the ocean floor periodically beset the country. Then, too, fierce winter storms and flash floods alternate with severe summer droughts.

Much of northern Chile is desert; the central part of the country is a temperate region where the bulk of the population lives and where the larger cities, including the capital, Santiago, are located; south-central Chile, with a lake and forest region, is temperate, humid, and suitable for grain cultivation; and the southernmost third of the country, cut by deep fjords, is an inhospitable region: cold, wet, windy, and limited in resources. The economy of Chile is based on primary economic activities: agricultural production; copper, iron, and nitrate mining; and the exploitation of sea resources.

Chile exhibits many of the traits that typically characterize Latin-American countries. It was colonized by Spain, and the culture that evolved was largely Spanish; the influence of the original Indian inhabitants is negligible. The people became largely mestizo, a blend of Spanish and Indian bloodlines. The society developed with a small elite controlling most of the land, the wealth, and the political life.

Chile, however, did not depend as heavily on agriculture and mining as did many Latin-American countries, but rather developed an economy based on manufacturing as well. Thus, Chile has become one of the more urbanized Latin-American societies, with a burgeoning middle class. Chile has also had a history of retaining representative democratic government. Except for a military junta that held power from September 1973 to March 1990, the country has managed to stay relatively free of the coups and constitutional suspensions common to many of its neighbours.

This article is divided into the following sections:

Physical and human geography

THE LAND

Relief. The major landforms of Chile are arranged as three parallel north–south units: the Andes mountains to the east; the intermediate depression, or longitudinal valley, in the centre; and the coastal ranges to the west. These landforms extend lengthwise through the five latitudinal geographic regions into which the country is customarily subdivided. From north to south, with approximate boundaries, these are Norte Grande (extending to 27° S); the north-central region, Norte Chico (27° to 33° S); the central region, Zona Central (33° to 38° S); the south-central region, La Frontera and the Lake District (38° to 42° S); and the extreme southern region, Sur (42° S to Cape Horn).

Regions of Chile

The Chilean Andes. Extending almost the length of the country, the Chilean Andes, which form most of the border with Argentina, include the highest segment of the Andes mountain chain, which acts as both a physical and a human divide. The Chilean Andean system consists of lofty, often snow-capped mountains, deeply incised valleys, and steep slopes.

The formation of the western Andes ranges began during the Jurassic Period, some 190,000,000 years ago. Marine and terrestrial sediments that had accumulated in the Andean geosyncline were folded and lifted as the Pacific Plate was overridden by the South American Plate. In the early Tertiary Period (beginning 65,000,000 years ago) active volcanism and the injection of effusive rocks laid down the paleovolcanic materials (rhyolites and dacites) that contain the rich copper, iron, silver, molybdenum, and manganese ores of Chile. Also of Tertiary origin are the coal deposits of central Chile.

Geologic history of the Chilean Andes

Later in the Tertiary Period the uplift of the Andes continued, accompanied by further outbursts of volcanism. This active tectonism led to the separation of the Andes from the older coastal ranges and the formation of the intermediate depression. At the beginning of the Quaternary Period the Andes had reached a higher elevation

than at present. During the global cooling that occurred some 2,500,000 years ago, the higher summits were covered by ice masses whose glacier tongues descended into the intermediate depression. Rich sediments were washed down the glacial valleys and deposited into the longitudinal depression. The numerous lakes in the Lake District of south-central Chile are remnants of the ice melting that began some 17,000 years ago. Since the advent of the Holocene Epoch (beginning 10,000 years ago) the Chilean Andes have not changed significantly, but they still experience uplift and episodic volcanic eruptions.

The Andes of northern Chile to latitude 27° S are wide

Zones of the Chilean Andes

and arid, with heights generally between 16,500 and 19,500 feet (5,000 and 6,000 metres). Most of the higher summits are extinct volcanoes, such as the Llullaillaco, 22,109 feet; Licancábur, 19,409 feet; and Ojos del Salado, 22,614 feet. After the last glaciation the melting waters collected in shallow lakes in the intermediate elevated basins. Today these salt lake basins (*salares*), the most noted of which is the Atacama Salt Flat, are evaporating to the point of disappearing. Farther south the mountains decrease somewhat in height, but in central Chile, between latitudes 32° and 34°30′ S, they heighten again, with peaks reaching 21,555 feet at Mount Tupungato and 17,270 feet at Maipo Volcano. All of these summits are capped by eternal snow that feeds the numerous rivers of central Chile. Winter sports are pursued in the Andes near Santiago.

Most of the highest mountains between 34°30′ and 42° S are volcanoes, ranging between 8,700 and 11,500 feet. Some of them are extinct while others are still active. Among them are Copahue, Llaima, Osorno, and the highest, Mount Tronador, at an elevation of 11,453 feet. Their perfect conical shapes reflecting on the quiet waters in the Lake District provide some of the most splendid scenery in temperate South America. In southern Chile, below latitude 42° S, the Andes lose elevation and their summits become more separated as a consequence of the Quaternary glacial erosion.

Farther south is Chilean Patagonia, a loosely defined area that includes the subregion of Magallanes and sometimes Chilean Tierra del Fuego. There significant heights are still reached: Mount San Valentín is more than 12,000 feet high, and Mount Darwin in Tierra del Fuego reaches almost 8,000 feet. Reminders of the last ice age are the perfectly U-shaped glacial troughs, sharp-edged mountains, Andean lakes, and some 7,000 square miles of continental ice masses. The Southern Ice Cap, between 48°30′ and 51°30′ S, is the largest in the Southern Hemisphere, with the exception of Antarctica.

The intermediate depression. The intermediate depression between the Andes and the coastal ranges is mostly flanked by fault lines. A natural receptacle for materials coming from the Andes, the depression has been filled by

Farmland on Lake Puyehue and, in the right background, Puyehue Volcano, Osorno province, the Lake District.
Chip and Rosa Maria Peterson

alluvial, fluvioglacial, or moraine sediments, depending on the region. In northern Chile it appears as a plateau with elevations between 2,000 and 4,000 feet. Saline sediments that washed down during the Tertiary and Quaternary periods created the rich nitrate deposits found in the Tamarugal Plain and Carmen Salt Flat, where the once-bustling mining towns of María Elena, Pedro de Valdivia, and Baquedano are located. In north-central Chile, extending southward out of the desert region, the depression is interrupted by east–west mountain spurs that create fertile transverse valleys. The Aconcagua River Valley, a transverse valley farther south, marks the beginning of central Chile.

The alluvial deposits from the numerous Andean rivers in central Chile have provided mineral-rich soils that support the flourishing Mediterranean-type agriculture of the Central Valley of the intermediate depression. These soils and abundant water resources, along with a temperate climate, make the Central Valley the most populated and productive area in Chile. In south-central Chile the intermediate depression is formed by mixtures of fluvial and alluvial depositions, making this region suitable for growing grain and for pastures that support an important dairy industry.

The Central Valley

South of the Bío-Bío River dense forests replace open scrub woodland moraines and lakes are common, and the intermediate depression descends to sea level at Puerto Montt. In the extreme south only the Andes and the summits of the coastal ranges are visible because the intermediate depression submerges or is replaced by intracoastal channels and fjords.

The coastal cordilleras. In most of northern and central Chile coastal ranges form a ridge between the intermediate depression and the Pacific coast. These mountains, which are seldom higher than 6,500 feet, display smooth forms or flattened summits, since they are considerably older than the Andes. In north-central and central Chile the coastal ranges are built of Paleozoic and Mesozoic granites and metamorphic rocks that were uplifted during the Andean folding phase. In south-central and southern Chile the coastal ranges consist of early Paleozoic metamorphic and igneous rocks, which is evidence of an even earlier folding phase. The coastal ranges were never glaciated, and their former dense vegetation has been destroyed by humans. In places where intensive agriculture has been practiced, the soil is severely eroded and has been depleted of organic and mineral nutrients. Only in the evergreen forests in the Cordillera de Nahuelbuta south of Concepción and the coastal ranges south of Valdivia are the soils well preserved.

On the western margins of the coastal ranges, sea advances during the Tertiary Period deposited thick sediments. During the Quaternary Period sea level changes and continued continental uplift created several coastal terraces in the Tertiary layers, and wave erosion shaped Chile's abrupt coastal line, which has few good natural harbours.

Drainage. Most of Chile's rivers originate in the Andes and flow westward to the Pacific Ocean, draining the intermediate depression and the coastal ranges. They are therefore quite short. While their steep gradients and turbulent flow make them unsuitable for navigation—the lower courses of the south-central rivers are an exception—they are particularly useful for hydroelectric power. In areas where water flow is subjected to seasonal variations that hamper agricultural development, dams have been built in order to regulate the rivers and to establish hydroelectric plants.

The rivers

The rivers of Chile have differing physical characteristics that are related to the climatic region in which they are located. In the parched northern region they are fed by the summer rains that fall on the Chilean-Bolivian Altiplano; their volumes are so small that they are either absorbed by the soil or evaporate before reaching the sea. Only the Loa River, the longest Chilean river at some 275 miles, empties into the Pacific Ocean.

The rivers of central Chile have more regular flows and volumes. During the winter months (May–August) they are fed by heavy frontal rains, resulting in frequent flooding of the riverine communities. In late spring (October–November) the rivers receive the runoff from the snow that has accumulated during the winter in the high Andes. This runoff proves quite beneficial for commercial and subsistence crop irrigation. In south-central Chile south of the Bío-Bío River, the steady flow is maintained by constant rains, although there is a slack in discharge during the summer months (December–March). In Chilean Patagonia and Tierra del Fuego intense year-round rains and snowstorms combine to keep the rivers well fed, but their extremely steep drainage into the Pacific renders them totally unusable for commercial purposes.

Soils. The geologic variety and diverse origin of surface sediments cause the soils of Chile to vary greatly in character from north to south. In the northern desert region saline soils, made up of gravel and sand cemented with calcium sulfate, alternate with alkali-rich soils, which are difficult to cultivate even with irrigation because of their surface salt accumulations. In river oases salinity also becomes a limiting factor for agriculture. In the transverse valleys of north-central Chile fertile alluvial soils have developed on fluvial deposits, while between the rivers soils are dry and infertile. Within the Central Valley the alluvial soils have developed over fluviovolcanic deposits, which is the reason for their mineral and organic richness. In areas of widespread recent volcanic activity, andosol soils (nutrient-rich soils that develop over volcanic ash)

Rich Central Valley soils

are common. Under good aeration these soils of the Central Valley have excellent agricultural potential, but if the volcanic soils are too permeable, they can be used only for coniferous plantations. In the Lake District the extreme impermeability of the soils leads to the formation of humid soils (*trumaos*). In the southernmost Andes, under conditions of permanent rainfall and cold temperatures, lithosols covered by a thin layer of andosols are the rule: only rain forests grow on such soils. On the archipelagos of Chilean Patagonia and Tierra del Fuego the low terrain is carpeted by moorland soils that support only low shrubs and bog plants of no economic value or potential. Soils at high elevation are characterized by rankers (thin organic soils overlying a rocky substratum) supporting growths of Antarctic beeches.

Climate. The extension of Chile across some 38 degrees of latitude encompasses nearly all climates, with the exception of the humid tropics. The Pacific Ocean, the cold Peru (Humboldt) Current, the South Pacific anticyclone winds, and the Andes Mountains constitute the major climatic controls.

The permanent chilling effect of the Peru Current and the constantly blowing southwesterlies emanating from the South Pacific anticyclone determine a temperate climate for most of northern and central Chile. Only the extreme south, unaffected by these controls, is characterized by a cold and humid climate. Temperatures drop in a regular pattern from north to south; the principal cities average the following annual mean temperatures: Arica 64° F (18° C), Antofagasta 61° F (16° C), Santiago 57° F (14° C), Puerto Montt 52° F (11° C), and Punta Arenas 43° F (6° C). During winter, when the polar front advances northward, temperatures drop, though not drastically, owing to the temperate action of the ocean. If snow falls in central Chile, it does not stay on the ground for more than a few hours. During summer, cooling sea winds keep temperatures down and there are no heat waves. The highest monthly means register in the northern desert.

Temperatures of key cities

Annual precipitation differs remarkably from the dry extreme north to the very humid extreme south. North of 27° S latitude there is practically no rainfall. In the north-central region frontal rains in winter account for increasing precipitation: the annual rainfall in Copiapó is less than one inch (21 millimetres). In Santiago the annual rainfall is 13 inches, and along the Central Valley it increases gradually southward until it reaches 73 inches in Puerto Montt, where precipitation occurs throughout the year. The coast of central and south-central Chile is more humid than the Central Valley. In Valparaíso annual precipitation amounts to 15 inches, rising to 52 inches in Concepción and reaching about 90 inches in Valdivia. Farther south, where the westerlies reach their maximum intensity and the polar front is always present, precipitation highs unequaled by any other nontropical region in the world have been recorded; there, San Pedro Point, at latitude 48° S, receives about 160 inches annually. Still farther south, in the rain shadow that occurs on the eastern slopes of the southern Andes, precipitation diminishes drastically, occurring mostly as snow during winter. Punta Arenas, in Chilean Patagonia, receives only 18 inches annually.

Considering all climatic factors and meteorological characteristics, three large climatic regions may be distinguished in Chile: the northern desert, the central Mediterranean zone, and the humid-cool southern region.

Climatic regions

The northern desert. This region experiences an aridity that is primarily caused by the dry subsidence created by the South Pacific high pressure cell and the stabilizing action of the cold Peru Current. Although the air along the coast is abnormally humid, it never reaches saturation point; at most, there is a development of coastal fogs (*garúa* or *camanchaca*). Besides the lack of rain, drainage systems, and permanent vegetation, the Chilean desert is characterized by relatively moderate daytime temperatures, the variations in which are dependent upon the direct heat of the Sun; during the night, temperatures may approach the freezing point. In the piedmont oasis of Los Canchones the daily temperature fluctuates up to 47° F (26° C). The interior of the Atacama Desert, which makes up a large portion of the southern part of the desert region, is reported to receive the highest solar radiation in the world.

Mediterranean central Chile. The climate of central Chile is characteristic of mid-latitudinal temperate areas. The seasons are well accentuated. Winters are cool and humid as a consequence of continuous passages of fronts and depressions; cloudy days are common. In spring, when there are fewer fronts and the depressions vanish, steady southwest winds and clear skies dominate. During summer, when anticyclonic conditions are established, the days are warm, though not stifling, and without rain. These weather conditions are ideal for the Mediterranean agricultural products that grow so well in central Chile, such as grapes, peaches, plums, honeydew melons, and apricots. Autumn is still sunny and dry, suitable for the ripening of grains, mainly wheat, and vegetables. With the onset of winter, the fronts and depressions return and the accompanying rains last from May to August.

Southern Chile. The southern segments of Chile are always under the influence of the polar front and of cyclonic depressions. In addition, the permanently blowing westerlies batter the margins of the continent with oceanic air masses that lower temperatures and cause heavy rainfall along the Pacific coast. Around Cape Horn the westerlies reach their maximum intensity and storms abound. Before the era of steam power, the passage from the Atlantic to the Pacific via Cape Horn was a most feared venture.

Plant and animal life. The vegetation of Chile, like the climate and soils, is arranged in latitudinal belts. Only in the Andes is altitude a determining factor. In the northern desert region the vegetation has adapted to the lack of rain and to the salinity of the soils. The tamarugo, a spiny acacia tree, does well in the dry interior desert. Near the coast, and kept alive by the coastal fogs, varieties of cacti as well as shrubs and spiny brambles occur. In the high plateaus of northern Chile hardy species, such as llareta, and grasses, such as ichu and tola, support the Indian population and their llama herds. In semiarid north-central Chile some of the cacti continue, and hardwoods, such as the espino or algarrobo, and shrubs, such as *Adesmia,* become more common. In the more humid and temperate region of central Chile grows a particular vegetal formation called *matorral,* in which hardwoods, shrubs, cacti, and green grass are mixed. Most of this dense growth is disappearing because of the rural population's overexploitation of it for firewood. South of the Bío-Bío River, mixed deciduous forest and evergreen trees are common. Many unique species are found in these humid forests, the most conspicuous being the rauli, or southern cedar, the roble beech, the ulmo (an evergreen shrub), and the evergreen laurel. On the western slopes of the Andes the magnificent monkey puzzle tree, or Chile pine, forms dense stands. A dense rain forest, rich in timber species, grows in the humid Lake District and extends southward. The Antarctic beech, the Chilean cedar, and the giant alerce dominate these often impenetrable southern woods. On the rainy islands of Chilean Patagonia and Tierra del Fuego, the growth of large trees is inhibited by the constant winds and low temperatures. There, only dwarf versions of southern beech and hard grasses are found. In eastern Chilean Patagonia the cold steppes are primarily composed of grasses and herbs that provide grazing for livestock.

Unique trees of the humid forests

The animal life of Chile lacks the diversity of other countries in South America. The barrier of the Andes has restricted animal migrations, and the northern desert has proved a formidable obstacle to the southward migration of tropical Andean fauna. Among the terrestrial animals, the most abundant and varied are the rodents. The chinchilla, the degu, and the mountain viscacha are Andean rodents famed for their fine furs. *Monito de monte,* a marsupial, lives in the deciduous forests and rain forests of the south. The nutria, or coypu (*coipo*) is a water rodent common in the streams of Chile. Among the ruminants are the guanaco, the only survivor of the Paleocamelides (ancient predecessors of the camel family), and its domesticated relatives, the llama, the alpaca, and the vicuña, the latter known for the high-quality wool produced from its

silky fleece; the Indians of the Altiplano make wide use of it. Guanacos are still found from northern Chile to Chilean Patagonia. Two members of the deer family are the huemul, a rarely seen inhabitant of the southern Andes that is represented on the national coat of arms, and the pudu, the smallest known deer. Carnivores are not in great abundance. The puma is the largest, and other feline predators include the *guiña* and the *colocolo*. Among the canids are the Andean wolf and the long-tailed fox. The avian fauna is relatively more diverse, the country being host to wintering migratory birds. Some exotic birds like parrots and flamingos appear over northern and central Chile. Throughout the Chilean Andes there still lives, though reduced in number, the condor, a large scavenger. In Chilean Patagonia is found the carancha, a bird of prey that attacks lambs. Amphibians abound, the most curious being Darwin's frog, discovered by Charles Darwin in south-central Chile. Chile's geographic isolation accounts for the absence of poisonous reptiles and spiders.

Exotic bird life

Settlement patterns. Climatic characteristics and historic events have strongly influenced settlement patterns and population distribution in contemporary Chile.

The early settlement by Spaniards occurred in the temperate part of the country, known as the Central Nucleus, or Zona Central, where the agriculture, industry, and main population centres developed. The area's traditional agriculture developed on the basis of large landed estates, the haciendas, which covered about three-quarters of Chile's arable land. The agrarian reform initiated by the Christian Democratic president Eduardo Frei Montalva in 1965, and continued by the Socialist president Salvador Allende Gossens into the early 1970s, resulted in a redistribution of the land. Agrarian productivity to boost exports was accentuated.

The Central Nucleus

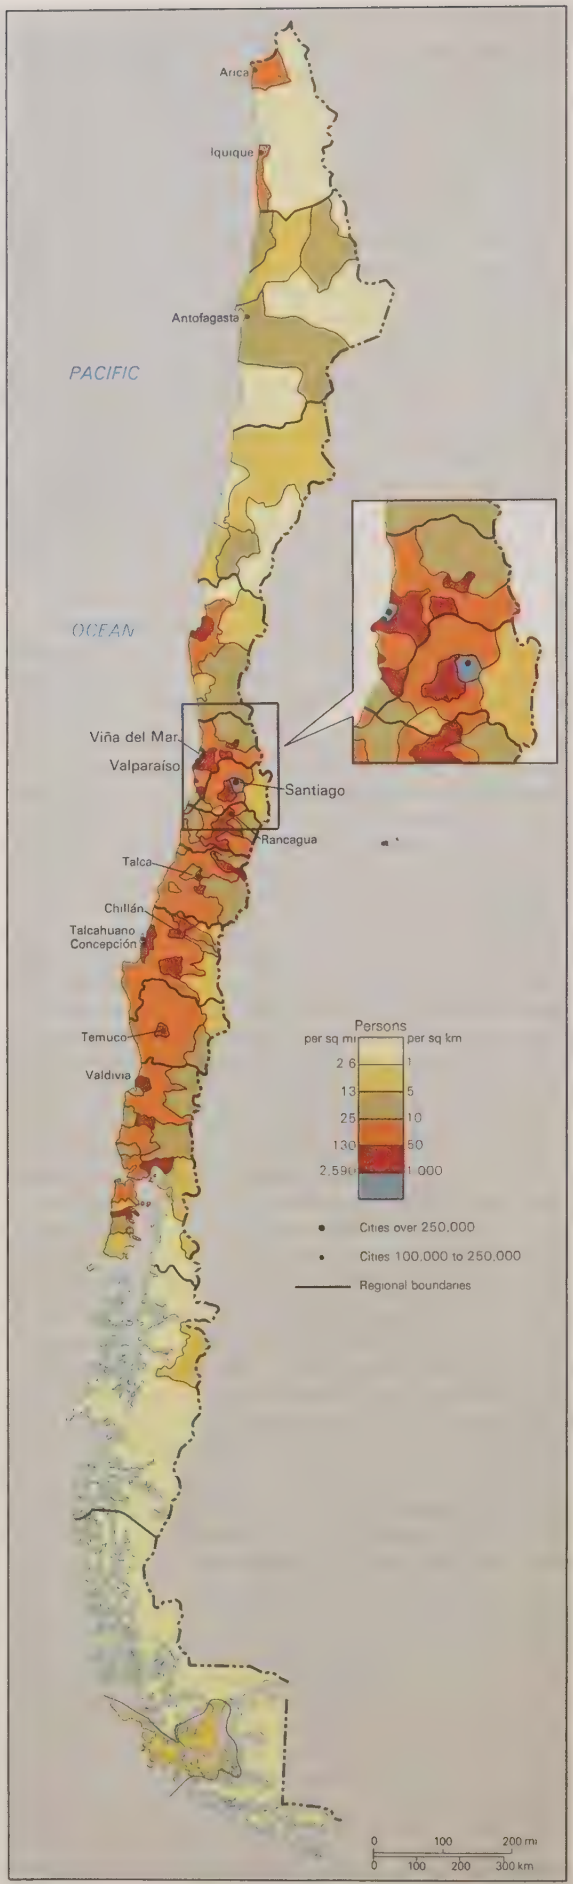
In the Central Nucleus are the major cities of Chile. Santiago was founded there and grew into the country's major metropolis. Seventy miles west of Santiago is the port city of Valparaíso and the neighbouring resort city of Viña del Mar, which form the second largest population centre of Chile. In the Central Valley, south of the Santiago basin, stretches a series of secondary cities, the development of which has been tied to the agricultural success of central Chile. Among them are Rancagua, Curicó, Talca, Chillán, and Los Angeles. All of these cities are connected by rail and the Pan-American Highway.

Most of Chile's cities were founded during the colonial era, and they were arranged around a central square (*plaza de armas*). The original buildings were made of adobe (sun-dried brick) and wood, materials that would deteriorate or burn. Most of the colonial buildings fell prey to earthquakes and fires; much rebuilding took place and the cities of central Chile have become showcases of modern urbanization, high population density, and bustling commercial and industrial activities. On the coast of the southern Central Nucleus lies Concepción and its port city of Talcahuano, both industrial centres.

Norte Chico, the semiarid north-central part of Chile, developed in close association with the Central Nucleus. Agricultural production and mining characterize this region, of which La Serena, near the coast, and the port of Coquimbo are the major centres. The population is primarily concentrated in the irrigated valleys of the Copiapó, Huasco, Elqui, and Limarí rivers or else dispersed in the mountains, where there are mining activities. The main cities, somewhat smaller than those of central Chile, are located in the valleys: they include Copiapó, in the valley of that name, the most important mining centre of the country during the 19th century; Vallenar, Ovalle, and Vicuña. Agriculture, goat raising, and iron and copper mining are the main economic activities. From this region come the famous pisco (a white brandy distilled from sun-dried grapes), fine wines, and high-quality fruits for export.

During colonial times, the fringe of territory at the southern extreme of the Central Nucleus was bitterly contested by Spaniards and Araucanians, the original Indian population, which gave the northern part of south-central Chile its name, La Frontera ("The Border"). After the pacification of the Araucanians in the 1880s, the area was gradually settled by Chileans and by European colonists

La Frontera



Population density of Chile.

who had already begun immigrating there in the 1850s. It developed in modern times as a region of grain growing and commercial pine forestry for cellulose manufacture. The regional capital is Temuco, and in the surrounding countryside still live—in rather precarious conditions—a concentration of Araucanians, locally called Mapuche.

Colonization of the Lake District, located south of La Frontera, began after 1850 with immigrants from Germany, Switzerland, and Belgium. Homesteads, rather than large haciendas as in the Central Nucleus, became the pattern of rural settlement. Although the land has been consolidated in recent times, land fragmentation is still visible. The largest city of this region is Valdivia, founded in early colonial times. This once active industrial centre for footwear, textiles, brewing, and shipbuilding declined after most of its manufacturing installations were destroyed by a 1960 earthquake. Osorno and Puerto Montt are other regional centres, specializing in dairy and flour production. The scenic piedmont lakes and the snow-capped volcanoes attract a steady flow of tourists.

The extreme north and the extreme south could be considered the population and resource frontiers. Both are sparsely populated and rich in natural resources. Settlement of the arid Norte Grande in northernmost Chile began in the middle of the 19th century in response to the exploitation of minerals in the interior. A string of coastal cities emerged as export centres for nitrates, borax, and copper. Iquique, once an exporter of nitrates, has become the capital of Chile's fish meal industry. Antofagasta, the railroad terminus to Oruro, Bolivia, is an active administrative and trading centre and an export facility for the Chuquicamata copper mine. Arica, which acts as a port for Bolivia at the end of the railroad to La Paz, supports fish meal plants and oversees the agricultural production of the Azapa Valley. Once the automobile assembly centre of Chile, Arica has lost its prominence as an industrial city. The only city of significance in the interior of the Norte Grande is Calama, adjacent to the Chuquicamata copper mine, the world's largest open-pit mine. Still, the rest of the area remains picturesque. Old Indian towns, scattered oases, and spectacular desert scenery attract tourists. At the Shrine of La Tirana, on the Tamarugal Plain, Indian and mestizo pilgrims from northern Chile, Bolivia, and southern Peru gather for a colourful festival each July.

Norte Grande

The extreme south encompasses three natural units: the Chiloé island group, the Channels region, and Chilean Patagonia and Tierra del Fuego. Chiloé and its neighbouring islands are among the most undeveloped regions of the country; rudimentary agriculture and algae (used in making confectionary products) and shellfish gathering are the main activities. The small towns of Castro and Ancud are the main population centres of the mostly rural habitat. The Channels region is characterized by islands, separated by glacially carved channels, where colonization has been unsuccessfully attempted since the 1920s. Outlying towns such Puerto Aisén and Coihaique are the only population centres. The region of Magallanes, hinged on the Strait of Magellan, is the most developed area of Chilean Patagonia and Tierra del Fuego. Sheep raising estancias (ranches), which have exported wool since the late 19th century, and oil and natural gas, which have been exploited since 1945, are the pillars of its economy. These activities, combined with meat-packing plants and the trading functions of Punta Arenas, have made this one of the more modernized parts of Chile.

The extreme south

THE PEOPLE

The Chileans are racially a mixture of Europeans and American Indians. The first miscegenation occurred during the 16th and 17th centuries between the indigenous tribes, including the Atacameños, Diaguitas, Picunches, Araucanians (Mapuches), Huilliches, Pehuenches, and Cuncos, and the conquistadores from Spain. Basque families who migrated to Chile in the 18th century vitalized the economy and joined the old Castilian aristocracy to become the political elite that still dominates the country. Few blacks were brought to Chile as slaves during colonial times because a tropical plantation economy, common in much of the New World, did not develop.

After independence and during the republican era, English, Italian, and French merchants established themselves in the growing cities of Chile and incidentally joined the political or economic elites of the country. The official encouragement of German and Swiss colonization in the Lake District during the second half of the 19th century was exceptional. The censuses of the late 19th century showed that foreigners—principally Spaniards, Argentines, French, Germans, and Italians—formed scarcely more than 1 percent of the total population. At the turn of the century, small numbers of displaced eastern European Jews and Christian Syrians and Palestinians fleeing the Ottoman Empire arrived in Chile. Today they spearhead financial and small manufacturing operations.

Racial mixture

The population displays a strong sense of cultural identity, which can be traced to the predominance of the Spanish language, the Roman Catholic religion, and the comparative isolation of Chile from the rest of South America. The Araucanian Indians form the only significant ethnic minority.

The trend of age-group distribution of Chile's more than 12,000,000 people, with increasingly larger numbers in the older brackets, reflects a progressive maturing of the population. Life expectancy rose from 57 years in 1960 to about 70 years by the early 1980s. These demographic changes reflect both improved health-care conditions and modernization of the life-style by the predominantly urban population. Also ascribed to the same factors is the dramatic decline during the late 20th century in infant mortality and in the fertility rate. Chile's crude death rate is lower than that of most of its South American neighbours.

The large cities and the industrial centres of central Chile attract a steady flow of internal migrants. Most of them head for the capital city of Santiago, with the rest going primarily to Valparaíso–Viña del Mar and to Concepción–Talcahuano. These migrants emanate mostly out of the rural regions of the Central Valley and north-central Chile. The northern coastal cities receive some migrants from Santiago and Valparaíso and also from the small villages in the far north. Chiloé has been losing its population to Punta Arenas and the agrarian areas of the Lake District, and even to Argentina, where Chilotes work on estancias or in the mines of Patagonia. After 1973, hundreds of thousands of Chileans left the country for political reasons to live in exile.

Internal migration

THE ECONOMY

The Chilean economy is based on the exploitation of agricultural, fishing, forest, and mining resources. Chile developed historically on the basis of a few agricultural and mineral exports, as was common in Latin America. Many manufactured products had to be imported, and land, wealth, and power were concentrated in the hands of a small aristocracy. Although there have been land reforms and development of manufacturing, many of Chile's economic problems in the 20th century are related to the country's early economic structure.

During the 19th century the Chilean economy grew on the basis of exported agricultural products, copper, and nitrates. After the nitrate market dropped during World War I, Chile's economy took a sharp downturn, intensifying the effect on the country of the Great Depression. These events turned Chile toward more socialistic programs that featured strong government control of the economy. An attempt was made to develop import substitution industries so as to lessen dependence on imported products. Industrial growth was placed in the hands of the Corporación de Fomento de la Producción (Corfo; the Development Corporation). Agrarian reforms were instituted, and the government assumed greater control of industry, especially during the administrations of Pedro Aquirre Cerda (1938–41) and Salvador Allende Gossens (1970–73), when many banks, copper mines, and business firms were nationalized. The economy at first improved under these policies, inflation going down and the gross domestic product increasing. The government, however, was unable to establish a sound tax base to match the expanding economy; by 1973 conditions were deteriorating rapidly and a military coup overthrew the government.

Economic development

The new regime instituted more conservative, free-market programs and reversed many of the previous governments' acts. The country has continued to face severe economic problems, reflected in periodic high inflation, fluctuating trade policies, unemployment, and heavy dependence on a single major export, copper, in an unstable market.

Resources. A geographically varied country, Chile is rich in mineral deposits, natural forests, sea resources, and energy sources.

Mineral resources, noncarboniferous. Mining, historically the mainstay of the Chilean economy, has been a catalyst for both external commerce and domestic industrial development. Copper, molybdenum, iron, nitrates, and other concentrated minerals make up a large part of the total value of national exports.

Metals account for the highest percentage of mining exports, copper being primary. Chile is the world's largest producer and exporter of copper. Copper mines are located in northern Chile (Chuquicamata and El Salvador) and along the Andes of north-central Chile (especially El Teniente and Andina). Small-scale extractions are carried out by individuals, or *pirquineros,* who operate in the uplands of north-central Chile and in the coastal ranges of central Chile. Medium-sized activity is conducted by companies with larger investment capacities and with their own treatment plants. Large-scale mining was developed with U.S. capital at the beginning of the 20th century.

Copper

Copper plays the role in the Chilean economy that was occupied by nitrates prior to World War I. The large U.S. corporations were tranformed into mixed-ownership enterprises during the late 1960s and totally nationalized during the early 1970s, when mining and sales were turned over to the Corporación Nacional del Cobre de Chile (Codelco). A drop in world market prices influences production and sales and creates financial hardship.

Iron-ore mining in El Tofo and El Romeral, both in north-central Chile, is significant, and manganese, silver and gold, and molybdenum (a metal derived from the large copper deposits) are also mined. Among nonmetallic minerals, sulfur, gypsum, lithium, and limestone are moderately exploited. Nitrate deposits occur in the northern interior desert. Their economic value, so important during the 19th century, has decreased, but the production of iodine, a by-product of nitrate, is of major importance.

Energy resources. Hydroelectric potential and installed capabilities, as well as coal and moderate oil and natural gas reserves, furnish Chile with good energy resources. The steady flow of the Andean rivers has been used by the Empresa Nacional de Electricidad (ENDESA; National Electric Company) to produce electricity. Hydroelectric development has been extended to the coastal mountain ranges. Prior to the installation of Chile's huge hydroelectric system, most of the country's energy was obtained from soft coal, mined since the 19th century in the Gulf of Arauco, south of Concepción. Oil and natural gas are extracted on Tierra del Fuego and along the northern shore of the Strait of Magellan and are shipped to refineries in central Chile. Production, however, meets only about half of the country's oil needs.

Hydroelectric potential

Forestry resources. South of the Bío-Bío river, climatic conditions favour the growth of natural forests. The primary species used for lumber and paneling are the coigue, oak, rauli, ulmo, tepa (laurel tree), and monkey puzzle tree. Pine for the manufacture of paper and pulp is taken from forests in central Chile and the Bío-Bío region.

Fishing resources. Since 1974, after the collapse of the Peruvian fishing industry, Chile has become the chief fishery of South America, and it is one of the foremost fishing nations of the world. Sardines, jack mackerel, chub mackerel, hake, and anchovy constitute most of the catch. The principal products are fish meal and fish oil, which are shipped to Europe and the United States for the production of animal feed and industrial oil. The fish-processing plants—all privately owned—are mainly located in the northern cities of Iquique, Arica, and Antofagasta.

Agriculture. While good climatic conditions and abundant water resources favour Chile's agriculture, outdated land-tenure patterns, managerial ineptitude, and inadequate price policies have combined to make agriculture one of the most inefficient sectors of the economy. Employing approximately one-sixth of the labour force, agriculture generates less than one-tenth of the gross domestic product. To meet expenditures and credit payments abroad, the military government that took over in 1973 strongly encouraged exports of agricultural commodities by private national and international companies. Within the framework of this policy, Chile increased remarkably the export of fresh fruit, canned vegetables, and wines.

In temperate central Chile the primary crops are cereals (chiefly wheat), followed by grapes, potatoes, corn (maize), apples, beans, rice, and a variety of vegetables. Industrial crops, such as sugar beets and sunflower seeds for cooking oil, are also common.

Stock raising has been one of the most underdeveloped activities in rural areas, partly because of poor technology and inefficient breeding. Cattle are the major livestock. There has been, however, some expansion in poultry, lamb, and pork production, as well as that of beef.

Industry. An estimated 15 percent of the economically active population is employed in the industrial sector, which accounts for about one-fifth of the gross domestic product. Factories are concentrated in the principal urban centres—Santiago, Valparaíso, and Concepción. Light industries produce appliances, chemical products, food products, textiles and clothing, and construction materials.

Larger industrial complexes are located at the San Vicente harbour of Concepción; they include the Huachipato iron and steel mill, fish-processing factories, and a petroleum refinery associated with a petrochemical complex. Another such refinery is situated in Concón, at the mouth of the Aconcagua River. Pulp and paper mills thrive in the vicinities of the Bío-Bío and Laja rivers. (C.N.Ca.)

Trade and finance. Chile's principal markets for mining and agricultural commodities are Europe, the United States, and East Asia. Most imports are from the United States, Brazil, Japan, Argentina, Germany, and France. The balance of payments, generally unfavourable since the 1950s because of increased foreign expenditures and payment of external loans, showed occasional improvement after 1976 but with considerable fluctuation.

Balance of payments

The Banco Central de Chile, established in 1925, is the official bank of the nation; it implements the internal banking policies of the government and also conducts foreign trade. In 1989 the bank became an autonomous institution entirely responsible for the country's financial and exchange-rate policies. The Banco del Estado de Chile is also a state entity, but it functions as a private commercial bank. National private banks as well as international banks from Europe, the United States, and Asia operate freely in the country.

Within the Chilean economic system there is collaboration between the private and public sectors, with the private sector contributing an increasing percentage of the total annual investment. Private businesses are generally organized as joint-stock companies (similar to U.S. corporations) that participate in all areas of economic activity.

Transportation. The country's length and physical barriers constrain communication and traffic flow. Only the sea offers an expeditious means of transportation, which was taken advantage of during the 19th century when Chile owned one of the largest merchant fleets in Latin America. Chile's overall economic decline during the early 20th century and the supplanting of maritime transport with overland means resulted in the reduction of the fleet. Eventually only international transport was conducted by ship. The main port of entry is Valparaíso. San Antonio, the port for Santiago, exports copper and agricultural commodities. Other ports, such as Antofagasta and Arica, serve the trade with Bolivia. Chañaral, Huasco, Guayacán, and Tocopilla export minerals. The port of Talcahuano serves the industrial complex of Concepción.

The development of an overland transportation system began with two railway systems initiated about the turn of the century: the northern network, between La Calera (near Valparaíso) and Iquique, now in disuse, and the southern network, between La Calera and Puerto Montt. The most traveled sections connect Santiago with Valparaíso and Santiago with Puerto Montt; both sections

are electrified, making them more competitive with road transportation. The railway system is controlled by the Empresa de los Ferrocarriles del Estado (State Railway Enterprise). International railroads connect Arica and La Paz (Bolivia), Antofagasta and Oruro (Bolivia), and Los Andes and Mendoza (Argentina). A railbus transports passengers over the short route between Arica and Tacna (Peru).

Highways

Chile's rapid motorization has brought enhanced highway transportation for passengers and goods. The backbone of the Chilean road system is the paved Pan-American Highway, which connects Arica with Puerto Montt, near Chiloé Island, a distance of more than 2,100 miles. From this main artery secondary routes connect numerous cities, including Santiago, with the ports of San Antonio and Valparaíso, Bulnes with Concepción, and Los Lagos with Valdivia. The most important international paved road connects Santiago with Mendoza (Argentina). All-weather roads connect Iquique with Oruro (Bolivia), Antofagasta with Salta (Argentina), La Serena with San Juan (Argentina), Osorno with San Carlos de Bariloche (Argentina), and Punta Arenas with Río Gallegos (Argentina).

Air transport serves mostly the cities at both extremes of the country and some towns of difficult access, such as El Salvador and Coihayque. The main airline is Línea Aérea Nacional de Chile (LAN; National Airline of Chile). A tourist service is maintained by LAN between Santiago and Easter Island, in the Pacific, with the flight continuing to Papeete, Tahiti. All major South American lines, plus others from the United States and Europe, handle the flow of international passengers to the Arturo Merino Benítez airport near Santiago.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The Republic of Chile, inaugurated in 1821, has had a long history of representative democracy, with only a few short-lived exceptions. Historically, Chile has been renowned for its political freedom. From September 1973 to March 1990, however, a military junta headed by Gen. Augusto Pinochet Ugarte presided over the longest period of authoritarian dictatorship in Chilean history. The country is governed in accordance with the constitution of 1981, approved by a plebiscite called by General Pinochet to change the constitution of 1925. The 1981 document placed the administration of the state into the hands of the president and permitted Pinochet to hold office until 1990. The president appoints the state ministers.

Under the 1981 constitution a presidential candidate chosen by the junta was to be put up for approval in a national plebiscite and, if approved, to serve as president until 1997. The junta nominated Pinochet, who was rejected in the 1988 plebiscite, and the first presidential elections since the 1973 coup were held in December 1989.

The bicameral National Congress was dissolved at the time of the 1973 coup, after which legislative functions were carried on by the junta, assisted by legislative commissions. The 1981 constitution allows for a bicameral legislature consisting of an upper chamber, or Senado, and a lower chamber of representatives, or Cámara de Diputados, to be elected by direct popular vote. These two bodies remained in recess until the elections of December 1989.

The constitution of 1981

The justices and prosecutors of the Supreme Court and the Courts of Appeals are appointed by the president from a list of nominees proposed by the Supreme Court. Judges are career functionaries of the Ministry of Justice. The composition of the lower courts is similarly determined.

Local government is carried on through 12 administrative regions and the capital, Santiago. The regions are divided into provinces, which in turn are divided into communes. The president appoints the intendents (*intendentes*) who head the administrations of the regions and Santiago. The intendents govern with the aid of a regional council, which may include the governors of the constituent provinces and representatives of various other private and public institutions within the region. The provincial governors, like the intendents, serve at the sole pleasure of the president. The communes are administered by a municipal corporation (*municipalidad*) composed of a mayor (*alcalde*) and a communal council. The mayor is appointed by the regional council from a list of three candidates submitted by the communal council; in the case of some larger urban centres, the mayor is appointed directly by the president. The councilmen (*regidores*) are elected by popular vote for four-year terms.

In September 1973, when the junta suspended all activity by political parties and outlawed Marxist parties, the political spectrum extended from right through centre to left. At the extreme right stood the National Party (Partido Nacional)—an alliance formed in 1965 that included the former Liberal Party (Partido Liberal) and United Conservative Party (Partido Conservador Unido)—and the Radical Democrats (Democracia Radical)—the right wing of the once-populist Radical Party (Partido Radical; see below), from which it split in 1969. The centre was occupied by the Christian Democratic Party (Partido Demócrata Cristiano), which, since the congressional elections of 1965, had attracted the most voters. With many of its partisans coming from the extensive Chilean bureaucracy, the social democratic Radical Party had been another important centrist party, but after 1965 it drifted to the left, where in 1973 it was reduced to a minority partner. The core of the left consisted of the Socialist Party (Partido Socialista) and the Soviet-oriented Communist Party of Chile (Partido Comunista Chileno). Several Marxist groups affiliated with the two major powers of the left included the Unified Movement of Popular Action (Movimiento de Acción Popular Unitaria), the Christian Left (Izquierda Cristiana), and the extremely militant Movement of the Revolutionary Left (Movimiento de Izquierda Revolucionaria).

After 1980 General Pinochet eased his severe repression of political activism, and in 1981 a few political exiles were allowed to return to Chile, but political activity was still heavily restricted. The rightist groups rallied in a short-lived movement called the National Democratic Accord (Acuerdo Democrático Nacional). The parties of the centre, led by the Christian Democrats, formed the Democratic Alliance (Alianza Democrática). The exiled leaders of the left split into the Socialist Convergence (Convergencia Socialista), which in 1983 merged into the Chilean Socialist Bloc (Bloque Socialista Chileno), and an ephemeral movement that was dominated by the Communist Party of Chile. Reluctant to join forces with the Socialist Convergence in opposing the Pinochet government, the Christian Democratic Party isolated itself from both the right and the left, and this climate of dissension weakened the opposition.

Political parties

To organize opposition to Pinochet in the 1988 plebiscite, 16 centrist and leftist parties formed the Command for No (Comando por el No), which after Pinochet's defeat became the strongest opposition group and was renamed the Coalition of Parties for Democracy (Concertación de los Partidos por la Democracia). In July 1989, constitutional amendments worked out between the government and the opposition were approved in a national referendum; included was the revocation of Article Eight, which banned Marxist parties. Two months later the government declared, with some restrictions, that all political exiles were permitted to return to Chile. In December 1989 the Christian Democrat Patricio Aylwin Azócar won Chile's first free presidential elections since the 1973 coup, and moderate and leftist parties won numerous seats in legislative elections. Democratic systems continued to strengthen, and by 2000 Ricardo Lagos was elected as the nation's first socialist president since Allende. (C.N.Ca./Ed.)

Education. Chile's educational system, structured along the lines of 19th-century French and German models and highly regarded among Latin-American countries, is divided into eight years of free and compulsory basic (primary) education, four years of optional secondary or vocational education, and additional (varying) years of higher education. Education is received by most primary-school-age children, accounting for the low illiteracy rate of 4 percent for persons 12 years of age and over. Private schools, which are run by religious congregations, ethnic groups (such as German, French, Italian, and Israeli), and private educators have relatively high enrollments and cater to affluent families.

University education in Chile is of considerable renown throughout Latin America. The major institution is the

Chilean universities

University of Chile (originally founded in 1738), with campuses in Santiago, Arica, Talca, and Temuco. The University of Santiago of Chile and the Federico Santa Marta Technical University, in Valparaíso, are technical universities patterned after the German model. Private universities are the Catholic University of Chile in Santiago, the Catholic University of Valparaíso, the University of the North in Antofagasta, the University of Concepción, and the Southern University of Chile in Valdivia.

Health and welfare. Social welfare and labour legislation evolved earlier in Chile than it did in other Latin-American countries, and they have reached a high level of development. Legislation was passed in the early part of the 20th century that regulated labour contracts, workers' health, and accident insurance. In successive years the social security system expanded in an attempt to cover all labour sectors. All workers were eventually covered by the Social Insurance System, maintained through contributions of employers, employees, and the state. Since 1973 the military government has changed social security into an individual savings scheme in which workers invest with private companies.

Health care also developed remarkably during the first half of the 20th century by means of state health plans managed by the National Health Service, a subsidiary of the Ministry of Public Health. An increasing number of facilities, equipment, and qualified personnel have reduced morbidity and infant mortality, eradicated tuberculosis, and brought infectious diseases under control. A movement by the Pinochet government to modify the state-administered public health system by introducing a profit-oriented private health system began in 1980. It offered the option of private health care to those who could afford it.

Public health

CULTURAL LIFE

Language and a common history have promoted cultural homogeneity in the country. Even the Araucanians and certain Aymara minorities in the north share the values of the Chilean identity, while continuing to cherish their own cultural heritage. Chileans have always displayed a high degree of tolerance toward the customs and traditions of minority groups, as well as toward Christian and non-Christian religious practices.

The flavour of local custom and tradition in Chile is readily observable in the numerous colourful religious festivals that take place at various localities throughout the country. Hundreds of thousands of spectators are drawn to these processions.

The arts. Literature, poetry in particular, is the most significant of the creative arts in Chile. Two Chilean poets, Gabriela Mistral and Pablo Neruda, won the Nobel Prize for Literature (1945 and 1971, respectively), and the poetry of Vicente Huidobro and Nicanor Parra, also of the 20th century, is recognized in the world of Hispanic literature. Fiction, on the other hand, has not been a successful genre, perhaps because of its marked parochialism. Manuel Rojas enjoyed, during the 1950s and 1960s, a degree of international popularity, and more recently the novels of Isabel Allende have become highly acclaimed not only in Latin America but also, in translation, in Europe and North America.

Performing arts

Much of the fine and performing arts of Chile is centred in Santiago, and the main season for cultural events is between March and November. The most famed Chilean musician has long been the pianist Claudio Arrau. Composers such as Enrique Soro and Juan Orrego are noted in the Latin-American world of music, but they never achieved world recognition. The Chilean National Symphony Orchestra and several chamber music ensembles keep European musical culture alive in Chile. Dance and opera are highlighted by the Municipal Ballet and Opera and the National Ballet of the University of Chile. Contemporary folk music, particularly *tonadas* (poetic tunes accompanied by guitar), had its halcyon days in the 1960s and early 1970s, when protest and social-content songs were fashionable. Violeta Parra, who died in 1969, excelled in this style.

Santiago in particular is a hub of art galleries where the works of Chile's artists are displayed and sold. The country, however, has produced few artists of high acclaim. The painter Roberto Matta Echaurren and the sculptor Marta Colvin are among those of significance.

Cultural institutions. The country, and Santiago in particular, is rich in museums of fine arts; modern, folk, colonial, and pre-Columbian art; natural history; and Chilean national history. The Museum of National History is of particular note, and others include the Museum of Fine Arts, the Museum of Contemporary Art, and the Museum of Natural Science, all in Santiago. The main library, the National Library of Chile, ranks among the largest in Latin America.

Museums

Recreation. There is ample recreational and sports opportunity in Chile; the people can engage in most such activities common to Western cultures. The Pacific beaches are notably beautiful, but the cold water encourages more sunbathing than swimming. Viña del Mar is a particularly well-known summer resort, and the scenery of the Lake District to the south attracts many tourists. As in many Latin-American countries, football (soccer) arouses a particular devotion among the populace, and crowds of up to 80,000 attend matches in Santiago. In this mountainous country skiing is enjoyed by devotees who flock to ski resorts, such as those at Portillo and Farellones (near Santiago) and those near Chillán to the south.

Press and broadcasting. The degree of literacy and the demand for national and international information keeps a large number of journals and magazines in publication. Prior to the 1973 military coup, practically all political groups published their own daily or weekly journals. After the coup only journals that refrained from criticizing the government were allowed and censorship was strict and implacable. After 1981, books of political content or dissent were allowed to be published, provided the author was not suspected of being a Marxist. Radio and television stations followed policies of focusing attention away from poignant socioeconomic and political problems of the country. By tradition the stations have been operated by the universities but as commercial, profit-oriented enterprises. In 1967 a government channel was founded, which was used by subsequent administrations to disseminate propaganda.

State control of media

For statistical data on the land and people of Chile, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR. (C.N.Ca.)

History

PRECOLONIAL PERIOD

At the time of the Spanish conquest of Chile in the mid-16th century, at least 500,000 Indians inhabited the region. Nearly all of the scattered tribes were related in race and language, but they lacked any central governmental organization. The groups in northern Chile lived by fishing and by farming in the oases. In the 15th century they fell under the influence of expanding civilizations from Peru, first the Chincha and then the Quechua, who formed part of the extensive Inca Empire. Those invaders also tried unsuccessfully to conquer central and southern Chile.

Original inhabitants

The Araucanian Indian groups were dispersed throughout southern Chile. These mobile peoples lived in family clusters and small villages. A few engaged in subsistence agriculture, but most thrived from hunting, gathering, fishing, trading, and warring. The Araucanians resisted the Spanish as they had the Incas, but fighting and disease reduced their numbers by two-thirds during the first century after the Europeans arrived.

The Spanish conquest of Chile began in 1536–37, when forces under Diego de Almagro, associate and subsequent rival of Francisco Pizarro, invaded the region as far south as the Maule River in search of an "Otro Peru" ("Another Peru"). Finding neither a high civilization nor gold, the Spaniards decided to return immediately to Peru. The discouraging reports brought back by Almagro's men forestalled further attempts at conquest until 1540–41, when Pizarro, after the death of Almagro, granted Pedro de Valdivia license to conquer and colonize the area. Valdivia, with about 150 companions, including his mistress, Inés Suárez, the only Spanish woman in the company, entered

Chile in late 1540 and founded Santiago (Feb. 12, 1541). For the next two decades the settlers lived a precarious existence and were constantly threatened by the Indians, who resisted enslavement. Before the safety of the colony was guaranteed, land was apportioned to the conquerors, and thus began the system of large estates. The estates were later institutionalized through the *mayorazgo,* a practice of transmitting estates by entail.

The establishment of estates

Valdivia did not undertake the conquest of the region south of the Bío-Bío River until 1550. In that year Concepción was founded, and preparations were made to move southward. During the next two years settlements and forts were established in La Frontera, but in 1553 the Araucanian Indians, under a skilled military chieftain named Lautaro, rose in a revolt that led to the capture and death of Valdivia and to the beginning of a costly struggle. The Araucanians, often referred to as the Apache of South America, kept the struggle alive until the 1880s by successfully adapting their way of life and military tactics to changing conditions.

Although Concepción was destroyed on several occasions, it remained as the Spanish outpost in the south as did La Serena, founded in 1544, in the north. The province of Cuyo held the same position east of the Andes until 1776, when it was made a part of the newly created Viceroyalty of the Río de la Plata. The conquest of Chile was finally consolidated during the late 1550s under Gov. Don García Hurtado de Mendoza. Before the end of the 16th century English pirates and freebooters, including Sir Francis Drake and Thomas Cavendish, and later Dutch adventurers harassed the coast in search of sudden wealth and as part of a prolonged effort to force Spain to permit neutral nations to trade with its New World colonies.

COLONIAL PERIOD

Because only quite limited amounts of precious metal were found in Chile, the settlers early turned their attention to agriculture. They grew a wide variety of cereals, vegetables, and fruits; raised livestock; and consumed nearly all of their production locally. Largely because of the poverty of the colony, there were never more than a few thousand black slaves; and, because the Indians proved to be an unreliable source of labour, the settlers often had to work the fields themselves. The lack of mineral wealth also made the area unattractive to Spaniards, and at the end of the 16th century there were no more than 5,000 Spanish settlers in the entire colony. In this regard it should be pointed out that, beginning in 1600 and continuing until trade restrictions were relaxed in the late colonial period, Chile was a "deficit area" in the empire, and the Spanish crown had to provide an annual subsidy to meet the expense of maintaining officials in Santiago and an army on the Araucanian frontier.

Chile lived under the same administrative and religious systems as its neighbours, but because the colony was poor, there was until the 18th century a tendency to send mediocre officials to preside over its destinies. The Spanish crown and the Roman Catholic Church combined to limit the colonists' administrative experience and economic development. The power of the captain-general, the highest royal official in the colony, was absolute. Appeals to the viceroy in Peru or the king in Spain were always possible, at least in theory. Chilean trade was tightly controlled from Peru. The influence of the Catholic Church in secular affairs was always significant and frequently decisive.

Growth of the mestizo group

The most apparent social development after 1600 was the rapid growth of a mestizo (mixed Indian and European) group, which gives present-day Chile its homogeneous ethnic character. By the end of the colonial period, when the population reached an estimated 500,000 (not including unsubjugated Indians), approximately 300,000 were mestizos and about 150,000 were Creoles (native-born persons of European descent). About 20,000 were *peninsulares* (recently arrived Spaniards), perhaps 15,000 were blacks, and a handful were recently emancipated Indians. Society was highly structured, with *peninsulares* at the top, followed by Creoles, mestizos, Indians, and African slaves. At the end of the colonial period, the vast majority of the population was concentrated in the Aconcagua Valley and the Central Valley (extending from Santiago to Concepción), which together form "the cradle of Chilean nationality."

Education in colonial Chile was almost a complete monopoly of the Catholic clergy and reinforced the society's strong class differences. In 1758, however, courses were opened in the Royal and Pontifical University of San Felipe at Santiago and attracted students from the Spanish colonies across the Andes. Nonetheless, intellectual life in Chile developed slowly. The colony did not have a printing press until shortly before it won independence from Spain in 1818, and the paucity of contacts with the outside world reinforced its insularity.

STRUGGLE FOR INDEPENDENCE

Despite the colony's isolation, its inhabitants at the start of the 19th century were affected by developments elsewhere. The most significant of those developments were the winning of independence by the 13 Anglo-American colonies and by Haiti, the French Revolution, and the inability of Spain to defend its system in America, as indicated by the British invasion of the La Plata region and increased contraband trade on the part of British and U.S. citizens. Finally and decisively came the intervention of Napoleon in Spain, an act that in 1808 threw Chile and the other colonies on their own resources and led them to take the first steps toward greater autonomy and self-government. In Chile the initial move toward independence was made on Sept. 18, 1810, when a *cabildo abierto* (open town meeting) in Santiago, attended by representatives of privileged groups whose vaguely defined objectives included a change in administration, accepted the resignation of the President-Governor and in his place elected a junta composed of local leaders.

From 1810 to 1813 the course of the patriots was relatively peaceful because they were able to maintain themselves without formal ties to the Viceroyalty of Lima. Trade restrictions were relaxed; steps were taken toward the eventual abolition of slavery; a newspaper was established to publicize the beliefs of the patriots; and education was promoted, including the founding of the National Institute. However, the embers of civil strife were also fanned. The Creoles were divided over how far the colony should go toward self-government. José Miguel Carrera and his brothers, whose desire for complete independence was equaled if not surpassed by their personal ambition, inflamed the issues. Meanwhile, Spain had taken steps to reassert its control over the colony. At the Battle of Rancagua, on Oct. 1 and 2, 1814, it reestablished its military supremacy and ended what has been called *la patria vieja* ("The old fatherland").

The Carrera brothers

Following the defeat at Rancagua, patriot leaders, among them the Carrera brothers and Bernardo O'Higgins, future director-dictator of Chile, migrated to Argentina. There O'Higgins won the support of José de San Martín, who, with the support of the revolutionary government in Buenos Aires, was raising an army to free the southern portion of the continent by first liberating Chile and then attacking Peru from the sea. The Carreras continued their spirited agitation for independence in Buenos Aires and the United States.

Meanwhile, many of those who remained in Chile suffered from the harsh rule of Spain's inept representatives and became convinced that absolute independence was necessary. In January 1817 San Martín's well-drilled army, with O'Higgins as one of its commanders, began its march across the Andes; and on Feb. 12, 1817, the patriot forces defeated the royalists on the hill of Chacabuco, which opened the way to Santiago. O'Higgins was proclaimed supreme director of Chile, although the act of declaring Chile's independence was not taken until a year later (Feb. 12, 1818), on the first anniversary of Chacabuco; and the decisive defeat of Spain on the Chilean mainland (Spain held the island of Chiloé until 1826) did not come until the Battle of Maipú, on April 5, 1818. Before emancipation was assured, O'Higgins began the creation of the Chilean navy, which by late 1818 was in the process of clearing the Chilean coast of Spanish vessels.

The liberation of Chile

Chile was free, but its inherent weaknesses were every-

where manifest. The Creoles remained bitterly divided between O'Higgins and the Carreras. Two of the Carrera brothers had been executed in Mendoza, Arg., in 1818; and José Miguel Carrera suffered the same fate in the same city in 1821. The elite groups were dedicated to the retention of those institutions on which such things as law, property, family, and religion were founded. The masses, who had been little more than spectators in the conflicts between 1810 and 1818, were excluded from government.

(J.J.Jo./P.W.D.)

CHILE FROM 1818 TO 1920

The Chilean oligarchy had little sympathy with O'Higgins, who favoured reducing their privileges. They accepted him, however, because he was supported by the army and because of dangers posed by Spaniards still in Peru and in parts of Chile (Valdivia and the island of Chiloé) and by internal guerrillas loyal to the Spanish monarchy. Opposition to O'Higgins began to make itself heard once the Chilean-Argentine army expelled the Spaniards from Peru; it increased after 1822, when the Chileans succeeded in driving the remaining Spaniards from Chile. O'Higgins' attempt, by means of a new constitution, to concede a larger political role to the oligarchy did not increase his support, and general unrest and poor harvests forced him to abdicate in 1823.

O'Higgins' abdication

The years 1823–30 were troubled by an internal political split between the oligarchy and the army; 30 successive governments held office, and a variety of political experiments were tried. Rivalries developed between federalists and centralizers and between authoritarians and liberals. To the political chaos were added financial and economic disorder and an increase in lawlessness that tended to strengthen the authoritarian members of the oligarchy. Rival political factions were eliminated in 1829 when authoritarians, with the help of a part of the army, were able to install a junta (collegial government) that nominated José Tomás de Ovalle as provisory president. Actual power, however, was held by Diego Portales, who, as either a cabinet member or a private citizen, in fact ruled as a virtual dictator.

The conservative hegemony, 1830–61. During the next 30 years, Chile established its own definitive organization, made possible by a compromise among the members of the oligarchy. Portales played an important role in the compromise, and a new constitution achieved as a result (1833) remained the basis of Chilean political life until 1925. It created a strong central government, responsive to the influence of the landowning class, which controlled the parliament.

The establishment of this new political structure united the different factions that brought Ovalle and later Joaquín Prieto to power. The new government was strengthened by a successful war against the Peruvian-Bolivian Confederation (1836–39), during which it broadened its support by reinstating army officers ousted when the conservatives had seized power in 1829–30.

Economic prosperity. The government of Prieto and the succeeding governments of Manuel Bulnes and of Manuel Montt dedicated themselves to developing the economy. Their first and most pressing need was to reestablish the state finances, exhausted by the war. To this end, measures were taken to expand the principal source of state income—foreign trade. A free port was created at Valparaíso to encourage trade by foreign, especially British, merchants. These measures, however, would not have worked if Chilean products had not found new markets abroad. The discovery of gold in California (1848) and in Australia (1853) assured Chilean grain a vast market as the populations of those two areas expanded. The production of silver and copper increased in response to European demand, thereby increasing the wealth of the state and the dominant class. The economic development helped overcome political disagreements and aided the consolidation of internal peace.

Modernization

Political stability and economic prosperity opened the way to modernization: the construction of the first railroads began, new roads were opened, and the harbours were improved. The government tried also to develop education, though largely for upper-class children. The University of Chile was founded, and foreign scholars were recruited to foster geologic, botanical, and economic studies. The development of commerce attracted numerous foreign entrepreneurs (British, French, and North American), who came to dominate the import-export trade.

Political diversification. The increase of wealth that especially favoured the oligarchy and foreign merchants also contributed to a diversification of the ruling class; the development of mining production in the north and of agriculture in the south created new fortunes, whose owners soon made their entry into the political world. An attempted coup d'état, the "revolution of 1851," failed but was an indication of the political awakening of these new elements. A new development among younger members of the traditional oligarchy was the growth of liberalism and the appearance of political clubs around the middle of the century.

The impact of these forces was felt inside the political establishment, so much so that a minor conflict between the state and the church over the right to make ecclesiastical appointments was sufficient to break the unity of the dominant political class. The oligarchy was divided into two groups: conservatives, who defended the traditional privileges of the church; and nationalists, who maintained the supremacy of the state. A part of each group, dissatisfied by the authoritarian government of President Montt, united and created a separate faction, the liberals.

The widening of liberal influence, 1861–91. The period after 1860, known as the "Liberal Republic," saw the emergence of many rival political groups whose common characteristic—following an unsuccessful armed insurrection by radicals in 1859—was an attempt to gain power by peaceful means.

Political factions. After 1855 the conservative element, supporting the hegemony of the church, had allied with the liberals in opposing President Montt. The radicals joined the alliance against Montt. José Joaquín Pérez (1861–71), though elected with the support of the "nationalists," governed with the help of the liberal-conservative alliance. A division in the dominating political classes occurred about 1872, when the liberals started to draw away from the conservatives; the liberals succeeded in ending the Roman Catholic Church's monopoly in religious matters.

European influences. The fight to secularize the state opened the country to European influences in cultural activities and civil reforms. Young members of the economic and political oligarchy began to travel and study in Europe. They brought back many political, literary, and scientific ideas.

This new political and cultural opening toward Europe was linked to closer economic relations, especially with Great Britain, Chile's main trading partner. The British began to invest directly in Chile, supplying the capital needed to bring about the construction of railroads and the modernization of ports and public services. The increase of imports and the payment of interest from loans aggravated an already weak balance of payments and resulted in a continuing devaluation of the Chilean peso in relation to the British pound sterling.

Balance-of-payments crisis

The War of the Pacific (1879–83). The need to improve its balance of payments attracted Chile to saltpetre mines situated along the Chilean border in the Bolivian province of Antofagasta and in the Peruvian provinces of Tarapacá and Arica. Ill-defined borders and oppressive measures allegedly taken against the Chilean migrant population in these territories furnished Chile with a pretext for invasion. Chile defeated the Peruvian-Bolivian army and annexed these provinces.

The War of the Pacific had broad repercussions. France, Germany, and especially Britain had strong interests in the saltpetre mines, and they threatened to intervene. The United States, hoping to restrict European influence, offered to resolve the conflict by mediation; Chile refused the U.S. offer, fearing that it would have to give up its territorial gains. German support of the Chilean position further impeded European intervention.

The war weakened Chilean finances, and the economic situation continued to worsen. During the presidency of

José Manuel Balmaceda (1886–91) the government tried to claim the revenues from the saltpetre mines and thus to assert major responsibility in economic matters. Nearly all of the oligarchy, however, was looking for a weaker, rather than a stronger, central power and objected to this attempt to strengthen the executive. The clash was resolved in a brief civil war, which ended with Balmaceda's abdication of the presidency.

Political development, 1891–1920. The coalition that overthrew Balmaceda resulted from a large political regrouping of all those who wanted to strengthen the parliament; thus, after the civil war Chile's presidential republic was converted into a parliamentary republic. This meant that the oligarchy, which had extended itself into commerce and banking, needed only to assure itself of control of parliament—and thus of the various ministries—to dominate the political life of the country. In order to remain in office, governments now had to have the confidence of the parliament. What emerged was a continual struggle for power among the factions, which began to organize themselves as real political parties.

Organization of political parties

Growth of the middle and lower classes. The period between 1891 and 1920 was one of intense political activity that saw the formation of new political parties and tendencies that tried to express the political desires of the middle and lower classes. The development of a state bureaucracy and the growth of the railroads and of commerce favoured the formation of social groups with urban concerns, rarely linked to the landed oligarchy, and increasingly aware of their possible political roles.

An active working class developed in the saltpetre mines, in the large public utility enterprises (railways, gas, electricity), and in the many factories that began to appear in the urban centres, especially in Santiago. The first strikes to obtain better salaries and working conditions occurred during this period.

Formation of new political parties. The radical political faction—born as a dissenting wing of the liberals and striving toward the secularization of the country—became the Radical Party in 1888 and tended progressively to voice the concerns of the growing middle class.

The Democratic Party (Partido Democrático; formed 1887) was led by Malaquías Concha, who spoke for the needs of the artisans and a part of the urban workers. Founded by former radicals, this party differed from the Radical Party only in the particular emphasis it gave to the labour movement.

Marxist ideology had begun to spread among Chilean workers. The first socialist group, founded in 1897, advocated anarchism and a worker-controlled economy. It became the Socialist Party in 1901 but had a fleeting life. The increase of strikes and dissatisfaction of the miners, however, led to the formation (1912) in the mining region of a new Worker's Socialist Party (Partido Obrero Socialista), which influenced workers and university students and advocated an international class struggle; it became the Communist Party in 1922.

Decline of the ruling class. The radicalization of the parties of the left was caused largely by the ruling class's neglect of Chile's complex economic and social problems. The ruling class, concerned with protecting its own interests, failed to introduce needed reforms, and as a result the political instability already evident in the late 19th century grew worse. The traditional Liberal and Conservative parties were unable to adapt to the country's changing situation.

Along with the growing political and social problems, the economic situation also worsened. Loans obtained from Britain and, after 1916, from the United States served more to pay the interest on previous debts and to cover state expenses than to allow productive investments. The country consumed more than it produced, and this was translated into an annual inflation rate of more than 10 percent and to the constant devaluation of the currency in relation to the pound sterling and the dollar. Agrarian production barely kept pace with home consumption, but the large landowners were unable to introduce techniques to increase it. Industrial development lagged because of insufficient capital.

Deteriorating economy

CHILE AFTER 1920

Political uncertainty, 1920–38. In the decade following World War I, falling saltpetre sales and rising inflation fueled dissatisfaction among the middle and working classes. They supported the election of the reformist president Arturo Alessandri Palma in 1920. When the legislature blocked his initiatives, discontent spread to middle-class army officers. They intervened in 1924 to force parliamentary passage of his social reforms. Alessandri resigned but the military returned him to power in 1925. In that year the army backed Alessandri's installation of a new constitution, which lasted until 1973. It established a presidential republic, separated church and state, and codified the new labour and welfare legislation.

New presidential republic

In the period between 1924 and 1932, 21 cabinets were formed and dissolved. These were years of profound crises, marked by attempts to create a new political structure by replacing the oligarchy with a new political elite. Under the military dictatorship of Carlos Ibáñez del Campo (1927–31), new economic reforms were tried: new industrial products were developed, the saltpetre mines were partially nationalized, public works were begun, and public education was improved. But these reforms did not touch the economic power of the oligarchy, which remained the principal political force.

Effects of the world depression. The world depression of the 1930s was difficult for Chile's economy because the international demand and the prices for saltpetre and copper plummeted. Chile was forced to reduce imports, which in turn reduced national production. Incomes diminished, while public expenditures grew.

The economic crisis, accompanied by the fall of Ibáñez, permitted the traditional political forces to regain power. They remained in office only briefly, from July 1931 to June 1932, under the presidency of Juan Esteban Montero Rodríguez, because the crisis was so strong that every attempted improvement failed. Power was then gained by a civilian-military coalition that formed the Socialist Republic (from June to September 1932), which spawned the modern Socialist Party. By the end of 1932, however, new elections returned Arturo Alessandri Palma to the presidency.

Return of Alessandri

Return to constitutional normality. Alessandri's second term (1932–38) was characterized by a return to constitutional normality and by the return to power of the old ruling class. Alessandri tried to restore state finances, badly weakened by the crisis. His economic measures attempted to increase mining and industrial production. Public works eased part of the existing unemployment. Social discomfort diminished, but it did not disappear.

The Radical presidencies, 1938–52. The return to constitutional government did not resolve Chile's serious problems. The discontent of the workers and especially of the middle class was manifested in the 1938 presidential election. The Radical candidate, Pedro Aguirre Cerda, won with the support of a coalition of the left.

The presidencies of Aguirre Cerda and Ríos. The period of Radical presidencies can be divided into two parts, separated by 1946. The first part included the presidencies of Aguirre Cerda (1938–41) and Juan Antonio Ríos (1942–46). Aguirre Cerda represented the middle class; his triumph came through the support of a popular front, which included the Radical, Socialist, and Communist parties and also the left-inspired Confederation of Chilean Workers.

Aguirre Cerda's program included measures for increasing industrial output. The Development Corporation (Corporación de Fomento de la Producción; Corfo) was created in 1939 to reduce imports and thus diminish the trade deficit by developing industry, mainly to produce consumer and intermediate goods.

During World War II Chile remained neutral until, in 1942, in a common action with other Latin-American countries, it declared war on Germany, Italy, and Japan. World War II and the Korean War of the early 1950s benefited Chile's economy; an increased demand for copper permitted a rise in incomes, which facilitated the expansion of public education and aided industrial development, thus helping to increase production.

Effects of World War II

The presidency of Gabriel González Videla. During the period from 1946 to 1952, the president was Gabriel González Videla, also of the Radical Party, who gained a plurality with the support of the Communists. The Socialist Party denounced an offer of alliance, however, and the popular front could not be reconstituted. González Videla's first cabinets, between 1946 and 1948, included Communist ministers; but the international Cold War and Chile's internal troubles soon pushed González Videla toward the right. After 1948 he outlawed the Communists and ruled with the support of the Liberal Party.

Economic links with the United States, which had grown after the economic crisis of the 1930s, were strengthened after World War II; U.S. investments in Chile increased from $414,000,000 in 1945 to $540,000,000 in 1950, largely in copper production. By 1952 the United States had loaned $342,000,000 to the Chilean government. The exchange of technicians and professors helped tighten technical and cultural links between the two countries.

Recovery of the political right

The presidency of González Videla saw the strong political recovery of the right. The Radical presidents had failed to transform Chile's economic and social situations. Between 1940 and 1952 Chile's population rose from 5,000,000 to 6,350,000, with the strongest increase in urban areas, which accounted for 52 percent of the total population in 1940 and 60 percent in 1952. Production rose during this period by a rate very close to the rise in population. But social inequities were not reduced.

Political stagnation, 1952–64. Various conditions explain the victory in 1952 of the former dictator Gen. Carlos Ibáñez del Campo. Under Radical rule the middle class had affirmed its political importance without injuring the economic power of the landed oligarchy, but the lower classes fell farther behind the middle and upper strata. In 1949 the vote was granted to women, and the electorate thus expanded from 631,257 in 1946 to about 1,000,000 in 1952. President Ibáñez was the candidate of a heterogeneous front based on his personal charisma, but he was not the choice of particular political parties.

Ibáñez had promised to rule with a strong hand and if necessary eliminate the parliament; but during his six years as president, he ruled with the support of the traditional right, which prevented any attempt at reform. Ibáñez retained the policy of state intervention in the economy and industrial matters inaugurated by the Radical cabinets.

The presidency of Jorge Alessandri Rodríguez. Ibáñez was succeeded (1958–64) by the son of Arturo Alessandri Palma, Jorge Alessandri Rodríguez, who won the support of the Conservative and Liberal parties. To satisfy popular demands without altering profoundly the structures of the country, he launched a public works program that helped absorb the masses of unemployed. At the same time, he tried to reduce the high inflation rate (about 60–70 percent yearly), to augment productivity by reducing taxes on business enterprises, and to stimulate industrial growth by expanding the home market through public expenditure.

The government placed restrictions on salary increases; salaries thus rose more slowly than prices, which continued to increase by about 30 percent yearly. This alienated the voters, and the government had to call for the support of the Radical Party.

New political groupings. Popular discontent helped revive the Marxist-inspired Socialist and Communist parties and produced an electoral loss of the parties of the right that corresponded with the rise of those of the left. The Christian Democratic Party, a centrist reform party founded in 1957, enjoyed the biggest increase—from 9 percent in 1957 to 15 percent in 1961. The Christian Democratic Party grew out of the Conservative Party. In 1938 a group of young conservatives had left their party to form the National Falange (Falange Nacional). In 1957 the National Falange fused with the Social Christian Party (which had also seceded from the Conservatives) to form the Christian Democratic Party, whose program tended toward serious reforms in the archaic economic and social structures. The Communist Party regained strength peacefully through an alliance with the Socialist Party, which believed that election was not the only way to power and which rejected alliances with the non-Marxist left.

The Christian Democratic Party

At the end of Alessandri Rodríguez' rule the right-wing parties were so weakened that their electoral strength was practically cut in half in the 1965 elections; in order to remain on the political scene, they joined together to form the National Party. The centrist Radical Party also lost support. A common point existed between the Christian Democratic Party and the Marxist parties—the wish to weaken the old economic and political oligarchy and to try to rescue the country from its chronic underdevelopment by more decisive action in the agrarian sectors.

A period of change, 1964–73. In the election of 1964 the Christian Democratic candidate, Eduardo Frei Montalva, won 56 percent of the votes. Support from the right-wing parties helped him defeat the Marxist coalition.

The presidency of Frei Montalva. Frei's program, synthesized in the slogan "Revolution in Liberty," promised a series of reforms for developing the country by raising the incomes of the lower classes. To attain this aim, Frei and the Christian Democrats instituted a program of "Chileanization," by which the state took control of copper, Chile's principal resource, acquiring 51 percent of the shares of the large U.S. copper companies in Chile. They thus intended to increase incomes, with which they planned to permit industries to develop; they also planned a vast agrarian reform by which to reduce the imports of agricultural products. Frei also promised decisive state intervention and reform in banking. The Frei administration, at least during its first years, counted on strong support from the middle class. But the government alienated some of the middle class by trying also to obtain the support of the peasants and of the urban underemployed, until then on the margin of the political scene.

In 1967, with the support of the Socialist and Communist parties, an agrarian reform law was approved that enabled the government to expropriate uncultivated land and to limit the land that could be conserved by each owner. Peasant cooperatives were to be established on these lands, and the state was empowered to teach the peasants better farming techniques. Agrarian reform, however, proceeded slowly because of its costly emphasis on better housing and agricultural equipment and on an irrigation system. By 1970 about 5,000,000 acres had been expropriated.

Agrarian reforms

The socialist experiment. The reformist program of the Frei government gave poorer people the incentive to take an active role in political life. This increase in political participation brought about further radicalization not only of the Communist and Socialist parties but also of some of the Radicals and Christian Democrats. In 1969 this cluster of parties and left-wing groups formed the Popular Unity (Unidad Popular) coalition, proposing as its presidential candidate Salvador Allende Gossens, a Socialist and an avowed Marxist; he was elected president in 1970.

The Popular Unity program envisaged the eventual transition to socialism, which was to be accomplished through the end of domination of mining and finance by foreign capital, expanded agrarian reform, and more equal distribution of income favouring the poorer classes. The accomplishments of this program were responsible for the advance of Popular Unity in the municipal elections of 1971 and in the congressional elections of 1973.

Between 1970 and 1972, however, toleration of the Popular Unity government by the middle class declined as a consequence of difficulties in the economy, which featured a complex and not always consistent reorganization resulting from the nationalization of U.S.-owned copper mines—the main resource of economic production—and of a number of heavy industries. Difficulties in maintaining production levels were further augmented by boycotts on the side of foreign capital, mainly American, and the reduction of agricultural production as a consequence of agrarian reform. Inflation and stagnation of production were propitious to the growth and regrouping of the forces that opposed the socialist experiment. The oligarchy, the right-wing National Party, and the centre Christian Democrats finally joined their efforts and supported the antigovernment trends in the armed forces.

The military dictatorship, from 1973. On Sept. 11, 1973, the armed forces staged a coup d'état. Allende died during an assault on the presidential palace, and a junta

The Pinochet regime

composed of three generals and an admiral, with Gen. Augusto Pinochet Ugarte as president, was installed. At the outset the junta received the support of the oligarchy and of a sizable part of the middle-class. This support by moderate political forces, including many Christian Democrats, can be explained by their belief that a dictatorship represented a transitional stage necessary to restoring the status quo as it had been before 1970. Very soon they were to concede that the military officers in power had their own political objectives, including the repression of all left-wing and centre political forces. The Christian Democratic, National, and Radical Democracy parties were declared to be in "indefinite recess," and the Communists, Socialists, and Radicals were proscribed. In 1977 the traditional parties were dissolved, and a private enterprise economy was instated.

The policies of the military government, though encouraging the development of free enterprise and a new entrepreneurial class, caused unemployment, a decline of real wages, and, as a consequence, a worsening of the standard of living of the lower and middle classes. Conditions were complicated by a developing international economic crisis. In 1981 a new constitution, as well as an eight-year extension of Pinochet's presidential term, was approved after a tightly controlled plebiscite was held. The document included specific provisions for a transition to civilian government over the same eight-year period.

(M.A.Ca./P.W.D.)

Growing opposition to Pinochet's policies

Pinochet's economic policies called for a return to a free market system. Economic growth did not occur as expected; the national debt increased, the price of copper on the international market dropped, and inflation and unemployment rose. Several opposition parties, the Christian Democratic Party being the largest, formed a new centre-left coalition, the Democratic Alliance (Alianza Democrática; AD). Large-scale popular protests erupted after 1983. The Roman Catholic Church also began openly to support the opposition. In August 1984, 11 parties of the right and centre signed an accord, worked out by the Archbishop of Santiago, Raúl Cardinal Silva Henríquez, calling for elections to be scheduled before 1989. Additional pressure came from the United States and other countries that had supported Chile economically but now showed signs of impatience with Pinochet's rule and with the numerous reports of human rights violations attributed to his regime.

The economic and political climate continued to be volatile in the late 1980s, with increasing pressure for governmental change. Although Pinochet made occasional concessions, he showed little sign of relinquishing his control or relaxing his restrictive policies. On Oct. 5, 1988, however, in a constitutionally mandated plebiscite, voters rejected Pinochet, who had been chosen as the sole candidate for president by the junta in August. The first free elections since the 1973 coup were scheduled for December 1989.

In the presidential election, Christian Democrat Patricio Aylwin Azócar, leader of the Coalition of Parties for Democracy, won by a large margin over his closest opponent, Hernán Büchi Buc, a former finance minister and the government-endorsed candidate. The coalition also gained a majority in the lower chamber and nearly half the seats in the upper chamber. Aylwin, who took office in March 1990, supported Chile's free-market system but also emphasized social and political change. However, prior to Aylwin's election, Pinochet had secured legislation that allowed him to appoint several new Supreme Court justices and claim a lifetime senatorial seat; he also retained significant power as commander of the armed forces until his retirement from the military in 1998.

During the 1990s Chile had a generally negative balance of trade and modest economic growth. Moderate policies and increased civil liberties were promoted by Presidents Eduardo Frei, Jr., who led the Coalition of Parties for Democracy, and Ricardo Lagos, who was elected in 2000 as Chile's first socialist president since Allende.

In 1998 Chile became embroiled in an unprecedented controversy. Pinochet was detained while visiting London, because a Spanish judge requested his extradition in connection with the earlier torture of Spanish citizens in Chile. The case caused the United States and other countries to release documents relating to those who had "disappeared" in Chile under Pinochet's dictatorship; partly as a result, similar crimes committed in nearby countries also came to light. In January 2000 Pinochet won an appeal on medical grounds and returned home, but Chilean authorities continued to investigate numerous charges of earlier human rights abuses. (Ed.)

For later developments in the history of Chile, see the BRITANNICA BOOK OF THE YEAR.

China

China (in full People's Republic of China, Wade–Giles romanization Chung-hua Jen-min Kung-ho-kuo, Pinyin Zhonghua Renmin Gongheguo) is the largest of all Asian countries and has the largest population of any country in the world. Occupying nearly the entire East Asian landmass, it stretches for about 3,100 miles (5,000 kilometres) from east to west and 3,400 miles from north to south and covers an area of about 3,696,100 square miles (9,572,900 square kilometres). China is surpassed in area only by Russia and Canada.

China's land frontier is about 12,400 miles in length, and its coastline extends for some 8,700 miles. The country is bounded by Mongolia to the north; Russia and North Korea to the northeast; the Yellow Sea and the East China Sea to the east; the South China Sea to the southeast; Vietnam, Laos, Myanmar (Burma), India, Bhutan, and Nepal to the south; Pakistan to the southwest; and Afghanistan, Tajikistan, Kyrgyzstan, and Kazakstan to the west.

China has 33 administrative units directly under the central government; these consist of 22 provinces, five autonomous regions, four municipalities (Chungking, Peking, Shanghai, and Tientsin), and two special administrative regions (Hong Kong and Macau). The island province of Taiwan, which has been under separate administration since 1949, is discussed in the article TAIWAN. Peking (Beijing), the capital of the People's Republic, is also the major cultural, economic, and communications centre of the nation. Shanghai is the main industrial city and has rapidy emerging financial and commercial sectors; Hong Kong is China's leading financial and commercial centre and port.

Within China's boundaries exists a highly diverse and complex country. Its topography encompasses the highest and one of the lowest places on Earth, and its relief varies from nearly impenetrable mountainous terrain to vast coastal lowlands. China's climate ranges from dry, desert-like conditions in the northwest to tropical monsoon in the southeast, and the country has the greatest contrast in temperature between its northern and southern borders of any nation in the world.

The diversity of both China's relief and its climate has resulted in one of the world's widest arrays of ecological niches, and these niches have been filled by a vast number of plant and animal species. Indeed, practically all types of Northern Hemisphere plants, except those of the polar tundra, are found in China, and, despite the continuous inroads of humans over the millennia, China still is home to some of the world's most exotic animals.

Probably the single most identifiable characteristic of China to the people of the rest of the world is the size of its population. More than one-fifth of mankind is of Chinese nationality. The great majority of the population is Chinese (Han), and thus China is often characterized as an ethnically homogeneous country; but few countries have as wide a variety of indigenous peoples as does China. Even among the Han there are cultural and linguistic differences between regions; for example, the only point of linguistic commonality between two individuals from different parts of China may be the written Chinese language. Because China's population is so enormous, the population density is also often thought to be uniformly high, but vast areas of China are either uninhabited or sparsely populated.

With more than 4,000 years of recorded history, China is one of the few existing countries that also flourished economically and culturally as one of the world's earliest civilizations. Indeed, despite the political and social upheavals that frequently have ravaged the country, China is unique among nations in its longevity and resilience as a discrete politico-cultural unit. Much of China's cultural development has been accomplished with relatively little outside influence, the introduction of Buddhism from India constituting a major exception. Even when the country was penetrated by such "barbarian" peoples as the Manchus, these groups soon became largely absorbed into the fabric of Han Chinese culture.

This relative isolation from the outside world made possible over the centuries the flowering and refinement of the Chinese culture, but it also left China ill prepared to cope with that world when, from the mid-19th century, it was confronted by technologically superior foreign nations. There followed a century of decline and decrepitude, as China found itself relatively helpless in the face of a foreign onslaught. The trauma of this external challenge became the catalyst for a revolution that began in the early 20th century against the old regime and culminated in the establishment of a Communist government in 1949. This event reshaped global political geography, and China has since come to rank among the most influential countries in the world.

Central to China's administrative, political, cultural, and economic character is the province, or *sheng*. The provinces are traceable in their current form to the T'ang dynasty (AD 618–907). Over the centuries, provinces gained in importance as centres of political and economic authority and increasingly became the focus of regional identification and loyalty. Provincial power reached its peak in the first two decades of the 20th century, but since the establishment of Communist rule in China this power has been curtailed by a strong central leadership in Peking. Nonetheless, while the Chinese state has remained unitary in form, the vast size and population of China's provinces—which are comparable to large and midsize nations—dictate their continuing importance as a level of subnational administration.

This article first discusses the physical and human geography of the country, followed by the history of China from prehistory to the present day. Finally, the 33 administrative units, organized by region, are treated individually in detail. The province-level municipalities of Chungking, Peking, Shanghai, and Tientsin are listed in the outline below in their respective regions, but the discussions of these cities appear in the *Macropædia* articles CHUNGKING (CHONGQING), PEKING (BEIJING), SHANGHAI, and TIENTSIN (TIANJIN). The Hong Kong and Macau special administrative regions, also listed in the outline, are discussed in the articles HONG KONG and (in the *Micropædia*) MACAU.

The article is divided into the following sections:

PHYSICAL AND HUMAN GEOGRAPHY

The land

RELIEF

The relief of China is high in the west and low in the east; consequently, the direction of flow of the major rivers is generally eastward. The surface may be divided into three relief steps, or levels. The first level is represented by the Plateau of Tibet, which is located in both the Tibet Autonomous Region and the province of Tsinghai and which, with an average elevation of well over 13,000 feet (4,000 metres) above sea level, is the loftiest highland area in the world. The western part of this region, the Ch'iang-t'ang, has an average height of 16,500 feet and is known as the "roof of the world."

Three relief levels

The second step lies to the north of the Kunlun and Ch'i-lien mountains and, farther south, to the east of the Ch'iung-lai and Ta-liang mountains. There the mountains descend sharply to between 6,000 and 3,000 feet, after which basins intermingle with plateaus. This step includes the Mongolian Plateau, the Tarim Basin, the Loess Plateau (loess is wind-deposited yellow-gray dust), the Szechwan Basin, and the Yunnan-Kweichow highland region.

The third step extends from the east of the Ta-lou, T'ai-hang, and Wu mountain ranges and from the eastern perimeter of the Yunnan-Kweichow highland region to the China Sea. Almost all of this area is made up of hills and plains lying below 1,500 feet.

The most remarkable feature of China's relief is the vast extent of its mountain chains; the mountains, indeed, have exerted a tremendous influence on the country's political, economic, and cultural development. At a rough estimate, about one-third of the total area of China consists of mountains. China has the world's highest mountain and the world's highest and largest plateau, in addition to possessing extensive coastal plains. The five major landforms—mountain, plateau, hill, plain, and basin—are all well represented. China's complex natural environment and rich natural resources are closely connected with the varied nature of its relief.

The topography of China is marked by many splendours. Mount Everest (Chu-mu-lang-ma Feng; 29,035 feet [8,850 metres] high), on the border between China and Nepal, is the highest peak in the world. By contrast, the lowest part of the Turfan Depression in the Uighur Autonomous Region of Sinkiang—Lake Ai-ting—is 505 feet (154 metres) below sea level. The coast of China contrasts greatly between South and North. South of the bay of Hang-chou, the coast is rocky and indented with many harbours and

MAP INDEX

Entries in this index are transcribed from Chinese in the Pinyin romanization system. This system was adopted by the Chinese government beginning in 1956 and since 1979 has been the officially prescribed system in publishing for English-speaking countries. In addition, the index contains a number of cross-references from Pinyin to certain conventional English names and spellings used in the *Britannica*. In this index and the supplement that follows it, the term "local" designates a name used locally but not administratively.

Political subdivisions

Cities and towns

Physical features and points of interest

INDEX SUPPLEMENT

This index supplement shows Pinyin equivalents for geographic names rendered in conventional spelling or in the Wade-Giles romanization system. Some English-language reference works, including the *Macropædia* and the *Micropædia*, use conventional spellings for Chinese political subdivisions and a combination of conventional and Wade-Giles spellings for cities and towns as well as physical features and points of interest. The supplement thus serves as a bridge between this usage and the Pinyin on the map.

Conventional/Wade-Giles	Pinyin

offshore islands. To the north, except along the Shantung and Liaotung peninsulas, the coast is sandy and flat.

The influence of relief on historic development

China's physical relief has dictated its development in many respects. The civilization of China originated in the southern part of the Loess Plateau, and from there it extended outward until it encountered the combined barriers of relief and climate. The long, protruding corridor, commonly known as the Kansu, or Hosi, Corridor, illustrates this fact. South of the corridor is the Plateau of Tibet, which was too high and too cold for the civilization of China to gain a foothold. North of the corridor is the Gobi Desert, which also formed a barrier. Consequently, Chinese civilization was forced to spread along the corridor, where melting snow and ice in the Ch'i-lien Mountains provided water for oasis farming. The westward extremities of the corridor became the meeting place of the ancient East and West.

Thus, for a long time the ancient political centre of China was located along the lower reaches of the Huang Ho (Yellow River). Because of topographical barriers, however, it was very difficult for the central government, except when represented by an unusually strong dynasty, to gain complete control over the entire country. In many instances the Szechwan Basin—an isolated region in southwestern China, about twice the size of Scotland, that is well protected by high mountains and is self-sufficient in agricultural products—became an independent kingdom. A comparable situation often arose in the Tarim Basin in the northwest. Linked to the rest of China only by the Kansu Corridor, this basin is even remoter than the Szechwan, and, when the central government was unable to exert its influence, oasis states were established; only the three strong dynasties—the Han (206 BC–AD 220), the T'ang (AD 618–907), and the Ch'ing, or Manchu (1644–1911/12)—were capable of controlling the region.

Apart from the three altitudinal zones already men-

tioned, it is possible—on the basis of geologic structure, climatic conditions, and differences in geomorphologic development—to divide China into three major topographical regions: the eastern, northwestern, and southwestern zones. The eastern zone is a region shaped by the rivers, which have eroded landforms in some parts and have deposited alluvial plains in others; its climate is monsoonal (characterized by seasonal rain-bearing winds). The northwestern region is arid and eroded by the wind; it forms an inland drainage basin. The southwest is a cold, lofty, and mountainous region containing intermontane plateaus and inland lakes.

The three basic regions may be further subdivided into second-order geographic divisions. The eastern region contains 10 of these, the southwest contains two, and the northwest contains three. Below is a brief description of each division.

The eastern region. *The Manchurian Plain.* The Manchurian Plain (also known as the Northeast Plain and the Sung-liao Plain) is located in China's Northeast, the region formerly known as Manchuria. An undulating plain split into northern and southern halves by a low divide rising from 500 to 850 feet, it is drained in its northern part by the Sungari River and tributaries and in its southern part by the Liao River. Most of the area has an erosional rather than a depositional surface, but it is covered with a deep soil. The plain has an area of about 135,000 square miles. Its basic landscapes are forest-steppe, steppe, meadow-steppe, and cultivated land; its soils are rich and black, and it is a famous agricultural region. The river valleys are wide and flat with a series of terraces formed by deposits of silt. During the flood season the rivers inundate extensive areas.

The Ch'ang-pai Mountains. To the southeast of the Manchurian Plain is a series of ranges comprising the Ch'ang-pai, Chang-kuang-ts'ai, and Wan-ta mountains, which in Chinese are collectively known as the Ch'ang-pai Shan, or "Forever White Mountains"; broken by occasional open valleys, they reach altitudes mostly between 1,500 and 3,000 feet. In some parts the scenery is characterized by rugged peaks and precipitous cliffs. The highest peak is the volcanic cone of Mt. Pai-t'ou (9,003 feet), which has a beautiful crater lake at its snow-covered summit. As one of the major forest areas of China, the region is the source of many valuable furs and famous medicinal herbs. Cultivation is generally limited to the valley floors.

The North China Plain. Comparable in size to the Manchurian Plain, most of this plain lies at heights below 150 feet, and the relief is monotonously flat. It was formed by enormous sedimentary deposits brought down by the Huang Ho and Huai River from the Loess Plateau; the Quaternary deposits alone (*i.e.,* those from 10,000 to 2,500,000 years old) reach thicknesses of 2,500 to 3,000 feet. The river channels, which are higher than the surrounding locality, form local water divides, and the areas between the channels are depressions in which lakes and swamps are found. In particularly low and flat areas, the underground water table often fluctuates from five to six and a half feet, resulting in the formation of meadow swamp and, in some places, saline soils. A densely populated area that has long been under settlement, the North China Plain has the highest proportion of land under cultivation of any region in China.

Formation of the plain

The Loess Plateau. This plateau forms a unique region of loess-clad hills and barren mountains situated between the North China Plain and the deserts of the west. In the north, the Great Wall of China forms the boundary, while the southern limit is the Tsinling Mountains, in Shensi Province. The average altitude of the surface is between 4,000 and 5,000 feet, but individual ranges of bedrock are higher, reaching 9,285 feet in the Liu-p'an Mountains. Most of the plateau is covered with loess to thicknesses of 150 to 650 feet. In northern Shensi Province and eastern Kansu Province the loess may reach a thickness of 800 feet. The loess is particularly susceptible to erosion by water; ravines and gorges are found crisscrossing the plateau. It has been estimated that ravines cover approximately one-half of the entire region, with erosion reaching depths of 300 to 650 feet.

The Shantung Hills. These hills are basically composed of Archean (Early to Middle Precambrian) crystalline shales and granites and of Lower Paleozoic sedimentary rocks (*i.e.,* between 395,000,000 and 570,000,000 years old). Faults have played a major role in creating the present relief, and, as a result, many hills are horsts (blocks of the Earth's crust uplifted along faults), while the valleys have been formed by grabens (blocks of the Earth's crust that have been downthrown along faults). The Chiao-lai Plain divides this region into two parts. The eastern part is lower, lying at altitudes averaging less than 1,500 feet, with only certain peaks and ridges rising to 2,500 feet and (rarely) to 3,000 feet, and only one mountain, Mt. Lao, reaching a height of 3,707 feet. The western part is slightly higher; the highest peak is Mt. T'ai (5,026 feet), which is sacred as a symbol of the divine election of the ruling house of China. The Shantung Hills meet the sea along a bold and rocky shoreline.

The Tsinling Mountains. The Tsinling Mountains in Shensi Province are the greatest chain of mountains east of the Plateau of Tibet. The mountain chain consists of a high and rugged barrier extending from Kansu to Honan; geographers use a line between the chain and the Huai River to divide China proper into two parts—North and South. The altitude of the mountains varies from 3,000 to 10,000 feet. The western part is higher, with the highest peak, Mt. T'ai-pai, rising to 13,474 feet. The Tsinling Mountains consist of a series of parallel ridges, all running slightly south of east, separated by a maze of ramifying valleys whose canyon walls often rise sheer to a height of 1,000 feet above the valley streams.

Division between North and South China

The Szechwan Basin. This basin (also known as the Red Basin) is one of the most attractive geographical regions of China. The basin is surrounded by mountains, which are higher in the west and north. Protected against the penetration of cold northern winds, the basin is much warmer in the winter than are the more southerly plains of southeast China. Except for the Ch'eng-tu Plain, the region is very hilly. In the eastern half of the basin are numerous folds, forming a series of ridges and valleys that trend northeast to southwest. The lack of arable land has obliged farmers to cultivate the slopes of the hills, on which they have built terraces that frequently cover the slopes from top to bottom. The terracing has slowed down the process of erosion and has made it possible to cultivate additional areas by using the steeper slopes—some of which have grades up to 45° or more.

The Southeast Mountains. Southeastern China is bordered by a rocky shoreline backed by picturesque mountains. In general, there is a distinct structural and topographic trend from northeast to southwest. The higher peaks may reach altitudes of 5,000 to 6,500 feet. The rivers are short and fast-flowing and have cut steep-sided valleys. The chief areas of settlement are on narrow strips of coastal plain where rice is produced. Along the coast there are numerous islands, where the fishing industry is well developed.

Plains of the Middle and Lower Yangtze. East of I-ch'ang, in Hupeh Province, a series of plains of uneven width are found along the Yangtze River, or Ch'ang Chiang. The plains are particularly wide in the delta area and in places where the Yangtze receives its major tributaries—including large areas of lowlands around the lakes of Tung-t'ing, P'o-yang, T'ai, and Hung-tse, which are hydrologically linked with the Yangtze. The region is an alluvial plain, the accumulation of sediment laid down by the rivers throughout long ages. There are a few isolated hills, but in general the land is level, lying mostly below 150 feet. Rivers, canals, and lakes form a dense network of waterways. The surface of the plain has been converted into a system of flat terraces, which descend in steps along the slopes of the valleys.

The Nan Mountains. The Nan Mountains (in Chinese Nan Ling) are composed of many ranges of mountains running from northeast to southwest. These ranges form the watershed between the Yangtze to the north and the Pearl River (Chu Chiang) to the south. The main peaks along the watershed are above 5,000 feet, and some are more than 6,500 feet. But a large part of the land to the

south of the Nan Mountains is also hilly; flatland does not exceed 10 percent of the total area. The Pearl River Delta is the only extensive plain in this region and is also the richest part of South China. The coastline is rugged and irregular, and there are many promontories and protected bays, including that of Hong Kong. The principal river is the Hsi River, which rises in the highlands of eastern Yunnan and southern Kweichow.

The southwest. *The Yunnan–Kweichow highland region.* This region comprises the northern part of Yunnan and the western part of Kweichow; its edge is highly dissected. Yunnan is more distinctly a plateau and contains larger areas of rolling uplands than Kweichow, but both parts are distinguished by canyon-like valleys and precipitous mountains. The highest elevations lie in the west, where Mt. Tieh-chi'ang rises to 12,080 feet. In the valleys of the major rivers, elevations drop to 1,300–1,600 feet. Particularly sharp differences in elevation and the greatest ruggedness of relief occur in the western part of the region, in the gorges of the large rivers. In the eastern part, karst processes (creating sinks, ravines, and underground streams in the limestone landscape) have developed very strongly. Scattered throughout the highlands are small lake basins, separated by mountains.

The Plateau of Tibet. This great massif occupies about one-fourth of the whole country. A large part of the plateau lies at elevations above 13,000–15,000 feet. The border ranges of the plateau are even higher, with individual peaks rising to heights of 23,000–26,000 feet. The interior slopes of these border mountains, as a rule, are gentle, while the exterior slopes are very steep. In its eastern and southern periphery, great rivers—such as the Yangtze, Huang, Mekong, Salween, Indus, and Brahmaputra—find their sources. Only in the low valleys, chiefly along the Brahmaputra Valley, are there centres of human settlement.

The Tsaidam Basin

The Tsaidam Basin is the largest, as well as the lowest, basin in the Plateau of Tibet. The broad northwestern part of the basin lies at elevations from approximately 8,800 to 10,000 feet; the narrow southeastern part lies between about 8,500 and 8,800 feet. Within the basin there is a predominance of gravel, sandy and clay deserts, semideserts, and salt wastes.

The northwest. *The Tarim Basin.* North of the Plateau of Tibet and at the much lower level of about 3,000 feet lies the Tarim Basin. It is hemmed in by great mountain ranges: the Tien Shan ("Celestial Mountains") on the north, the Pamirs on the west, and the Kunlun Mountains on the south. From these heights glacier-fed streams descend, only to lose themselves in the loose sands and gravels of the Takla Makan Desert, which occupies the centre of the basin. The Takla Makan is one of the most barren of the world's deserts; only a few of the largest rivers, such as the Tarim and Ho-t'ien (Khotan), cross the desert, but even their flow is not constant, and they have water throughout their entire courses only during the flood period. The area of the basin is about 215,000 square miles, and its elevations are from 2,500 to 4,600 feet above sea level. Its surface slants to the southeast, where the Lop Nor (a salt-encrusted lake bed) is situated.

The Dzungarian Basin. North of the Tarim Basin is another large depression, the Dzungarian. It is enclosed by the Tien Shan on the south, while to the northeast it is cut off from the Mongolian People's Republic by the Altai Mountains. The surface of the basin is flat, with a gentle slope to the southwest. The larger portion of the land lies at elevations between 1,000 and 1,500 feet, and in the lowest part the elevation drops to 620 feet. In general the main part of the basin is covered by a broad desert with barchans (crescent-shaped sand dunes that move); only in certain parts are dunes retained by vegetation.

The Tien Shan. The Chinese part of the Tien Shan consists of a complex system of ranges and depressions in which two major groups of ranges—the northern and southern—may be distinguished. They are separated by a strip of intermontane depressions that is broken up by the interior ranges. Ancient metamorphic rock (formed under heat and pressure) constitutes the larger portion of the ranges in the interior zone; Paleozoic (from 225,000,000 to 570,000,000 years old) sedimentary and igneous sedimentary beds form its northern and southern chains, while Mesozoic (from 65,000,000 to 225,000,000 years old) sandstones and conglomerates fill the intermontane depressions in the interior zone and constitute the foothill ridges. The height of the main chains of the eastern Tien Shan is between 13,000 and 15,000 feet, with individual peaks exceeding 16,000 feet; the interior chains reach 14,500 feet. In the western part, where there is adequate precipitation, large glaciers are formed, reaching a length of more than 20 miles. Large rivers with much water, such as the T'e-k'o-ssu River and its tributaries, begin their courses there. With predominantly alpine meadow steppe, this area is one of the best grazing lands of China.

Tien Lake at the foot of the Po-ko-ta Mountains in the eastern Tien Shan, Uighur Autonomous Region of Sinkiang.
K Scholz—Shostal Assoc

DRAINAGE

China has more than 50,000 rivers with individual drainage areas of more than 40 square miles. Of the total annual runoff (amount of water they carry away) about 95 percent drains directly into the sea (more than 80 percent into the Pacific Ocean, 12 percent into the Indian Ocean, and less than 1 percent into the Arctic Ocean) and 5 percent disappears inland.

The principal rivers

The three principal rivers of China, all of which flow generally from west to east, draining into the China Sea, are the Huang, the Yangtze, and the Hsi. The Huang Ho, which rises in the Kunlun Mountains, is the northernmost of the three; it drains into the Po Hai (Gulf of Chihli), north of the Shantung Peninsula. The Yangtze, the longest river in the country, rises in the Tibetan Highlands and flows across central China, draining into the East China Sea north of Shanghai. The Hsi River, the southernmost of the three, rises in the Yunnan–Kweichow highlands and empties into the South China Sea via the Pearl River Delta, at Canton.

The distribution of surface water in China is extremely uneven. Only a small part of the country has enough water year-round. Much of the country has abundant runoff but only during the rainy summer, when enormous surpluses of water are received. From the southeast to the northwest, the surface water decreases as mountainous

features increase. A vast area of the northwest lacks water throughout the year. North China (north of the Tsinling Mountains–Huai River line), with its flat relief and long history of agriculture, contains almost two-thirds of China's cultivated land; paradoxically, because of scanty and erratic precipitation, the average annual runoff in the North accounts for only about one-sixth of the total for the country as a whole.

The mountains of the southeast and the mountainous Hai-nan Island have the most abundant surface water. Over the year they receive more than 60 inches (1,500 millimetres) of precipitation (in some places even more than 80 inches), of which almost two-thirds constitutes the runoff, so that a dense drainage network has developed. The amount of runoff is highest in the southeast, exceeding 40 inches. It gradually diminishes toward the west and north, so that in the true deserts of the northwest it is usually less than 0.4 of an inch. The arid climate of the northwest is reflected in the landscape of the dry steppes, which is characterized by richer grasses in the east, while in the west the landscape gradually changes to bare deserts.

In the lower reaches of the Yangtze, the Pearl River Delta, and the Ch'eng-tu Plain a dense network of waterways has been developed. In the North China Plain and the Manchurian Plain most of the rivers have a linear flow, and tributaries are few and unconnected. In the inland drainage area there are very few rivers because of scanty precipitation. Extensive areas such as the Tarim Basin and northeastern Kansu Province are often completely devoid of runoff. In these regions the rivers depend upon melted snow and ice; in consequence, they are mostly small and are found only in mountains and mountain foothills. As they drain farther and farther away from the mountains, most of them eventually disappear in the desert, while some form inland lakes. Because the northern part of the Plateau of Tibet is a cold desert, the rate of evaporation is slow, so that a denser network of rivers has developed; most of these, however, run into glaciated depressions, forming numerous lakes.

SOILS

Because of its vast and diverse climatic conditions, China has a wide variety of soils. Indeed, all the soils of the Eurasian continent, except the soils of the tundra and the highly leached podzolic-gley soils of the northern taiga, are found in China. As a result of the climatic differences between the drier and cooler North and the wetter and hotter South, soils may be grouped into two classifications. Generally speaking, the soils north of the Tsinling Mountains–Huai River line are pedocals (calcareous) and are neutral to alkaline in reaction; those south of this line are pedalfers (leached noncalcareous soils), which are neutral to acid.

Apart from the great plateaus and high mountains to the southwest, marked soil zones are formed in China according to differences in climate, vegetation, and distance from the sea. The east and southeast coastal region is covered by the forest zone associated with a humid and semihumid climate, while the north and northwest inland regions belong mostly to the steppe zone, as well as to the semidesert and desert zone associated with a semiarid and arid climate. Between these two broad soil zones lies a transitional zone—the forest-steppe zone, where forest soils merge gradually with steppe soils.

Between the pedocals of the North and the pedalfers of the South lie the neutral soils. The floodplain of the Yangtze below the Three Gorges, where the river cuts through the Wu Mountains to empty onto the Hupeh Plain, is overlain with a thick cover of noncalcareous alluvium. These soils, sometimes classified as paddy (rice-growing) soils, for the most part are exceedingly fertile and of good texture. The paddy soil is a unique type of cultivated soil; it has been formed over a long period of time under the specific conditions of rice cultivation.

Along the coast of North China are belts of saline and alkaline soil. They are associated with a combination of poor drainage and aridity, where the rainfall is insufficient either to dissolve or to carry away the salts in solution.

The adverse effects of nature on the soil have been further intensified by centuries of concentrated cultivation, which has resulted in an almost universal deficiency of nitrogen and of organic matter. The shortage of organic matter is due primarily to the habitual use by farmers of crop stalks and leaves for livestock feed and fuel. The animal manure and night soil used for fertilizer contain too small an amount of organic matter to compensate for the loss of nutrients in the soil. The soils are also often deficient in phosphorus and potassium, but these deficiencies are neither so widespread nor so severe as that of nitrogen.

At one time, half of the territory of China may have been covered by forests, but now less than one-tenth of the country is forested. Extensive forests in central and southern China were cleared for farmlands, resulting in the inevitable erosion of soils from the hillsides and their deposition in the valleys. Farmers have constructed level terraces, supported by walls, in order to hold back water for rice fields, thus effectively controlling erosion. Wherever elaborate terraces have been built, soil erosion is virtually absent, and stepped terraces have become one of the characteristic features of the rural landscape.

Soil erosion

Excessive grazing and destruction of the grass cover also have resulted in soil removal. With the valuable crumb structure broken down and porosity lost, the topsoil is easily washed away through erosion in the rainy season; if the region happens to be a dry one, the wind produces the same effect. The Loess Plateau, constantly buffeted by rain and wind, is especially vulnerable to soil erosion, which results in a distinctive landscape. Steep-sided gullies, some of which may be several hundred feet deep, cut the plateau into fantastic relief. The damage done by heavy rain in summer is caused not only by the loss of topsoil but also by the frequent flooding of silt-laden rivers.

(C.-S.Ch./K.G.L./Ed.)

CLIMATE

The air masses. China lies in Asia, the world's largest continent, and faces the Pacific, the world's largest ocean. Between the Pacific and China's part of Asia, there is a seasonal movement of air masses. The polar continental air mass, originating in Siberia, dominates a large part of China during the winter, while the tropical Pacific air mass exerts its influence during the summer. The sharply varied climatic conditions prevailing in summer and in winter are a direct result of the interaction of these two air masses, which are entirely different in nature.

The Siberian air mass, which is quite stable, is extremely cold and dry and often has marked layers of temperature inversion. After crossing the Mongolian Plateau, the air mass spreads southward and begins to invade North China, where it undergoes a series of rapid changes; its temperature rises slightly, and its stability decreases. During the day it may be quite warm, but at night or in shaded places the cold is often unbearable. In general, the diurnal (daily) range of temperature is more than 18° F (10° C); in extreme cases, it may exceed 45° F (25° C). Because North China is affected by this air mass most of the time, it is dry, with clear weather and an abundance of sunshine during the winter months.

The prevailing winter wind blows from November through March; it changes direction as it moves to the south. In northern and northeastern China its direction is from the northwest, in eastern China it comes from the north, and on the southeastern coasts it is from the northeast. The height of the winter wind belt usually does not exceed 13,000 feet. As it moves to the south, the height decreases; in Nanking it is about 6,500 feet, and in South China it is less than 5,000 feet. The Tsinling Mountains become an effective barrier to the advance of the cold waves to the south, particularly in the western section, where the average altitude of the mountains is mainly between 6,500 and 9,000 feet.

In China the tropical Pacific air mass is the chief source of the summer rainfall. When it predominates, it may cover the eastern half of China and penetrate deep into the border areas of the Mongolian Plateau and onto the eastern edge of the Plateau of Tibet. In summer the Siberian air mass retreats to the western end of Mongolia, although it occasionally extends southward and sometimes

Effects of the tropical Pacific air mass

may reach the Huai River Valley, which constitutes a battleground between the tropical Pacific and Siberian air masses in summer.

The movement of the two air masses is of immense significance to the climate of central and North China. In summer, when the tropical air mass predominates, the frontal zone between the two shifts northward; as a result, North China receives heavier rainfall. When the southeastern monsoon slackens, however, the frontal zone moves southward, and central China receives more rainfall, as a result of which floods may occur. The activity of the tropical Pacific air mass in winter is confined to the southeast coastal areas; during this season, therefore, drizzle frequently occurs in the hilly areas south of the Nan Mountains, and fog often appears in the morning.

Besides these two air masses, three other air masses also play their parts in the making of the climate of China. These are the equatorial continental air mass (a highly unstable southwest monsoon), the polar maritime air mass, and the equatorial maritime air mass. Furthermore, because China is a vast country with complex topography, the interaction between the air masses and relief produces many different types of climate.

The temperature pattern

Temperature. Temperatures generally decrease from south to north. The mean annual temperature is above 68° F (20° C) in the Pearl River Valley. It decreases to between 59° and 68° F (15° and 20° C) in the middle and lower reaches of the Yangtze, to about 50° F (10° C) in North China and the southern part of Sinkiang, and to 41° F (5° C) in the southern area of the Northeast, the northern part of Sinkiang, and places near the Great Wall. It drops below 32° F (0° C) in the northern part of Heilungkiang. The annual range of temperature between the extreme south and north is about 86° F (48° C). With few exceptions, January is the coldest month, and July is the hottest.

South of the Tsinling Mountains–Huai River line, the mean January temperature increases progressively, rising from 32° F to 72° F (22° C) on the southern coast of Hainan Island. Snow rarely falls, and the rivers do not freeze. North of this line, the temperature drops from 32° F to −18° F (−28° C) in the northern part of Heilungkiang.

In April the mean temperature is above 32° F for the whole of China with the exception of the extreme north of Heilungkiang. During this time the mean temperature for the Manchurian Plain is between 36° and 46° F (2° and 8° C), and for the extensive plain between Peking and Shanghai it is between 54° and 59° F (12° and 15° C). South of the Nan Mountains the mean temperature is well over 68° F (20° C). Along the coast of southern Kwangtung, willows start to bud in late January, but in Peking the budding of willows comes as late as early April.

In summer the range of temperature between North and South China is quite small. In July the difference in temperature between Canton and Peking is only about 5° F (3° C), and the isotherms in July are roughly parallel to the coastline. In July the isotherm of 82° F (28° C) marks an extensive area. The hottest places in China are to be found along the valleys of the Middle and Lower Yangtze. The mean July temperature of Nan-ch'ang and Ch'ang-sha is well over 84° F (29° C), and in many years it is above 86° F (30° C).

In North China autumn is generally cooler than spring; the mean October temperature in Peking is about 55° F (13° C), and in April the mean temperature is about 57° F (14° C). In South China the reverse is true. The mean October temperature in Canton is 75° F (24° C); in April the mean temperature is only about 70° F (21° C).

The middle and lower reaches of the Huang Ho are the areas where China's civilization and agriculture first developed. There the seasonal rhythm is well marked, and the duration of each season is evenly spaced. In other parts of China, however, there are variations among different regions in the duration, as well as in the starting and closing dates, of each season. In northern Heilungkiang summer is nonexistent, while in southern Kwangtung there is no winter. In K'un-ming, on the Yunnan plateau, the climate is mild throughout the year, and summer and winter are very brief.

In general, south of the Tsinling Mountains–Huai River line the mean daily temperature seldom falls below freezing, so that farming can be practiced all through the year. In the Yangtze Valley two crops a year are usually grown, but north of the Great Wall only one crop a year is grown.

Rainfall. Rainfall in China generally decreases from the southeast to the northwest. The annual precipitation of certain places along the southeastern coast amounts to more than 80 inches. The Yangtze Valley receives about 40 inches. Farther north, in the Huai River Valley the annual rainfall decreases to 30 inches. In the lower reaches of the Huang Ho only 20 inches of precipitation are received annually. The Northeast obtains much more precipitation than the North China Plain, where along the Southeast Mountains as much as 40 inches are received.

The southeast monsoon loses much of its moisture by the time it reaches the northern part of the Loess Plateau, where the annual precipitation is reduced to between 12 and 20 inches. Northwest of a line linking the Greater Khingan, Yin, Lang, Ch'i-lien, and A-erh-chin ranges the annual precipitation is less than 10 inches. This is because these regions are far from the sea, and the southern monsoon is prevented from reaching them by high mountains; only grasslands, therefore, are found there. In western Inner Mongolia, the Kansu Corridor, and the Tarim Basin, the annual precipitation is even less than four inches. These are areas of true desert, where sometimes not a single drop of rain is received for several years.

The Dzungarian Basin and the I-li Valley of northern Sinkiang are open to the influences of the westerlies; precipitation there is heavier. The precipitation of the Plateau of Tibet, like that of China as a whole, decreases from southeast to northwest. The valleys in the southeastern part of the plateau receive more than 40 inches of precipitation, while the eastern edge of the plateau receives 20 inches annually. But in the enclosed basin in the north—the Tsaidam—the annual precipitation is only four to 10 inches.

The high variability of rainfall is another characteristic of the climate of China. Usually, the less the rainfall, the greater the variability; this fact has a close connection with the high frequency of drought and flood in China. Spring rain is of immense significance to farming in China; unfortunately, spring is the season with the highest variability. In South China the variability exceeds 40 percent, along the Yangtze it is about 45 percent, and in North China it is more than 50 percent. The variability of a very large area in North China exceeds 70 percent in some places; east of Peking, for example, the rainfall variability in spring may even exceed 80 percent, as it also does in the central parts of the Yunnan–Kweichow highlands.

Rain falls mostly in the summer months, when plants need water the most. This is an important asset for farmers, but the rainfall in summer is usually too intense. In July, when the frontal zone shifts northward, cyclones (circulation of winds around centres of low atmospheric pressure) are much more active in North China than in South China, and North China begins to receive heavier rainfall. More than half of the North China Plain records eight-tenths of an inch of daily rainfall. In some places, as much as an inch or more may fall daily. During this time areas south of the Yangtze are covered by the tropical Pacific air mass, so that the weather becomes comparatively stable, and the amount of rainfall usually decreases, while the average rainfall intensity is less than that of June; a large area receives less than six-tenths of an inch. The intensity of August rainfall is in general less than that of July.

In the southeastern coastal regions, around Fu-chou and Swatow, the maximum daily rainfall may even approach 12 inches. This fact is clearly related to the high frequency of typhoons (tropical cyclones) striking this part of the coast, usually during the period from May to November; July, August, and September are the three months when typhoons are the most frequent.

Typhoons

In May typhoons usually strike the coast south of Swatow. Later in June they shift northward, arriving between Swatow and Wen-chou, and after July they invade areas north of Wen-chou. August has the highest frequency

of typhoon invasions, when more than one-third of the typhoons reaching China arrive. After September the frequency of typhoons decreases, and the pattern again shifts southward. In October typhoons usually land south of Wen-chou; the late typhoons arriving in November and December strike south of Swatow.

PLANT AND ANIMAL LIFE

Plant life. Types of natural vegetation and their floristic composition are extremely diverse. The total number of seed plants in China is about 30,000 species, representing 2,700 genera; more than 200 of these genera are restricted to China. There are about 2,500 species of forest trees, and, among flowering plants, 95 percent of the known woody group are to be found. Many of them are trees of economic importance, such as tung trees, camphor trees, lacquer trees, star anise (which yields an oil used as a flavouring additive), and privet.

Contributing to the variety and intermixture of tropical and temperate plants in China are such factors as the lack of insurmountable topographic barriers, such as large stretches of desert, between the tropical, temperate, and semifrigid zones; wind systems that alternate in winter and summer; and the frequent occurrence of cyclones. If, for example, the vegetation of Heilungkiang province in the North and Kwangtung province in the South are compared, it is hardly possible to find a single common plant species, with the exception of certain weeds. In the taiga of the northern border of China or in the high mountains, on the other hand, there are many plant species that are also found in the lands within the Arctic Circle, while in the Chinese tropics there are species that also grow south of the Equator. From the ecological point of view, the tropical forests of South China, however, do not in general differ greatly from those of Indonesia and other Southeast Asian countries, while the desert and steppe vegetation of northwestern China is closely akin to that found in Mongolia or to that in Kazakstan. Furthermore, the Chinese taiga terrain of the frontier area adjoining Russia in no way differs from that of Siberia.

Traveling in China, one may encounter practically all types of natural vegetation indigenous to the Northern Hemisphere, with the exception only of that of the polar tundra. There are mangrove swamps along the shores of the South China Sea; rain forests on Hai-nan Island and in the south of Yunnan; and deserts, steppes, meadows, and savannas, as well as regions where tropical and temperate coniferous, broad-leaved evergreen, and deciduous plants prevail.

In accordance with the character of the vegetation, China may be divided—roughly along a diagonal from the southwest to the northeast—into two sharply different parts: the dry northwest and the humid southeast. The tropical area, adjoining the humid southeast, is geographically related more to Southeast Asia.

In the northwest, where desertlike conditions prevail, are vast areas of sparse drought-resistant vegetation; within these areas in the low-lying land and depressions are patches of salt-tolerant plants, notably in the Dzungarian, Tsaidam, and Gobi regions. Skirting the southern edge of the Gobi is a wide belt of grassland. (C.-S.Ch.)

Rare species

Animal life. Profusion of vegetation and a variety of relief have fostered the development of a great diversity of animal life and have permitted the survival of animals that elsewhere are extinct. Notable among such survivals are the great paddlefish of the Yangtze, the small species of alligator in eastern and central China, and the giant salamander (related to the Japanese giant salamander and the American hellbender) in western China. The diversity of animal life is perhaps greatest in the ranges and valleys of Tibet and Szechwan, to which region the giant panda is confined. The takin, or goat antelope, numerous species of pheasants, and a variety of laughing thrushes are to be found in all the Chinese mountains. China seems to be one of the chief centres of dispersal of the carp family and also of old-world catfishes.

The regional affinities of Chinese animal life are complex. In the Northeast there are resemblances to the animal life of the Siberian forests. Animals from Central Asia inhabit suitable steppe areas in northern China. The life of the great mountain ranges is Palearctic (relating to a biogeographic region that includes Europe, Asia north of the Himalayas, northern Arabia, and Africa north of the Sahara) but with distinctively Chinese species or genera. To the southeast the lowlands and mountains alike permit direct access to the eastern region. This part of China presents a complete transition from temperate-zone Palearctic life to the wealth of tropical forms distinctive of southeastern Asia. Tropical types of reptiles, amphibians, birds, and mammals predominate in the southernmost Chinese provinces. (K.P.S.)

SETTLEMENT PATTERNS

Rural areas. Except in the mountains and hills, an overwhelming majority of the rural settlements of China consist of sizable compact (nucleated) villages. The formation of such rural settlements is related not only to the increasing population and to a long historical background but also to water supply (the practice of drilling deep wells, for instance) and to defense (especially, in former days, against the attack of bandits). Many of the large villages have no urban atmosphere at all, even with populations of several thousand. Frequent markets may be held between the settlements to enable the peasants to barter their agricultural produce.

On the North China Plain, villages are fairly evenly distributed and are connected with one another by footpaths and cart tracks. Houses are built close together and are mostly made of sun-dried brick or pounded earth. Many of the market towns or even large villages are surrounded by walls. The number and length of the streets depend on the town's size and the nature of the terrain; some streets are merely narrow lanes.

Rural landscapes of central and southern China are dominated by rice fields. The Yangtze River delta has almost every type of human settlement, from the single farmstead to the fairly large market town. Villages to the south and east of Lake T'ai in Kiangsu province are located one to two miles apart. Villages in central China, particularly on the lower Yangtze, are larger than those of North China; many have a few shops that serve not only the villagers but also the dispersed residents nearby. In the centre of dozens of such villages is a market town,

which collects rural produce and distributes manufactured goods. Communication among the villages is mainly by boat, along the dense net of waterways. The most elegant structures in the landscape are the numerous stone bridges that span streams and canals. In the Ch'eng-tu Plain of the Szechwan Basin, a large part of the population lives in isolated farmsteads or scattered hamlets, surrounded by thickets of bamboo and broad-leaved trees.

Cave dwellings

Cave dwellings are another distinctive feature of the Chinese rural landscape. They are common on the Loess Plateau and particularly in northern Shensi, western Shansi, and southeastern Kansu, where the loess is thick and timber is scarce. The cave dwelling has the advantage of being naturally insulated, making it cooler in summer and warmer in winter.

Urban areas. Urbanization and industrialization are often closely related. Urbanization in China accelerated after 1953 as the government intensified its efforts to convert the country into an industrial power.

The dramatic change in the urban landscape is the result of the rapid development of modern manufacturing industries and of communications. Many new towns and cities have been built around manufacturing and mining centres. In the remoter areas of China the first appearance of railways and highways contributed to the rapid growth of some entirely new towns, such as Karmo, Shih-ho-tzu, and Sze-chuan-ho. For larger cities, Wu-lu-mu-ch'i (capital of the Uighur Autonomous Region of Sinkiang), Lanchou (capital of Kansu), and Pao-t'ou (in Inner Mongolia Autonomous Region) provide examples of extremely rapid expansion. Lan-chou lies midway between southeast and northwest China. Pao-t'ou, formerly a bleak frontier town of traders, artisans, and immigrant farmers, has become one of the largest steel centres in China.

The people

ETHNIC AND LINGUISTIC GROUPS

China is a multinational country, with a population composed of a large number of ethnic and linguistic groups. Thus, the basic classification of the population is not so much ethnic as linguistic. The Han (Chinese), the largest group, outnumber the minority groups or minority nationalities in every province or autonomous region except Tibet and Sinkiang. The Han, therefore, form the great homogeneous mass of the Chinese people, sharing the same culture, the same traditions, and the same written language. Some 55 minority groups are spread over approximately three-fifths of the total area of the country. Where these minority groups are found in large numbers, they have been given some semblance of autonomy and self-government; autonomous regions of several types have been established on the basis of the geographic distribution of nationalities.

Han (Chinese)

The government takes great credit for its treatment of these minorities, including care for their economic well-being, the raising of their living standards, the provision of educational facilities, the promotion of their national languages and cultures, and the raising of their levels of literacy, as well as for the introduction of a written language where none existed previously. It must be noted, however, that some minorities, Tibetans in particular, have been subject to varying degrees of repression. Still, of the 50-odd minority languages, only 20 had written forms before the coming of the Communists; and only relatively few written languages—for example, Mongolian, Tibetan, Uighur, Kazak, Thai, and Korean—were in everyday use. Other written languages were used chiefly for religious purposes and by a limited number of persons. Educational institutions for national minorities are a feature of many large cities, notably Peking, Wu-han, Ch'eng-tu, and Lan-chou.

Four major language families are represented in China: the Sino-Tibetan, Altaic, Indo-European, and Austro-asiatic. The Sino-Tibetan family, both numerically and in the extent of its distribution, is the most important; within this family, Han Chinese is the most widely spoken language. Although unified by their tradition, the written characters of their language, and many cultural traits, the Han speak several mutually unintelligible dialects and display marked regional differences. By far the most important Chinese tongue is the Mandarin, or *p'u-t'ung hua*, meaning "ordinary language" or "common language." There are three variants of Mandarin. The first of these is the northern variant, of which the Peking dialect, or Peking *hua*, is typical and which is spoken to the north of the Tsinling Mountains–Huai River line; as the most widespread Chinese tongue, it has officially been adopted as the basis for a national language. The second is the western variant, also known as the Ch'eng-tu or Upper Yangtze variant; this is spoken in the Szechwan Basin and in adjoining parts of southwestern China. The third is the southern variant, also known as the Nanking or Lower Yangtze variant, which is spoken in northern Kiangsu and in southern and central Anhwei. Related to Mandarin are the Hunan, or Hsiang, dialect, spoken by people in central and southern Hunan, and the Kan dialect. The Hui-chou dialect, spoken in southern Anhwei, forms an enclave within the southern Mandarin area.

Less intelligible to Mandarin speakers are the dialects of the southeast coastal region, stretching from Shanghai to Canton. The most important of these is the Wu dialect, spoken in southern Kiangsu and in Chekiang. This is followed, to the south, by the Fu-chou, or Northern Min, dialect of northern and central Fukien and by the Amoy-Swatow, or Southern Min, dialect of southern Fukien and easternmost Kwangtung. The Hakka dialect of southernmost Kiangsi and northeastern Kwangtung has a rather scattered pattern of distribution. Probably the best known of these southern dialects is Yüeh, particularly Cantonese, which is spoken in central and western Kwangtung, Hong Kong, and in southern Kwangsi—a dialect area in which a large proportion of overseas Chinese originated.

In addition to the Han, the Manchu and the Hui (Chinese Muslims) also speak Mandarin and use Chinese characters. The Hui are descendants of Chinese who adopted Islām when it penetrated into China in the 7th century. They are intermingled with the Han throughout much of the country and are distinguished as Hui only in the area of their heaviest concentration, the Hui Autonomous Region of Ningsia. Other Hui communities are organized as autonomous prefectures (*tzu-chih-chou*) in Sinkiang and as autonomous counties (*tzu-chih-hsien*) in Tsinghai, Hopeh, Kweichow, and Yunnan. Increasingly, the Hui have been moving from their scattered settlements into the area of major concentration, possibly, as firm adherents of Islām, in order to facilitate intermarriage with other Muslims.

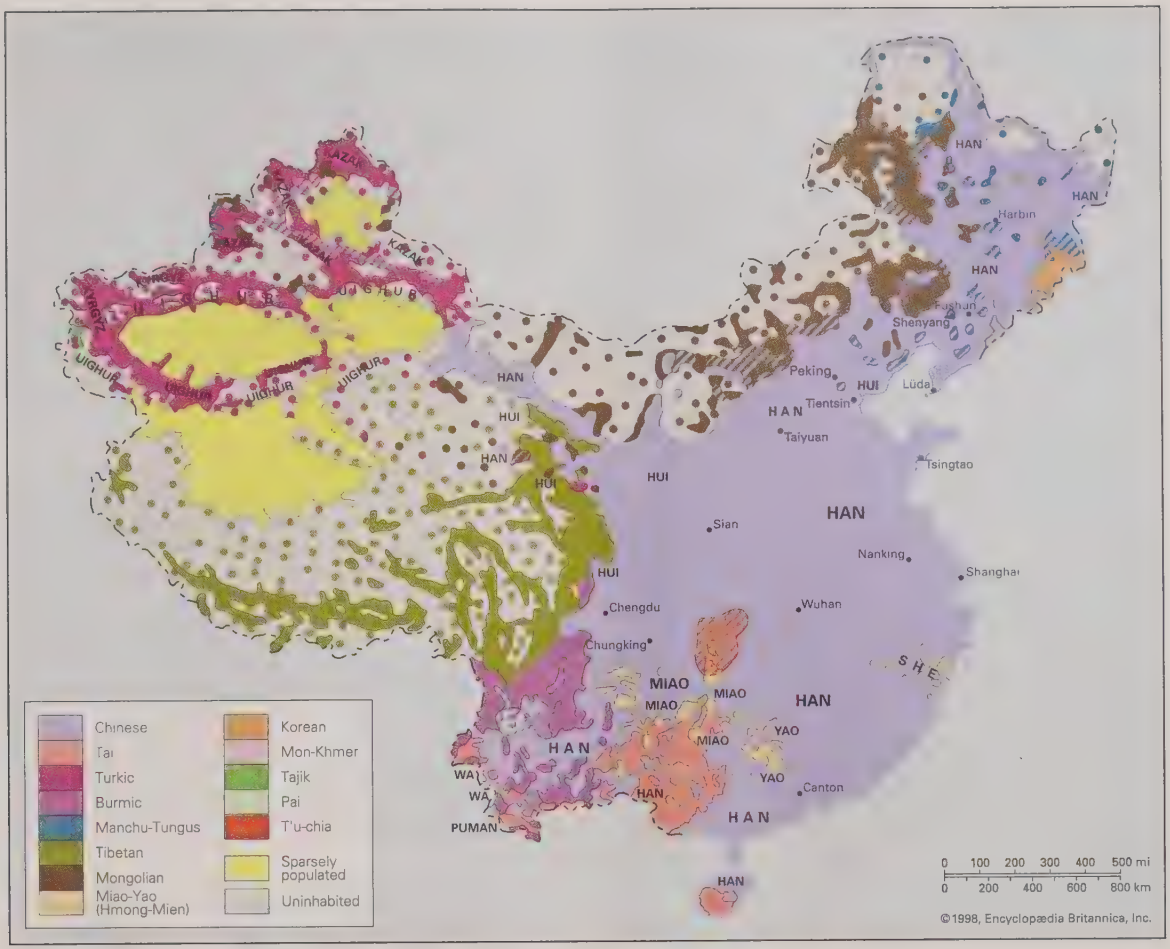
Manchu and Hui

The Manchu declare themselves to be descendants of the Manchu warriors who invaded China in the 17th century and founded the Ch'ing dynasty (1644–1911/12). Ancient Manchu is virtually a dead language, and the Manchu have been completely assimilated into Han Chinese culture. They are found mainly in North China and the Northeast, but they form no separate autonomous areas above the commune level. Some say the Koreans of the Northeast, who form an autonomous prefecture in eastern Kirin, cannot be assigned with certainty to any of the standard language classifications.

The Chuang (Chuang-chia) are China's largest minority group. Most of them live in the Chuang Autonomous Region of Kwangsi. They are also represented in national autonomous areas in neighbouring Yunnan and Kwangtung. They depend mainly on the cultivation of rice for their livelihood. In religion they are animists, worshiping particularly the spirits of their ancestors. The Puyi (Chung-chia) group are concentrated in southern Kweichow, where they share an autonomous prefecture with the Miao (Hmong) group. The T'ung group are settled in small communities in Kwangsi and Kweichow; they share with the Miao group an autonomous prefecture set up in southeast Kweichow in 1956. The Tai speakers are concentrated in southern Yunnan and were established in two autonomous prefectures—one whose population is related most closely to the Tai of northern Thailand and another whose Tai are related to the Shan people of Myanmar (Burma). The Li of Hai-nan Island form a separate group of the Chinese-Tai language branch. They share with the Miao people a district in southern Hai-nan.

Chuang

Tibetans are distributed over the entire Tsinghai-Tibetan



General ethnic composition of China.

plateau. Outside Tibet, Tibetan minorities constitute autonomous prefectures and autonomous counties. There are five Tibetan autonomous prefectures in Tsinghai, two in Szechwan, and one each in Yunnan and Kansu. The Tibetans still keep their tribal characteristics, but few of them are nomadic. Though essentially farmers, they also raise livestock and, as with other tribal peoples in the Chinese far west, also hunt to supplement their food supply. The major religion of Tibet has been Tibetan Buddhism since about the 17th century; before 1959 the social and political institutions of this region were still based largely on this faith. Many of the Yi (Lolo) were concentrated in two autonomous prefectures—one in southern Szechwan and another in northern Yunnan. They raise crops and sometimes keep flocks and herds.

The Miao-Yao (Hmong-Mien) branch, with their major concentration in Kweichow, are distributed throughout the central south and southwestern provinces and are found also in some small areas in eastern China. They are subdivided into many rather distinct groupings. Most of them have now lost their traditional tribal traits through the influence of the Han, and it is only their language that serves to distinguish them as tribal peoples. Two-thirds of the Miao are settled in Kweichow, where they share two autonomous prefectures with the T'ung and Puyi groups. The Yao people are concentrated in the Kwangsi-Kwangtung-Hunan border area.

In some areas of China, especially in the southwest, there are many different ethnic groups that are geographically intermixed. Because of language barriers and different economic structures, these peoples all maintain their own cultural traits and live in relative isolation from one another. In some places the Han are active in the towns and in the fertile river valleys, while the minority peoples depend for their livelihood on more primitive forms of agriculture or on grazing their livestock on hillsides and mountains. The vertical distribution of these peoples is in zones—usually the higher they live, the less complex their way of life. In former times they did not mix well with one another, but now, with highways penetrating deep into their settlements, they have better opportunities to communicate with other groups and are also enjoying better living conditions.

The Altaic language family

While the minorities of the Sino-Tibetan language family are thus concentrated in the south and southwest, the second major language family—the Altaic—is represented entirely by minorities in northwestern and northern China. The Altaic family falls into three branches: Turkic, Mongolian, and Manchu-Tungus. The Turkic language branch is by far the most numerous of the three Altaic branches. The Uighur, who are Muslims, form the largest Turkic minority. They are distributed over chains of oases in the Tarim Basin and in the Dzungarian Basin of Sinkiang. They mainly depend on irrigation agriculture for a livelihood. Other Turkic minorities in Sinkiang are splinter groups of nationalities living in neighbouring nations of Central Asia, including the Kazaks and Kyrgyz. All these groups are adherents of Islām. The Kazaks and Kyrgyz are pastoral nomadic peoples, still showing traces of tribal organization. The Kazaks live mainly in northwestern and northeastern Sinkiang as herders, retiring to their camps in the valleys when winter comes; they are established in the I-li-ha-sa-k'o (Ili Kazak) Autonomous Prefecture. The Kyrgyz are high-mountain pastoralists and are concentrated mainly in the westernmost part of Sinkiang.

The Mongolians, who are by nature a nomadic people, are the most widely dispersed of the minority nationalities of China. Most of them are inhabitants of the Inner Mongolia Autonomous Region. Small Mongolian and Mongolian-related groups of people are scattered throughout the vast area from Sinkiang through Tsinghai and Kansu and into the provinces of the Northeast (Kirin, Heilungkiang, and Liaoning). In addition to the Inner Mongolia Autonomous Region, the Mongolians are established in two autonomous prefectures in Sinkiang, a joint autonomous prefecture with Tibetans and Kazaks in Tsinghai, and

several autonomous counties in the western area of the Northeast. Some of them retain their tribal divisions and are pastoralists, but large numbers of Mongolians engage in sedentary agriculture, and some of them combine the growing of crops with herding. The tribes, who are dependent upon animal husbandry, travel each year around the pastureland—grazing sheep, goats, horses, cattle, and camels—and then return to their point of departure. A few take up hunting and fur trapping in order to supplement their income. The Mongolian language consists of several dialects, but in religion it is a unifying force; most Mongolians are believers in Tibetan Buddhism.

A few linguistic minorities in China belong to neither the Sino-Tibetan nor the Altaic language family. The Tajik of westernmost Sinkiang are related to the population of Tajikistan and belong to the Iranian branch of the Indo-European family. The Kawa people of the China–Burma border area belong to the Mon-Khmer branch of the Austro-Asiatic family.

POPULATION GROWTH

Historical records show that, as long ago as 800 BC, in the early years of the Chou dynasty, China was already inhabited by about 13,700,000 people. Until the last years of the Hsi (Western) Han dynasty, about AD 2, comparatively accurate and complete registers of population were kept, and the total population in that year was given as 59,600,000. This first Chinese census was intended mainly as a preparatory step toward the levy of a poll tax. Many members of the population, aware that a census might work to their disadvantage, managed to avoid reporting; this explains why all subsequent population figures were unreliable until 1712. In that year the Emperor declared that an increased population would not be subject to tax; population figures thereafter gradually became more accurate.

The census of AD 2

During the later years of the Pei (Northern) Sung dynasty, in the early 12th century, when China was already in the heyday of its economic and cultural development, the total population began to exceed 100,000,000. Later, uninterrupted and large-scale invasions from the north reduced the country's population. When national unification returned with the advent of the Ming dynasty, the census was at first strictly conducted. The population of China, according to a registration compiled in 1381, was quite close to the one registered in AD 2.

From the 15th century onward, the population increased steadily; this increase was interrupted by wars and natural disasters in the mid-17th century and slowed by the internal strife and foreign invasions in the century that preceded the Communist takeover in 1949. During the 18th century China enjoyed a lengthy period of peace and prosperity, characterized by continual territorial expansion and an accelerating population increase. In 1762 China had a population of more than 200,000,000, and by 1834 the population had doubled. It should be noted that during this period there was no concomitant increase in the amount of cultivable land; from this time on, land hunger became a growing problem.

After 1949 sanitation and medical care greatly improved, epidemics were brought under control, and the younger generation became much healthier. Public hygiene also improved, resulting in a death rate that declined faster than the birth rate and a rate of population growth that speeded up again. Population reached 1,000,000,000 in the early 1980s.

The continually growing population poses major problems for the government. Faced with difficulties in obtaining an adequate food supply and in combating the generally low standard of living, the authorities sponsored a drive for birth control in 1955–58. A second attempt at population control began in 1962, when advocacy of late marriages and the use of contraceptives became prominent parts of the program. The outbreak of the Cultural Revolution interrupted this second family-planning drive, but in 1970 a third and much stricter program was initiated. This program attempted to make late marriage and family limitation obligatory, and it culminated in 1979 in efforts to implement a policy of one child per family.

Drive for birth control

Other developments affected the rate of population growth more than the first two official family-planning campaigns. For example, although family planning had been rejected by Chinese Communist Party Chairman Mao Zedong (Mao Tse-tung) in 1958, the Great Leap Forward that he initiated in that year (see below *The economy*) caused a massive famine that resulted in more deaths than births and a reduction of population in 1960. By 1963 recovery from the famine produced the highest rate of population increase since 1949, at more than 3 percent, although the second birth-control campaign had already begun.

Since the initiation of the third family-planning program in 1970, however, state efforts have been much more effective. China's population growth rate is now unusually low for a developing country, although the huge size of its population still results in a large annual net population growth.

POPULATION DISTRIBUTION

Because of complex natural conditions, the population of China is quite unevenly distributed. Population density varies strikingly, with the greatest contrast occurring between the eastern half of China and the lands of the west and the northwest. Exceptionally high population densities occur in the Yangtze Delta, in the Pearl River Delta, and on the Ch'eng-tu Plain of the western Szechwan Basin. Most of the high-density areas are coterminous with the alluvial plains on which intensive agriculture is centred.

In contrast, the isolated, extensive western and frontier regions, which are much larger than any European nation, are sparsely populated. Extensive uninhabited areas include the extremely high northern part of Tibet, the sandy wastes of the central Tarim and eastern Dzungarian basins in Sinkiang, and the barren desert and mountains east of Lop Nor.

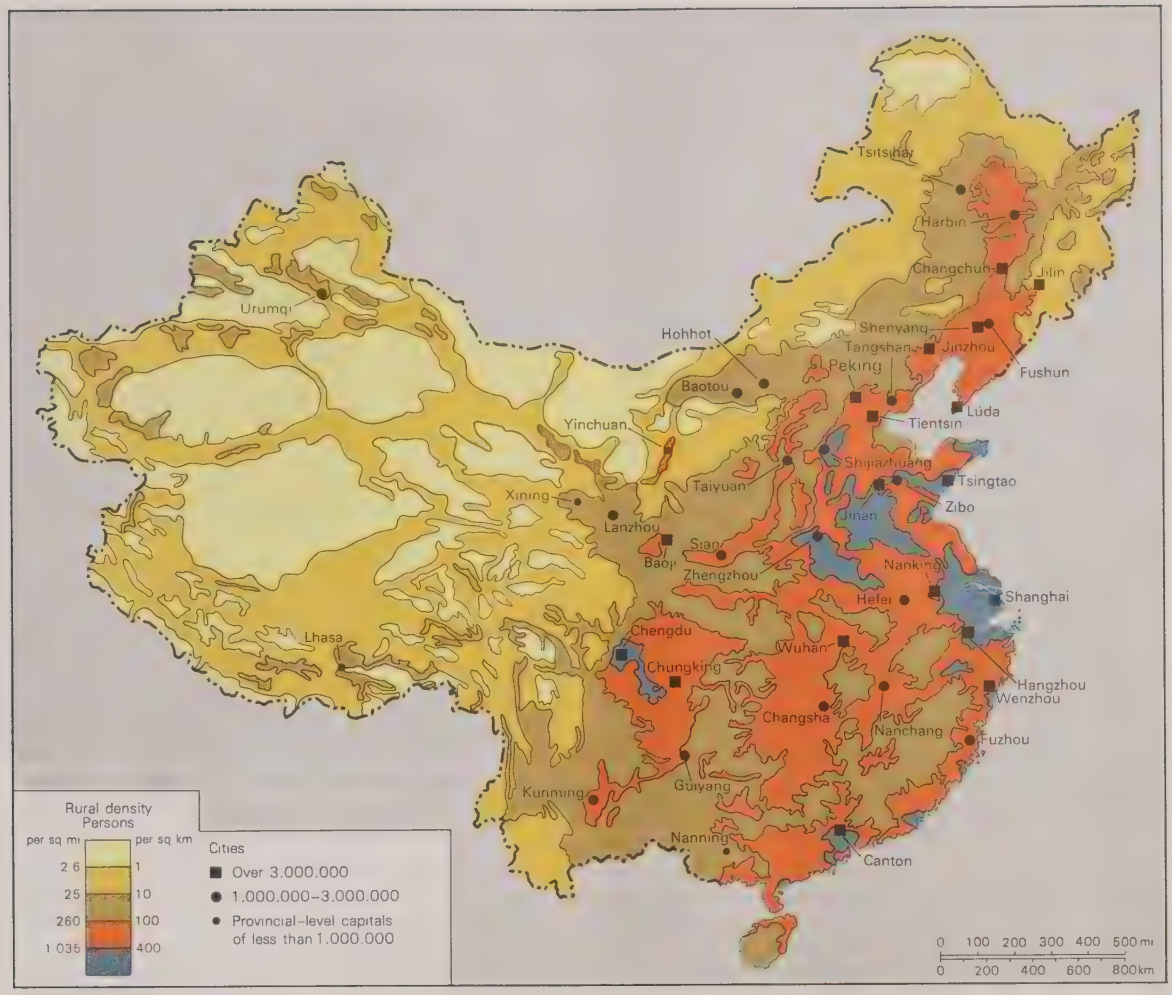
In the 1950s the government became increasingly aware of the importance of the frontier regions and initiated a drive for former members of the military and young intellectuals to settle there. Consequently, the population has increased, following the construction of new railways and highways that traverse the wasteland; a number of small mining and industrial towns have also sprung up.

INTERNAL MIGRATION

Migrations have occurred often throughout the history of China. Sometimes they took place because a famine or political disturbance would cause the depopulation of an area already intensively cultivated, after which people in adjacent crowded regions would move in to occupy the deserted land. Sometime between 1640 and 1646 a peasant rebellion broke out in Szechwan, and there was a great loss of life. People from Hupeh and Shensi then entered Szechwan to fill the vacuum, and the movement continued until the 19th century. Again, during the middle of the 19th century, the Taiping Rebellion caused another large-scale disruption of population. Many people in the Lower Yangtze were massacred by the opposing armies, and the survivors suffered from starvation. After the defeat of the rebellion, people from Hupeh, Hunan, and Honan moved into the depopulated areas of Kiangsu, Anhwei, and Chekiang, where farmland was lying uncultivated for want of labour. Similar examples are provided by the Nien Rebellion in the Huai River region in the 1850s and '60s, the Muslim rebellions in Shensi and Kansu in the 1860s and '70s, and the great Shensi and Shansi famine of 1877–78.

In modern history the domestic movement of the Han to Manchuria (now known as the Northeast) is the most significant. Even before the establishment of the Ch'ing dynasty in 1644, Manchu soldiers launched raids into North China and captured Han labourers, who were then obliged to settle in Manchuria. In 1668 the area was closed to further Han migration by an Imperial decree, but this ban was never effectively enforced. By 1850, Han settlers had secured a position of dominance in their colonization of Manchuria. The ban was later partially lifted, partly because the Manchu rulers were harassed by disturbances among the teeming population of China proper and partly

Migration to Manchuria



Population density of China.
By courtesy of the Central Intelligence Agency

because the Russian Empire time and again tried to invade sparsely populated and thus weakly defended Manchuria. The ban was finally removed altogether in 1878, but settlement was encouraged only after 1900.

The influx of people into Manchuria was especially pronounced after 1923, and incoming farmers rapidly brought a vast area of virgin prairie under cultivation. About two-thirds of the immigrants entered Manchuria by sea, and one-third came overland. Because of the severity of the winter weather, migration in the early stage was highly seasonal, usually starting in February and continuing through the spring. After the autumn harvest a large proportion of the farmers returned south. As Manchuria developed into the principal industrial region of China, however, large urban centres arose, and the nature of the migration changed. No longer was the movement primarily one of agricultural resettlement; instead it became essentially a rural-to-urban movement of interregional magnitude.

Post-1949 migration

After 1949 the government's efforts to foster planned migration into interior and border regions produced noticeable results. Although the total number of people involved in such migrations is not known, it has been estimated that by 1980 about 25 to 35 percent of the population of such regions and provinces as Inner Mongolia, Sinkiang, Heilungkiang, and Tsinghai consisted of recent migrants, and migration had raised the percentage of Han in Sinkiang from about 10 to 40 percent of the total. Efforts to control the growth of large cities led to the resettlement of 20,000,000 urbanites in the countryside after the failure of the Great Leap Forward and of 17,000,000 urban-educated youths in the decade after 1968. Within the next decade, however, the majority of these "rusticated youths" were allowed to return to the cities, and new migration from rural areas pushed urban population totals upward once again. (C.-S.Ch./K.G.L.)

The economy

Despite China's size, the wealth of its resources, and the fact that about one-fifth of the world's population lives within its borders, its role in the world economy traditionally has been relatively small. Since the late 1970s, however, when China decided to increase its interaction with the international economy, its role in world trade has steadily grown and its importance to the international economy has also increased apace. China's foreign trade has since grown faster than its gross national product (GNP). The government's decision to permit China to be used by Western firms as an export platform is making the country a competitive threat to its neighbours South Korea, Singapore, Malaysia, Thailand, and Indonesia.

The Chinese economy thus has been in a state of transition since the late 1970s as the country has moved away from a Soviet-type economic system. Agriculture has been decollectivized, the nonagricultural private sector has grown rapidly, and government priorities have shifted toward light and hi-tech, rather than heavy, industries. Nevertheless, key bottlenecks continue to constrain growth. Available energy is insufficient to run installed industrial capacity; the transport system is inadequate to move sufficient quantities of such critical items as coal; and the communications system cannot meet the needs of a centrally planned economy of China's size and complexity.

China's underdeveloped transport system—combined with important differences in the availability of natural and human resources and in industrial infrastructure—has produced significant variations in the regional economies of China. The three wealthiest regions are along the southeast coast, centred on the Pearl River Delta; along the east coast, centred on the Lower Yangtze River; and near the Po Hai (Gulf of Chihli), in the Peking–Tientsin–Liaoning

region. It is the rapid development of these areas that is expected to have the most significant effect on the Asian regional economy as a whole, and Chinese government policy is designed to remove the obstacles to accelerated growth in these wealthier regions. At the same time, a major priority of the government is the economic development of the interior of the country to help it catch up with the more prosperous coastal areas.

China is the world's largest producer of rice and is among the principal sources of wheat, corn (maize), tobacco, soybeans, peanuts (groundnuts), and cotton. The country is one of the world's largest producers of a number of industrial and mineral products—including cotton cloth, tungsten, and antimony—and is an important producer of cotton yarn, coal, crude oil, and a number of other products. Its mineral resources are probably among the richest in the world but are only partially developed. China has acquired some highly sophisticated production facilities through foreign investment and joint ventures with foreign partners. The technological level and quality standards of many of its industries are rapidly improving.

Technological level

Other major problems concern the labour force and the pricing system. Underemployment is common in both urban and rural areas, and the fear of the disruptive effects of widespread unemployment is strong. The prices of some key commodities, especially of industrial raw materials and major industrial products, are still determined by the state. In most cases, basic price ratios were set in the 1950s and are often irrational in terms of current production capabilities and demands. China's increasing contact with the international economy and its growing use of market forces to govern the domestic allocation of goods have exacerbated this problem. Over the years, large subsidies were built into the price structure, and these subsidies grew substantially after the late 1970s.

RESOURCES

Mineral resources. China is well endowed with mineral resources, the most important of which is coal. Although deposits are widely scattered (some coal is found in every province), most of the total is located in the northern part of the country. The province of Shansi, in fact, is thought to contain about half of the total; other important coal-bearing provinces include Heilungkiang, Liaoning, Kirin, Hopeh, and Shantung. Apart from these northern provinces, significant quantities of coal are present in Szechwan, and there are some deposits of importance in Kwangtung, Kwangsi, Yunnan, and Kweichow. A large part of the country's reserves consists of good bituminous coal, but there are also large deposits of lignite. Anthracite is present in several places (especially Liaoning, Kweichow, and Honan), but overall it is not very significant.

In order to ensure a more even distribution of coal supplies and to reduce the strain on the less than adequate transport network, the authorities have pressed for the development of a large number of small, locally run mines throughout the country. This campaign was energetically pursued after the 1960s, with the result that thousands of small pits have been established, and they produce more than half the country's coal. This output, however, is typically expensive and is used for local consumption.

Oil and natural gas

China's onshore oil resources are located in the Northeast and in Sinkiang, Kansu, Tsinghai, Szechwan, Shantung, and Honan provinces. Shale oil is found in a number of places, especially at Fu-shun in Liaoning, where the deposits overlie the coal reserves, and in Kwangtung. Light oil of high quality has been found in the Pearl River estuary of the South China Sea, the Tsaidam Basin in Tsinghai, and the Tarim Basin in Sinkiang. China contracted with Western oil companies to jointly explore and develop oil deposits in the China Sea, the Yellow Sea, the Gulf of Tonkin, and the Po Hai. The country consumes most of its oil output but exports some crude oil and oil products.

The extent of China's natural gas reserves is unknown, as relatively little exploration for natural gas has been done. Szechwan Province accounts for almost half of the known natural gas reserves and production. Most of the rest of China's natural gas is associated gas produced in the Northeast's major oil fields, especially Ta-ch'ing. Other gas deposits have been found in the Tsaidam Basin, Hopeh, Kiangsu, Shanghai, and Chekiang, and offshore to the southwest of Hai-nan Island.

Iron ore is found in most provinces, and there are reserves on Hai-nan Island. Kansu, Kweichow, southern Szechwan, and Kwangtung provinces have rich deposits. The largest mined reserves are located north of the Yangtze River and supply neighbouring iron and steel enterprises. With the exception of nickel, chromium, and cobalt, China is well supplied with ferroalloys and manganese. Reserves of tungsten are also known to be fairly large. Copper resources are moderate, and high-quality ore is present only in a few deposits. Discoveries have been reported from the Hui Autonomous Region of Ningsia. Lead and zinc are available, and bauxite resources are thought to be plentiful. China's antimony reserves are the largest in the world. Tin resources are plentiful, and there are fairly rich deposits of gold. There are important deposits of phosphate rock in a number of areas. Pyrites occur in several places; Liaoning, Hopeh, Shantung, and Shansi have the most important deposits. China also has large resources of fluorite (fluorspar), gypsum, asbestos, and cement.

China also produces a fairly wide range of nonmetallic minerals. One of the most important of these is salt, which is derived from coastal evaporation sites in Kiangsu, Hopeh, Shantung, and Liaoning, as well as from extensive salt fields in Szechwan, Ningsia, and the Tsaidam Basin.

Hydroelectric resources. In view of China's extensive river network and mountainous terrain, there is ample potential for the production of hydroelectric power. Most of the total hydroelectric capacity is in the southwest, where coal supplies are poor but demand for energy is rapidly growing. The potential in the Northeast is fairly small, but it was there that the first hydroelectric stations were built (by the Japanese). As a result of considerable seasonal fluctuations in rainfall, the flow of rivers tends to drop during the winter, forcing many power stations to operate at less than normal capacity, while in the summer, on the other hand, floods often interfere with production.

Hydroelectric stations

Thus, while China has rich overall energy potential, most remains to be developed. In addition, the geographical distribution of energy places most of these resources far from their major industrial users. Basically the Northeast is rich in coal and oil, the central part of North China has abundant coal, and the southwest has great hydroelectric potential. But the industrialized regions around Canton and the Lower Yangtze region around Shanghai have too little energy, while there is little industry located near major energy resource areas other than in the southern part of the Northeast.

AGRICULTURE

Farming and forestry. As a result of topographic and climatic features, the area suitable for cultivation is small: only about 10 percent of China's total land area. Of this, slightly more than half is unirrigated, and the remainder is divided roughly equally between paddy fields and other irrigated areas. Nevertheless, about 70 percent of the population lives in the countryside, and until the 1980s a high percentage of them made their living directly from farming. Since then, many have been encouraged to leave the fields and pursue other activities, such as handicrafts, commerce, and transport; and by the mid-1980s farming accounted for less than half of the value of rural output.

The quality of the soil varies. Environmental problems such as floods, drought, and erosion pose serious threats in many parts of the country. The wholesale destruction of forests gave way to an energetic reforestation program that proved inadequate, and forest resources are still fairly meagre. The principal forests are found in the Tsinling Mountains and the central mountains and on the Szechwan–Yunnan plateau. Because they are inaccessible, the Tsinling forests are not worked extensively, and much of the country's timber comes from Heilungkiang, Kirin, Szechwan, and Yunnan.

Western China, comprising Tibet, Sinkiang, and Tsinghai, has little agricultural significance except for areas of oasis farming and cattle raising. Rice, China's most im-

Harvesting rice in a paddy field in the Ch'eng-tu Plain, Szechwan Province.
Peter Carmichael—Aspect Picture Library, London

portant crop, is dominant in the southern provinces, many of which yield two harvests a year. In the North wheat is of the greatest importance, while in central China wheat and rice vie with each other for the top place. Millet and kaoliang (a variety of grain sorghum) are grown mainly in the Northeast and some central provinces, which—together with some northern areas—also provide considerable quantities of barley. Most of the soybean crop is derived from the North and the Northeast; corn (maize) is grown in the centre and the North, while tea comes mainly from the hilly areas of the southeast. Cotton is grown extensively in the central provinces, but it is also found to a lesser extent in the southeast and in the North. Tobacco comes from the centre and parts of the South. Other important crops are potatoes, sugar beets, and oilseeds.

Farm machinery

Although the use of farm machinery has been increasing, for the most part the Chinese peasant depends on simple, nonmechanized farming implements. Good progress has been made in improving water conservancy, and about half the cultivated land is under irrigation.

Livestock and fishing. Animal husbandry constitutes the second most important component of agricultural production. China is the world's leading producer of pigs, chickens, and eggs, and it also has sizable herds of sheep and cattle. Since the mid-1970s, greater emphasis has been placed on increasing the livestock output.

China has a long tradition of ocean and freshwater fishing and of aquaculture. Pond raising has always been important and has been increasingly emphasized to supplement coastal and inland fisheries threatened by overfishing and to provide such valuable export commodities as prawns.

INDUSTRY

The development of industry has been given considerable attention since the advent of the Communist regime. Overall industrial output often has grown at a rate of more than 10 percent per year, and China's industrial workforce probably exceeds the combined total for all other developing countries. Industry has surpassed all other sectors in economic growth and degree of modernization.

Among the various industrial branches the metallurgical and machine-building industries have received a high priority. These two branches alone now account for about two-fifths of the total gross value of industrial output. In these, as in most other state-owned industry, however, innovation has generally suffered at the hands of a system that has rewarded increases in gross output rather than improvements in variety and quality. China, therefore, still imports significant quantities of specialized steels. Much of the country's steel output comes from a small number of producing centres, the largest being An-shan in Liaoning.

The principal preoccupation of authorities in the chemical industry is to expand the output of chemical fertilizers, plastics, and synthetic fibres. The growth of this industry has placed China among the world's leading producers of nitrogenous fertilizers. In the consumer goods sector the main emphasis is on textiles, clothing, shoes, processed foods, and toys, which also form an important part of China's exports. Textiles, a rapidly growing proportion of which consists of synthetics, continue to be important, but less so than before. The industry tends to be scattered throughout the country, but there are a number of important textile centres, including Shanghai, Canton, and Harbin.

Energy production has increased rapidly, but it still falls considerably short of demand. This is partly because energy prices for a long time were held so low that industries had few incentives to conserve. Coal provides more than half of China's energy consumption. Petroleum production, which began growing rapidly from an extremely low base in the early 1960s, has basically remained at the same level since the late 1970s. There are large petroleum reserves in the inaccessible northwest and potentially significant offshore petroleum deposits, but about half of the country's oil production still comes from the major Ta-ch'ing oil field in the Northeast. China has much, and mostly untapped, hydroelectric power potential and natural gas reserves of unknown extent. The massive Three Gorges Dam project on the Yangtze River east of Chungking, under construction since 1994, will vastly increase hydroelectric production. Nuclear power plants are located near Shanghai and Canton.

Energy resources

Overall, the distribution of industry remains very uneven, despite serious efforts from the mid-1950s to the late 1970s to build up industry in the interior at the cost of the major cities on the east coast. While percentage growth of industry in the interior provinces generally greatly exceeded that of the coastal areas, the far larger initial industrial base of the latter meant that a few coastal regions continued to dominate China's industrial econo-

Greenhill—Black Star

my. Thus, Shanghai alone produces about 10 percent of China's gross value of industrial output, and the east coast accounts for about 60 percent of the national industrial output.

FINANCE

China's financial institutions are owned by the state. The principal instruments of fiscal and financial control are the People's Bank of China and the Ministry of Finance, both subject to the authority of the State Council. The People's Bank, which replaced the Central Bank of China in 1950 and gradually took over private banks, fulfills many of the functions of Western central and commercial banks. It issues the currency, controls circulation, and plays an important role in disbursing budgetary expenditures. Furthermore, it handles the accounts, payments, and receipts of government organizations and other bodies, which enables it to exercise detailed supervision over their financial and general performance in the light of the state's economic plans.

The People's Bank is also responsible for foreign trade and other overseas transactions (including remittances by overseas Chinese), but these functions are exercised through the Bank of China, which maintains branch offices in a number of European and Asian countries.

Other important financial institutions include the People's Construction Bank of China, responsible for capitalizing a portion of overall investment and for providing capital funds for certain industrial and construction enterprises; the Industrial and Commercial Bank of China, which conducts ordinary commercial transactions and acts as a savings bank for the public; the Agricultural Bank of China, which serves the agricultural sector; and the China Investment Bank, which handles foreign investment. Many foreign banks maintain offices in China's larger cities and the special economic zones.

China's economic reforms greatly increased the economic role of the banking system. Whereas virtually all investment capital was previously provided on a grant basis in the state plan, policy has shifted to a loan basis through the various state financial institutions. More generally, increasing amounts of funds are made available through the banks for economic purposes. Enterprises and individuals can go to the banks to obtain loans outside the state plan, and this has proved to be a major source of financing both for new firms and for the expansion and modernization of older enterprises.

Foreign capital

Foreign sources of capital also have become increasingly important. China has received loans from the World Bank and several United Nations programs, as well as from countries (particularly Japan) and commercial banks. Hong Kong and Taiwan have become major conduits for, as well as sources of, this investment.

TRADE

Trade has become an increasingly important part of China's overall economy. The direction of China's foreign trade has undergone marked changes since the early 1950s. In 1950 more than 70 percent of the total was accounted for by trade with non-Communist countries, but by 1954—the year after the end of the Korean War—the situation was completely reversed, and Communist countries accounted for about 74 percent. During the next few years, the Communist world lost some of its former importance, but it was only after the Sino-Soviet breach of 1960, which resulted in the cancellation of Soviet credits and the withdrawal of Soviet technicians, that the non-Communist world began to see a rapid improvement in its position. In 1965 China's trade with other socialist countries made up only some 30 percent of the total.

A significant part of China's trade with the developing countries has been financed through credits, grants, and other forms of assistance. At first, from 1953 to 1955, aid went mainly to North Korea and North Vietnam and some other Communist states; but from the mid-1950s large amounts—mainly grants and long-term, interest-free loans—were promised to politically uncommitted developing countries. The principal efforts were made in Asia—especially to Indonesia, Burma (now Myanmar), Pakistan, and Ceylon (now Sri Lanka)—but large loans were also granted in Africa (Ghana, Algeria, Tanzania) and in the Middle East (Egypt). After Mao Zedong's (Mao Tse-tung's) death in 1976, however, the Chinese scaled back their efforts.

During the 1980s and '90s, China's foreign trade came full cycle. Trade with all Communist countries diminished to insignificance, especially with the demise of most socialist states. By contrast, trade with non-Communist developed and developing countries became predominant. In general, China has run a significant trade surplus with developing countries and a trade deficit with developed countries. Hong Kong became one of China's major trading partners prior to its reincorporation into the country; it remains prominent in domestic trade, notably in its reliance on the mainland for agricultural products. Taiwan also has become an important trading partner.

China's imports

Most of China's imports consist of industrial supplies and capital goods, notably machinery and motor vehicles. The majority of each category of these goods comes from the developed countries, primarily Japan and the United States and, to a lesser extent, the European Union. Regionally, almost half of China's imports come from East and Southeast Asia, and about one-fourth of China's exports go to the same destinations.

About 70 percent of China's exports consist of manufactured goods, of which machinery and transport equipment, textiles, and rubber and metal products are by far the most important. Agricultural products, coal, and oil are also significant exports.

ADMINISTRATION OF THE ECONOMY

The role of the government. China is a socialist country, and the government plays a predominant role in the economy. In the industrial sector, for example, the state owns outright firms that produce a large proportion of the gross value of industrial output, and most of the remainder is owned collectively. In the urban sector the government has set the prices for key commodities, determined the level and general distribution of investment funds, prescribed output targets for major enterprises and branches, allocated energy resources, set wage levels and employment targets, run the wholesale and retail networks, and controlled financial policy and the banking system. The foreign trade system became a government monopoly in the early 1950s. In the countryside, from the mid-1950s, the government prescribed cropping patterns, set the level of prices, and fixed output targets for all major crops.

By the early 21st century much of the above system was in the process of changing, as the role of the central government in managing the economy was reduced and the role of both private initiative and market forces increased. Nevertheless, the government continued to play a dominant role in the urban economy, and its policies on such issues as agricultural procurement still exerted a major influence on performance in the rural sector.

The effective exercise of control over the economy requires an army of bureaucrats and a highly complicated chain of command, stretching from the top down to the level of individual enterprise. The Communist Party reserves the right to make broad decisions on economic priorities and policies, but the government apparatus headed by the State Council assumes the major burden of running the economy. The State Planning Commission and the Ministry of Finance also are concerned with the functioning of virtually the entire economy.

The entire planning process involves a great deal of consultation and negotiation. The great advantage of including a project in an annual plan is that the raw materials, labour, financial resources, and markets are guaranteed by directives that have the force of law. In fact, however, a great deal of economic activity goes on outside of the scope of the detailed plan, and the tendency has been for the plan to become narrower rather than broader in scope.

Types of economic activity

There are three types of economic activity in China—those stipulated by mandatory planning, those done according to indicative planning (in which central planning of economic outcomes is indirectly implemented), and those governed by market forces. The second and third

categories have grown at the expense of the first, but goods of national importance and almost all large-scale construction come under the mandatory planning system. The market economy generally involves small-scale or highly perishable items that circulate within local market areas only. Almost every year brings additional changes in the lists of goods that fall under each of the three categories.

Operational supervision over economic projects has devolved primarily to provincial, municipal, and county governments. In addition, enterprises themselves are gaining increased independence in a range of activity. Overall, therefore, the Chinese industrial system contains a complex mixture of relationships. In general, the State Council exercises relatively tight control over resources deemed to be of core importance for the performance of the entire economy. Less key aspects of the system are devolved to lower levels for detailed decisions and management. In all spheres, moreover, the need to coordinate units that are in different bureaucratic hierarchies produces a great deal of informal bargaining and the building of consensus.

Although the state controlled agriculture in the 1950s and '60s, rapid changes were made in the system from the late 1970s. The major vehicles for dictating state priorities—the people's communes and their subordinate teams and brigades—have been either abolished or vastly weakened. Peasant incentives have been raised both by price increases for state-purchased agricultural products and by permission to sell excess production on a free market. Greater freedom is permitted in the choice of what crops to grow, and peasants are allowed to contract for land that they will work, rather than simply working most of the land collectively. The system of procurement quotas (fixed in the form of contracts) is being phased out, although the state can still buy farm products and control surpluses in order to affect market conditions.

From the 1950s to the '80s the central government's revenues derived chiefly from the profits of the state enterprises, which were remitted to the state. Some government revenues also came from taxes, of which the most important was the general industrial and commercial tax. The trend, however, has been for remitted profits of the state enterprises to be replaced with taxes on those profits. Initially, this tax system was adjusted so as to allow for differences in the capitalization and pricing situations of various firms, but eventually more uniform tax schedules were to be enforced.

Trade unions. Chinese trade unions are organized on a broad industrial basis. Membership is open to those who rely on wages for the whole or a large part of their income—a qualification that excludes most agricultural workers. In theory, membership is not compulsory, but in view of the unions' role in the distribution of social benefits, the economic pressure to join is considerable. The lowest unit is the enterprise union committee. Individual trade unions also operate at the provincial level, and there are trade union councils that coordinate all union activities within a particular area and operate at county, municipal, and provincial levels. At the top of the movement is the All-China Federation of Trade Unions, which discharges its functions through a number of regional federations.

Authority of the unions

In theory, the appropriate trade union organizations are consulted on the level of wages as well as on wage differentials, but in practice their role in these and similar matters is insignificant. They do not engage in collective bargaining—not at all surprising, since their principal duties include assisting the party and promoting production. In fulfilling these tasks, they have a role in enforcing labour discipline. From the point of view of the membership, the most important activities concern the social and welfare services. Thus, it is the unions that look after industrial safety; organize social and cultural activities; provide services such as clinics, rest and holiday homes, hostels, libraries, and clubs; and administer old-age pensions, workers' insurance, disability benefits, and other welfare schemes.

Economic policies. In the 1950s and '60s a number of far-reaching changes occurred in China's economic policies and priorities. During the First Five-Year Plan period (1953–57), emphasis was placed on rapid industrial development, partly at the expense of other sectors of the economy. The bulk of the state's investment was channeled into the industrial sector, while agriculture, which occupied more than 80 percent of the economically active population, was forced to rely on its own meagre capital resources for a substantial part of its fund requirements. Within industry, iron and steel, electric power, coal, heavy engineering, building materials, and basic chemicals were given first priority; in accordance with Soviet practice, the aim was to construct large, sophisticated, and highly capital-intensive plants.

This program could not be financed out of domestic resources, and a large number of the new plants were built with Soviet technical and financial assistance. The policy led to a rapid growth in heavy industry, but a few months after the introduction of the Second Five-Year Plan in 1958—which was to be on the same lines as its predecessor—the policy of the Great Leap Forward was announced. In agriculture, this involved the formation of communes, the abolition of private plots, and the increasing of output through greater cooperation and greater physical effort. In industry, the construction of large plants was to continue; but it was to be supplemented by a huge small-industry drive, making use of a large number of small, simple, locally built and run plants. The Chinese peasant, however, was not ready for the communes, and a spectacular drop in agricultural production ensued. Meanwhile, the indiscriminate backyard production drive failed to achieve the desired effects and yielded large quantities of expensively produced, substandard goods. These difficulties were aggravated by the withdrawal of Soviet aid and technicians, who made a point of taking their blueprints with them. In consequence, by late 1960 the country faced an economic crisis of the first order.

Great Leap Forward

The response of the authorities was a complete about-face in policy. Private plots were restored, the size of the communes was reduced, and greater independence was given to the production team. There was also a mass transfer of the unemployed from industry to the countryside, and industrial investment was temporarily slashed in order to free resources for farm production. This policy, which led to an immediate improvement in the agricultural situation, was maintained until 1963, when it again became possible to redirect some resources to the capital goods industry. As a result, industrial production and construction gathered some momentum, but care was taken to avoid the earlier mistake of sacrificing food production to iron and steel and similar industries. Then, in 1966 the "Great Proletarian Cultural Revolution" began. Unlike the Great Leap, the Cultural Revolution did not have an explicit economic philosophy. Nevertheless, industrial production was badly affected by the ensuing confusion and strife.

The Cultural Revolution left some difficult legacies for the Chinese economy. In industry, wages had been frozen and bonuses canceled. Combined with the policies of employing more workers than necessary to soak up unemployment and of never firing workers once hired, this action essentially eliminated incentives to work hard. In addition, technicians and many managers lost their authority and could not play an effective role in production in the wake of the movement. The entire urban system, moreover, provided less than minimal incentives to achieve efficiency in production. While overall output continued to grow, capital–output ratios declined. In agriculture, per capita output in 1977 was no higher than in 1957.

Post-Mao economic reforms

Post-Mao rural economic reform began with major price increases for agricultural products in 1979. By 1981 the emphasis had shifted to breaking up collectively tilled fields into land that was contracted out to private families to work. During this time, the size of private plots (land actually owned by individuals) was increased, and most restrictions on selling agricultural products in free markets were lifted. In 1984 much longer-term contracts for land were encouraged (generally 15 years or more), and the concentration of land through subleasing of parcels was made legal. In 1985 the government announced that it would dismantle the system of planned procurements with state-allocated production quotas in agriculture. Peasants who had stopped working the land were encouraged to

find private employment in the countryside or in small towns. They did not obtain permission to move to major cities, however.

The basic thrusts of urban economic reform have been toward integrating China more fully with the international economy; making enterprises responsible for their profits and losses; reducing the state's role in directing, as opposed to guiding, the allocation of resources; shifting investment away from the metallurgical and machine-building industries and toward light and high-technology industries, while retaining an emphasis on resolving the energy, transportation, and communications bottlenecks; creating material incentives for individual effort and a consumer ethos to spur people to work harder; rationalizing the pricing structure; and putting individuals into jobs for which they have specialized training, skills, or talents. At the same time, the state has permitted a private sector to develop and has allowed it to compete with state firms in a number of service areas and, increasingly, in such larger-scale operations as construction.

A number of related measures were established to enhance the incentives for enterprise managers to increase the efficiency of their firms. Replacement of the profit-remission system with tax and contracting systems was designed to reward managers by permitting firms to retain a significant portion of increases in production. Managerial authority within firms has been strengthened, and bonuses have been restored and allowed to grow to substantial proportions. Managers have also been given enhanced authority to hire, fire, and promote workers. Reductions in central-government planning have been accompanied by permission for enterprises to buy and sell surplus goods on essentially a free-market basis. In many cases the prices thus obtained are far higher than for goods produced to meet plan quotas. The state plan has also been used to redirect some resources into the light industrial sector. The state, for example, gives priority in energy consumption to some light industrial enterprises that produce high-quality goods.

The reduction in the scope of mandatory planning is based on the assumption that market forces can more efficiently allocate many resources. This assumption, in turn, requires a rational pricing system that takes into account any and all extant technologies and scarcities. Because extensive subsidies were built into the economic system, however, price reform became an extremely sensitive issue. The fear of inflation also served as a constraint on price reform. Nevertheless, the fact that products produced in excess of amounts targeted in the plan can be sold, in most cases, at essentially free-market prices has created a two-tiered price system that is designed to wean the economy from the administratively fixed prices of an earlier era.

Efforts to create a freer labour market are also part of the overall stress on achieving greater efficiency. As with price reform, tampering with a system that keeps many citizens living more comfortably and securely than would an economically more rational system risks serious repercussions in relations with the public. Changes have proceeded slowly in this sensitive area.

Special economic zones

A decision was made in 1978 to permit direct foreign investment in several small "special economic zones" along the coast. The country lacked the legal infrastructure and knowledge of international practices to make this prospect attractive for many foreign businesses, however. In later years steps were taken to expand the number of areas that could accept foreign investment with a minimum of red tape, and related efforts were made to develop the legal and other infrastructures necessary to make this work well.

This additional effort resulted in making 14 coastal cities and three coastal regions "open" areas for foreign investment. All of these places provide favoured tax treatment and other advantages for the foreign investor. Laws on contracts, patents, and other matters of concern to foreign businesses were also passed in an effort to attract international capital to aid China's development. The largely bureaucratic nature of China's economy, however, poses inherent problems for foreign firms that want to operate in the Chinese environment, and thus the policies to attract foreign capital have had to evolve continually in the direction of presenting more incentives for the foreigner to invest in China.

Search for efficiency

The common threads of these reforms are the search for efficiency and an assumption that management of the economy by large governmental bureaucracies is unlikely to produce this result. The changes in China's economic thinking and strategy since 1978 have been so great—with the potential repercussions for important vested interests so strong—that actual practice inevitably has lagged considerably behind declaratory policy. Notable during this period have been the swings in economic policy between an emphasis on market-oriented reforms and a return to at least partial reliance on centralized planning.

(E.I.U./K.G.L.)

TRANSPORTATION AND COMMUNICATION

Great emphasis has been placed on the development of transport, because it is closely related to the development of the national economy, the consolidation of the national defense system, and the strengthening of national unification. Nevertheless, China's domestic transport system continues to constitute a major constraint on economic growth and the efficient movement of goods and people. Railroads, some still employing steam locomotives, provide the major means for freight haulage, but their capacity cannot meet demand for the shipment of coal and other goods.

Transport-development policy

Since 1949 China's transport and communications policies, influenced by political, military, and economic considerations, have experienced changes of emphasis in different periods. Thus, from 1949 to 1952 the primary concern was to repair existing lines of communication, to give priority to military transport needs, and to strengthen political control. During the First Five-Year Plan new lines were built, while at the same time old lines were improved. During the Great Leap Forward (1958–60) much of the improvement of regional transportation became the responsibility of the general population, and during that time many small railways were constructed. After 1963 emphasis was placed on developing transportation in rural, mountainous, and especially forested areas, in order to help promote agricultural production; simultaneously the development of international communications was energetically pursued, and the scope of ocean transport was broadened considerably.

Initially, as China's railways and highways were mostly concentrated in the coastal regions, access to the interior was difficult. This situation has been partly rectified, as railways and highways have been built in the remote border areas of the northwest and southwest. All of China except for certain counties in Tibet is accessible by rail, road, water, or air.

Railways. Railway construction began in China in 1876. Because railways can conveniently carry a large volume of goods over long distances, they are of especial importance in China's transportation system. All trunk railways in China are under the administration of the Ministry of Railways. The central government operates a major rail network in the Northeast built on a base constructed by the Russians and Japanese during the decades before 1949 and an additional large system inside (that is, to the south or east of) the Great Wall. The framework for the railways inside the wall consists of several north–south and east–west lines.

The small railways

Apart from those operated by the central government, there is also a network of small, state-owned local railways that link mines, factories, farms, and forested areas. The construction of these smaller railways is encouraged by the central government, and technical assistance is provided by the state railway system when it is thought that the smaller railways can stimulate regional economic development.

Coal has long been the principal railway cargo. The rather uneven distribution of coalfields in China makes it necessary to transport coal over long distances, especially between the North and South. The increase in the production of oil and natural gas has made necessary the construction of both pipelines and additional railways.

Since the late 1950s, there has been a change in railway-construction policy. Prior to that time, most attention was

paid to the needs of the eastern half of China, where most of the coal network is found; but since then, more emphasis has been given to extending the rail system into the western provinces and improving the original railway system, including such measures as building bridges, laying double tracks, and using continuous welded rail. In addition, certain important rail links have been electrified.

Since 1960 hundreds of thousands of workers have been mobilized to construct major lines in the northwest and southwest. In the 1970s new lines were extended into previously unopened parts of the country. In the 1980s new regions in the northwest were linked to the national market and opened up for development. The best example was the line built from Lan-chou in Kansu Province westward into the oil fields of the Tsaidam Basin. These projects, which were coordinated on a national level, contrast to the pattern prevailing before World War II, when foreign-financed railroads were built in different places without any attempt at coordination or at standardization of the transport and communications system.

Road networks. The first modern highway in China was built in 1913 in Hunan Province. The highways of China may be divided into three categories: (1) state, provincial, or regional highways of political, economic, or military importance; (2) local highways of secondary importance, operated by counties or communes; (3) special-purpose highways, mostly managed by factories, mines, state farms, forestry units, or the military forces.

The most striking achievement in highway construction has been the road system built on the cold and high Tsinghai–Tibetan plateau. Workers, after overcoming various physical obstacles, within a few years built three of the highest and longest highways in the world, thus markedly changing the transport pattern in the western border regions of China and strengthening the national defense system. Of the three highways, one runs across Szechwan into Tibet; another runs from Tsinghai to Tibet; and the third runs from Sinkiang to Tibet.

The three highways into Tibet

A rural road-building program has aimed at the opening up of commercial routes to the villages to facilitate the transport of locally produced goods. The wide dispersion and seasonal and variable nature of agricultural production, as well as the large numbers of relatively small shipments involved, explain the preferability of trucks for shipping. Similarly, trucks best bring consumer goods, fertilizers, and farm machinery and equipment to rural areas.

When large-scale highway construction was in progress, China also began to develop its petroleum and motor vehicle industries. The first motor vehicle manufacturing plant began to operate during the First Five-Year Plan. By 1970, apart from Tibet and the Hui Autonomous Region of Ningsia, all the provinces and autonomous regions could make their own motor vehicles.

The basis of the local motor vehicle industry is generally simple, usually an extension of motor vehicle repair shops in which vehicles of various types are produced to serve the needs of the locality. Vehicles produced by the large state automotive factories are distributed by the central government to state enterprises and military units. Special vehicles may also be built by the state at these plants. During the 1980s many motor vehicles, especially for passenger transportation, were imported.

Waterways. The high cost of construction prevents railways from being built extensively, and rail transport conditions are often congested. Freight volume carried by highways is limited, and highways are not suitable for moving bulky goods. China's water transport potential is great, but it is still far from being fully developed. Nonetheless, there are more than 68,000 miles of inland waterways open to navigation in China, with many more used for the transport of timber and bamboo. The distribution of waterways is chiefly within central and South China, except for a few navigable streams in the Northeast.

The principal waterways

One of the first goals of the Communist government, upon taking power in 1949, was to establish a national network of waterways. A program of building and refurbishing harbour and port facilities and of dredging river channels was initiated. By 1961 some 15 principal waterways had been opened to navigation, of which the Yangtze, Pearl River, Huai River, Huang Ho (Yellow River), Han River, and Grand Canal had received the most attention. Water transport development continues to receive considerable emphasis. Dredging and improvement of inland waterways have proved an important aid to economic reconstruction, while capital and maintenance costs for water transport are much lower than for railway transport.

The Yangtze, the most important artery in China's waterway network, is also one of the most economically important rivers in the world. Together with its tributaries, it accounts for almost half of the nation's waterways, while the volume of the freight it carries represents about one-third of the total volume carried by river transport. Work undertaken in the mid-1950s to improve the middle course of the Yangtze allowed it to become navigable throughout the year from its mouth to I-pin in Szechwan. When the Yangtze is high in summer, it is navigable from its mouth to as far as Chungking for ships of up to 5,000 tons. By the early 1970s many cable-hauling stations had been established at rapids on the upper course of the Yangtze and of its major tributaries, such as the Wu River. Boats sailing against the current are hauled over the rapids with strong steel cables attached to fixed winches, thus augmenting their loading capacity, increasing speed, and saving time. Such improvements have permitted regular passenger and cargo services to be operated on the Yangtze.

The Hsi River is second in importance only to the Yangtze, being the major water transport artery in South China. Ships of 1,000 tons can sail up the Hsi River to Wu-chou, while shallow-water steamships and wooden boats can sail up the middle and upper courses of the Hsi, Pei, and Tung rivers and their tributaries. The Yangtze and the Hsi are not icebound in winter. Although the Sungari River, flowing across the Manchurian Plain, is navigable for half of its course, it is icebound from November through March; traffic is, however, very busy from April to October. The Amur, Sungari, and Ussuri rivers with their tributaries form a network of waterways totaling about 12,500 miles in length. In the past the Huang Ho was little navigated, especially on its middle and lower courses, but mechanized junks now navigate along the middle course in Honan.

Grand Canal

The Grand Canal, the only major Chinese waterway running from north to south, passes through the basins of the Hai, Huang, Huai, Yangtze, and Ch'ien-t'ang rivers in its 1,100-mile length from Peking to Hang-chou. One of the greatest engineering projects in China, equal in fame to the Great Wall, it is the world's longest artificial waterway; some of its sections follow the natural course of a river,

Cargo barges on the Grand Canal at Suchow, Kiangsu Province.

while other sections have been dug by hand. Work on the canal began as early as the 4th century BC and was completed by the end of the 13th century AD. It forms a north-to-south communications and transport link between the most densely populated areas in China. From the latter part of the 19th century, however, because of political corruption, mismanagement, and flooding from the Huang Ho, it gradually became silted up, and the higher section in Shantung became blocked. The Grand Canal has since been opened to navigation by larger modern craft. The canal is important in the north-south transport of bulky goods, thus facilitating the nationwide distribution of coal and foodstuffs.

Port facilities and shipping. China's 8,700-mile-long coastline is indented by some 100 large and small bays and has some 20 deepwater harbours, most of which are ice-free throughout the year. Coastal shipping is divided into two principal navigation zones, the northern and southern marine districts. The northern district extends north from Amoy to the North Korean border, with Shanghai as its administrative centre. The southern district extends south from Amoy to the Vietnamese border, with Canton as the administrative centre. Most of the oceangoing routes begin from the ports of Lü-ta, Ch'in-huang-tao, T'ang-ku, Tsingtao, Shanghai, Huang-p'u, Chan-chiang, or Hong Kong. Shanghai, the leading port of China from the early 19th century, was eclipsed by Hong Kong when the latter was reincorporated into the country in 1997.

Northern and southern navigation zones

In 1961 China established an Ocean Shipping Company and subsequently signed ocean-shipping agreements with many countries; this laid the foundation for the development of ocean transport. Both before and after that year the Chinese government invested heavily in water transport construction. In addition to new port construction, older ports have been rebuilt and extended. A major effort has also been made to increase mechanization and containerization at major international ports.

Aviation. Aviation development is particularly suited to China, with its extensive territory and varied terrain. Chinese civil aviation has two major categories: air transport, which mainly handles passengers, cargoes, and mail, traveling on both scheduled and nonscheduled routes; and special-purpose aviation, which mainly serves industrial and agricultural production, national defense, and scientific and technological research.

The aims of civil aviation in China have been primarily to extend air routes; to strengthen the link between Peking and other important cities, as well as remote border and interior areas; to develop special-purpose flights serving the needs of agriculture, forestry, and geologic prospecting; and to increase the number of large transport airplanes. With Peking, Shanghai, Canton, and Wu-lu-mu-ch'i as regional centres, an aviation-coordinating agency was formed to link major and local air routes.

In the 1950s international aviation depended mainly on Soviet support; originally all principal international air routes passed through Moscow, where transit was made by Soviet planes. With the deterioration of the Sino-Soviet relationship in the late 1950s, China began to open direct air routes to other places as well. Thus, in addition to the original routes between China and the Soviet Union, North Korea, Mongolia, Vietnam, and Burma (Myanmar), air transport routes were opened to several of China's neighbouring countries, the United States, western Asia, Europe, and Africa. After 1980 the number of air routes grew markedly; the addition of Hong Kong's international air traffic constituted another significant increase.

Airport construction has increased greatly since Peking's first modern civilian airport was built in 1958. That airport was replaced in 1980 by the Capital Airport in Peking, and a new international terminal building was completed at the airport in 1999. New international airports were opened in Hong Kong in 1998 and in Shanghai in 1999, and construction on a new international airport in Canton began in 1998. Airplanes, including various types of military aircraft, have long been made by China. Civil airliners for long-distance flights, however, are still mostly purchased abroad.

Chinese civil air efforts were carried out solely by the Civil Aviation Administration of China from 1949 until the mid-1980s. To improve efficiency and service, regional airlines were then introduced to compete with the airlines operated by the national administration. The Chinese Air Force controls many airfields, and retired Air Force personnel have been the major source of civilian pilots.

Posts and telecommunications. Posts and telecommunications were established rapidly in the 1950s and '60s. By 1952 the posts and telecommunications network centred on Peking, with links to all large cities. Progress was made in improving the postal service under the First Five-Year Plan. Postal service was also developed in rural areas. From 1954 a system of mail delivery by rural postal workers was tried in agricultural cooperatives, and in 1956 this system was extended throughout the country. By 1959 the national postal network was complete.

Postal service

From 1956 telecommunications routes were extended more rapidly. To increase the efficiency of the communication system, the same lines are used for both telegraphic and telephone service, while Teletype and television services also have been added. By 1963 telephone wire had been laid from Peking to the capitals of all provinces, autonomous regions, and large cities, while capitals of all provinces and autonomous regions were connected to the administrative seats of the counties and smaller municipalities and to larger market towns.

Immediately following 1949, telecommunications—by telegraph or telephone—mainly used wire; by the 1970s, however, radio telecommunications were increasingly used. Microwave and satellite transmissions have now become common. In 1956 the first automatic speed Teletype was installed on the Peking-Lhasa line; by 1964 such machines had been installed in most of China's major cities. Radio-television service also was installed in major cities, and radio teleprinters became widely used. Teletype and radio teleprinter technology is being supplanted by increasing access to the Internet. Overall, China's telecommunications services have improved enormously and were enhanced considerably with the acquisition of Hong Kong's highly advanced systems. (C.-S.Ch./K.G.L.)

Administration and social conditions

GOVERNMENT AND PARTY

Despite its size, the People's Republic of China is organized along unitary rather than federal principles. Both the government and the Chinese Communist Party (CCP; Pinyin: Zhongguo Gongchan Dang; Wade–Giles romanization: Chung-kuo Kung-ch'an Tang), moreover, operate "from the top down," arrogating to the "Centre" all powers that are not explicitly delegated to lower levels. To run the country, the government and the CCP have established roughly parallel national bureaucracies extending from Peking down to local levels. These bureaucracies are assisted by various "mass organizations"—trade unions, a youth league, women's associations, writers' and other professional associations, and so forth—that encompass key sectors of the population. These organizations, with their extremely high memberships, have generally served as transmission lines for communicating and uniformly implementing policies affecting their members. No voluntary associations are permitted to function that are wholly independent of CCP and government leadership.

The CCP and government bureaucracies are organized along territorial and functional lines. The territorial organization is based on a number of administrative divisions, with both a CCP committee and a "people's government" in charge of each. These territorial divisions include the national level in Peking (the Centre), 33 provincial-level units (four directly administered cities, five autonomous regions, Hong Kong, Macau, and 22 provinces, excluding Taiwan), more than 150 prefectural bodies, more than 2,000 counties, and numerous cities, towns, and townships. Some larger cities are divided into urban wards and counties. This territorial basis of organization is intended to coordinate and lend coherence to the myriad policies from the Centre that may affect any given locale.

Territorial administration

The functionally based political organization is led by, on the government side, ministries and commissions under

the State Council and, on the CCP side, Central Committee departments. These central-level functional bodies sit atop hierarchies of subordinate units that have responsibility for the sector or issue area under concern. Subordinate functional units typically are attached to each of the territorial bodies.

This complex structure is designed to coordinate national policy (such as that toward the metallurgical industry), assure some coordination of policy on a territorial basis, and enable the CCP to keep control over the government at all levels of the national hierarchy. One unintended result of this organizational approach is that China employs more than 10,000,000 officials—more officials than some countries have citizens.

There are tensions among these different goals, and thus a great deal of shifting has occurred since 1949. During the early and mid-1950s the government's functional ministries and commissions at the Centre were especially powerful. The Great Leap Forward, starting in 1958, shifted authority toward the provincial- and lower-level territorial CCP bodies. During the Cultural Revolution, starting in 1966, much of the political system became so disrupted that the People's Liberation Army (PLA) was called in and assumed control. When the PLA fell under a political cloud, the situation became remarkably fluid and confused for much of the 1970s.

Since then, the general thrust has been toward less detailed CCP supervision of the government and greater decentralization of government authority where possible. But the division of authority between CCP and government and between territorial and functional bodies has remained in a state of flux, as demonstrated by the trend again toward centralization at the end of the 1980s. The Chinese Communist political system still has not become institutionalized enough for the distribution of power among important bodies to be fixed and predictable.

Constitution of 1982

The fourth constitution of the People's Republic of China was adopted in 1982. It vests all national legislative power in the hands of the National People's Congress and its Standing Committee. The State Council and its Standing Committee, by contrast, are made responsible for executing rather than enacting the laws. This basic division of power is also specified for each of the territorial divisions—province, county, and so forth—with the proviso in each instance that the latitude available to authorities is limited to that specified by law.

All citizens over 18 years of age who have not been deprived of their political rights are permitted to vote, and direct popular suffrage is used to choose People's Congress members up to the county level. Above the counties, delegates at each level elect those who will serve at the People's Congress of the next higher level. Were this constitution an accurate reflection of the real workings of the system, the People's Congresses and their various committees would be critical organs in the Chinese political system. In reality, though, they are not.

Actual decision-making authority in China resides in the state's executive organs and in the CCP. At the national level the top government executive organ is the State Council, which is led by the premier. The constitution permits the appointment of vice-premiers, a secretary-general, and an unspecified number of councillors of state and heads of ministries and commissions. The premier, vice-premiers, state councillors, and secretary-general meet regularly as a kind of standing committee, in which the premier has the final decision-making power. This Standing Committee of the State Council exercises major day-to-day decision-making authority, and its decisions de facto have the force of law.

While it is not so stipulated in the constitution, each vice-premier and councillor assumes responsibility for the work of one or more given sectors or issues, such as education, energy policy, or foreign affairs. The leader concerned then remains in contact with the ministries and the commissions of the State Council that implement policy in that area. This division of responsibility permits a relatively small body such as the Standing Committee of the State Council (consisting of fewer than 20 people) to monitor and guide the work of a vast array of major bureaucratic entities. When necessary, of course, the Standing Committee may call directly on additional expertise in its deliberations. The National People's Congress meets roughly annually and does only a little more than to ratify the decisions already made by the State Council.

Parallel to the State Council system is the central leadership of the CCP. The distribution of power among the various organs at the top of the CCP—the Standing Committee of the Political Bureau (Politburo), the Political Bureau itself, and the Secretariat—has varied a great deal, and from 1966 until the late 1970s the Secretariat did not function at all. There is, in any case, a partial overlap of membership among these organs and between these top CCP bodies and the Standing Committee of the State Council. In addition, formally retired elder members of the party have often exercised decisive influence on CCP decision making.

According to the CCP constitution of 1982, the National Party Congress is the highest decision-making body. Since the Party Congress typically convenes only once in five years, the Central Committee is empowered to act when the Congress is not in session. Further, the Political Bureau can act in the name of the Central Committee when the latter is not in session, and the Standing Committee of the Political Bureau guides the work of the Political Bureau. The Secretariat is charged with the daily work of the Central Committee and the Political Bureau. The general secretary presides over the Secretariat and also is responsible for convening the meetings of the Political Bureau and its Standing Committee. The Secretariat works when necessary through several departments (the department for organization, for example, or the department for propaganda) under the Central Committee.

CCP chairmanship

Until 1982 the Chinese Communist Party had a chairmanship that was unique among ruling Communist parties. Mao Zedong (Mao Tse-tung) held this office until his death in 1976, and Hua Guofeng (Hua Kuo-feng) was chairman until his removal from office in June 1981. Hu Yaobang (Hu Yao-pang) then served as party chairman until the post was abolished in September 1982. The decision to redefine the position was part of the effort to reduce the chances of any one leader's again rising to a position above the party, as Mao had done. China's government still has a chairmanship, but the office has very limited power and is largely ceremonial.

The division of power among the leading CCP organs and between them and the State Council is constantly shifting. The Standing Committee of the Political Bureau and the Political Bureau as a whole have the authority to decide on any issue they wish to take up. The Secretariat has also at times played an extremely powerful and active role, meeting more frequently than either the Political Bureau or its Standing Committee and making many important decisions on its own authority. Similarly, the State Council has made many important decisions, but its power is always exercised at the pleasure of the CCP leadership.

Since the late 1970s China has taken a number of initiatives to move toward a more institutionalized system in which the office basically determines the power of its incumbent rather than vice versa, as has often been the case. Thus, for example, the CCP and state constitutions adopted in 1982 (and subsequently amended somewhat) for the first time stipulated a number of positions that confer membership status on the Standing Committee of the Political Bureau. These positions are the head of the Party Military Affairs Commission, the Secretary General of the CCP, the head of the Central Advisory Committee, and the head of the Central Discipline Commission. In addition, for the first time under the stipulations of the constitution, limits of two consecutive terms were placed on the government offices of premier, vice-premier, and state councillor. There were no similar constitutional restrictions on the tenure of incumbents to top CCP positions.

In theory, the Chinese Communist Party sets major policy directions and broadly supervises the implementation of policy to ensure that its will is not thwarted by the state and military bureaucracies. The CCP also assumes major responsibility for instilling proper values in the populace. The government, according to the theory, is responsible

for carrying out CCP policy, making the necessary decisions as matters arise. Of course, this clear division of labour quickly becomes blurred for a number of reasons. For example, only since the late 1970s has a concerted effort been made to appoint different people to the key executive positions in the CCP and the government. Prior to that time, the same individual would head both the CCP committee and the government body in charge of any given area. At the highest levels the premier of the government and the chairman of the party continue to sit on the CCP Political Bureau.

More fundamentally, it is often impossible to clearly separate policy formation and implementation in a huge, complex set of organizations charged with a multiplicity of tasks. The tendency has been for CCP cadres to become increasingly involved in day-to-day operations of the government, until some major initiative was taken by the top national leadership to reverse the trend. While the distinction between the CCP and the government is of considerable significance, therefore, the ruling structure in China can also be viewed from the functional point of view mentioned above. The careers of individual officials may shift among posts in both the CCP and the government, but for most officials all posts are held within one area of concern, such as economics, organization or personnel, security, propaganda, or culture.

ADMINISTRATION

A hierarchy of organization and personnel has been embedded in virtually all CCP and government bodies. Even on the government side, all officials in these personnel departments are members of the CCP, and they follow rules and regulations that are not subject to control by the particular bodies of which they are formally a part. This system has been used to assure higher-level CCP control over the appointments to all key positions in the CCP, government, and other major organizations (enterprises, universities, and so forth).

For much of the period between 1958 and 1978, these personnel departments applied primarily political criteria in making appointments. They systematically discriminated against intellectuals, specialists, and those with any ties or prior experience abroad. From 1978 to 1989, however, official policy was largely the reverse, with ties abroad being valued because of China's stress on "opening the door" to the international community. A good education became an important asset in promoting careers, while a history of political activism counted for less or could even hinder upward mobility. A partial reversion to pre-1978 criteria was decreed in 1989.

Two important initiatives have been taken to reduce the scope of the personnel bureaucracies. First, during 1984 the leaders of various CCP and government bodies acquired far greater power to appoint their own staffs and to promote from among their staffs on their own initiative. The leaders themselves still must be appointed via the personnel system, but most others are no longer fully subject to those dictates. Second, a free labour market has been encouraged for intellectuals and individuals with specialized skills, a policy that could further reduce the power of the personnel bodies.

ARMED FORCES

People's Liberation Army

The People's Liberation Army (PLA) is the unified organization of all Chinese land, sea, and air forces. The history of the PLA is officially traced to the Nan-ch'ang Uprising of Aug. 1, 1927, which is celebrated annually as PLA Day. The PLA is one of the world's largest military forces, with approximately 3,000,000 members. Military service is compulsory for all men who attain the age of 18; women may register for duty in the medical, veterinary, and other technical services. Demobilized servicemen are carried in a ready reserve, which is reinforced by a standby reserve of veterans and by the militia.

The PLA is formally under the command of the central Military Commission of the CCP; there is also an identical commission in the government, but it has no clear independent functions. The CCP commission is far more powerful than the Ministry of National Defense, which operates under the State Council, and it assures continuing CCP control over the armed forces. The political leadership has made a concerted effort to create a professional military force restricted to national defense and to the provision of assistance in domestic economic construction and emergency relief. This conception of the role of the PLA requires the promotion of specialized officers who can understand modern weaponry and handle combined arms operations. Troops around the country are stationed in seven military regions and more than 20 military districts. Despite the drive to modernize the PLA, limited military budgets and other constraints have caused the sophistication of conventional military armaments and of logistics and command-and-control systems to lag behind that of other major military powers.

Public Security forces

The role of the Public Security forces of China began to change in the late 1970s. The definition and designation of what poses a threat to security, for example, were narrowed, and there was a decline in the scope of activities of the security forces. The practice of political suppression, the victims of which once numbered in the tens of millions, was reduced, and in the late 1970s a large (but unknown) number of people were released from labour or other camps run by the Public Security forces. Also, during the 1980s the "open-door" policy toward the outside world led to the adoption of a more relaxed attitude by the Public Security forces regarding their efforts to control and restrict the activities of foreigners in China. By 1990, however, the trend was again toward a stricter policy and tighter controls.

Specific organizational and policy initiatives also have affected the role of the Public Security forces. The trend toward creating a body of codified law and toward establishing a legal system that operates according to that law has in itself reduced the arbitrary power that had been exercised by the Public Security system. (By the 1970s that system had effectively acquired the power to arrest, convict, sentence, and detain any individual without interference from any other "outside" body.) The Public Security Ministry also has relinquished administrative control over counterespionage and economic crimes, which was transferred to a newly organized Ministry of State Security.

JUSTICE

Legal apparatus

The legal apparatus that existed before the changes made during the Cultural Revolution has been resurrected. The State Council again has a Ministry of Justice, and procuratorial organs and a court system have been reestablished. The legal framework for this system has been provided through the adoption of various laws and legal codes. For the first time, the law provides that there should be no discrimination among defendants based on their class origin. China has also reestablished a system of lawyers.

The actual functioning of this legal apparatus, however, continues to be adversely affected by a shortage of qualified personnel and by deeply ingrained perspectives that do not accord the law priority over the desires of political leaders. Thus, for example, when the top CCP leadership ordered a severe crackdown on criminal activity in 1983, thousands were arrested and executed without fully meeting the requirements of the newly passed law on criminal procedures. That law was subsequently amended to conform more closely with the actual practices adopted during the crackdown.

HEALTH AND WELFARE

The Chinese government faces a mammoth task in trying to provide medical and welfare services adequate to meet the basic needs of the immense number of Chinese people whose per capita income and caloric intake are far below the world's average. The medical system, moreover, labours under the tension of whether to stress quality of care or to spread scarce medical resources as widely as possible. In addition, there has been repeated debate over the relative balance that should be struck between the use of Western and traditional Chinese medicine. While the Cultural Revolution pushed the balance toward widespread minimum care with great attention paid to traditional medicine, policy after the late 1970s moved in

the other direction on both issues. The Ministry of Public Health of the State Council oversees the health-services system, which includes a substantial rural collective sector but almost no private sector. All the major medical facilities are run by the government.

Life expectancy

The health of the Chinese populace has improved considerably since 1949. Average life expectancy has gone up about three decades and now ranks nearly at the level of that in advanced industrial societies. Many communicable diseases, such as plague, smallpox, cholera, and typhus, have either been wiped out or brought under control. Chinese statistics also indicate that the incidences of malaria and schistosomiasis have declined by 90 percent and 80 percent, respectively, since 1949.

As evaluated on a per capita basis, China's health facilities remain unevenly distributed. Only slightly more than half of the country's medical and health personnel work in rural areas, where approximately four-fifths of the population resides. The doctors of Western medicine, who constitute about one-sixth of the total medical personnel, are even more concentrated in urban areas. Similarly, close to two-thirds of the country's hospital beds are located in the cities.

China has a health insurance system that provides virtually free coverage for people employed in urban state enterprises and relatively inexpensive coverage for their families. The situation for workers in the rural areas or in urban employment outside the state sector is far more varied. There are some cooperative health-care programs, but their voluntary nature produced a decline in membership from the late 1970s.

The severest limitation on the availability of health services, however, appears to be an absolute lack of resources, rather than discrimination in access based on the ability of individuals to pay. An extensive system of paramedical care has been fostered as the major medical resource available to most of the rural population, but the care thus provided has been found to be of quite uneven quality. The paramedical system feeds patients into the more sophisticated commune-level and county-level hospitals when they are available.

Changes in the leading causes of death reflect the longer life span and improved living conditions that have developed in China since 1949. By the mid-1990s the major causes had become pulmonary and cerebrovascular diseases, malignant tumours, and cardiac disease. Severe environmental pollution has become a major health hazard in several parts of the country.

Because a large percentage of what in the West would be considered public welfare obligations is in China the responsibility of factories, offices, and rural collectives and families, the real level of "welfare" spending and the strengths and weaknesses of the welfare system are difficult to gauge. Little statistical information is available that could help clarify the situation. The state provides pensions for retirees from state enterprises and official service, but this includes only a small percentage of the total workforce. The state's welfare resources are heavily concentrated in the urban areas, where they include subsidies for housing, medical care, education, and some foods. In the cities the level of subsidized services, though, depends largely on the nature and conditions of the unit in which a person works. Unemployed individuals are typically taken care of by their working relatives, and all Chinese citizens have a legal obligation to care for their elderly parents. There is a small number of old-age homes for the elderly who have no children or other relatives to support them.

In the rural areas much of the responsibility for welfare is left to the local collective units, the resources of which have declined since the late 1970s. China's rural collectives are supposed to provide for their poor, but the actual level of services varies greatly depending on both the financial standing of the locality and the inclinations of the villagers. The Chinese government does allocate emergency relief to areas that have suffered from natural disasters (including crop failures). Generally, the Ministry of Civil Affairs of the State Council assumes primary responsibility for administering the government's portion of China's welfare system.

EDUCATION

The educational system in China is a major vehicle for both inculcating values in and teaching needed skills to its people. Traditional Chinese culture attached great importance to education as a means of enhancing a person's worth and career. In the early 1950s the Chinese Communists worked hard to increase the country's rate of literacy, an effort that won them considerable support from the population. By the end of that decade, however, the government could no longer provide jobs adequate to meet the expectations of those who had acquired some formal schooling. Other pressing priorities squeezed educational budgets, and, of course, the anti-intellectualism inherent in the more radical mass campaign periods affected the status and quality of the educational effort. These conflicting pressures made educational policy a sensitive barometer of larger political trends and priorities. The shift to rapid and pragmatic economic development as the overriding national goal in the late 1970s quickly affected China's educational system.

China's school system

The Chinese educational structure provides for six years of primary school, three years each of lower middle school and upper middle school, and four years in the standard university curriculum. All urban schools are financed by the state, while rural schools depend far more heavily on their own financial resources. Official policy stresses scholastic achievement, with particular emphasis on the natural sciences. A significant effort is made to enhance vocational training opportunities for students who do not attend a university. The quality of education that is available in the cities is generally far higher than that in the countryside, where relatively few students acquire even a secondary education.

The overall trend in Chinese education is toward fewer students and higher scholastic standards, resulting in a steeply hierarchical educational system. Only about one-third of the nation's primary school students gain access to some secondary education, while less than 2 percent ever attend a regular university. Only the best students go beyond a primary school, and many secondary schools are closed because of a lack of students. For the overwhelming majority of students, admission to a university since 1977 has been based on competitive nationwide examinations, and attendance at a university is usually paid for by the government. In return, a university student has had to accept the job provided by the state upon graduation.

The system developed in the 1950s of setting up "key" urban schools that were given the best teachers, equipment, and students was reestablished in the late 1970s. The inherently elitist values of such a system put enormous pressure on secondary-school administrators to improve the rate at which their graduates passed tests for admission into universities.

Major universities

Six universities, all administered directly by the State Education Commission in Peking, are the flagships of the Chinese higher educational system. They are Peking University, the leading nontechnical university; Ch'ing-hua University, an institution that is oriented primarily toward engineering; People's University of China, the only major university founded after 1949; Nan-k'ai University in Tientsin, which is especially strong in the social sciences; Fu-tan University, a comprehensive institution in Shanghai; and Sun Yat-sen (Chung-shan) University in Canton, the principal university of South China. In addition, every province has a key provincial university, and there are hundreds of other technical and comprehensive higher educational institutions. The University of Hong Kong is the oldest school in Hong Kong.

The damage done to China's human capital by the ravages of the Great Leap Forward and, especially, by the Cultural Revolution was so great that it has taken years to make up the loss. After the 1970s, however, China's educational system increasingly trained individuals in technical skills so that they could fulfill the needs of the advanced, modern sector of the economy. The social sciences and humanities also receive more attention than in earlier years, but the base in those disciplines is relatively weak—many leaders still view them with suspicion—and the resources devoted to them are thin. (K.G.L.)

Cultural life

Chinese culture is remarkable for its duration and diversity. Skeletal remains and stone implements date to the Paleolithic stage of cultural development, from the 29th to the 17th millennium BC. Decorated artifacts, primarily marked pottery vessels, have been found in dozens of Incipient Neolithic and Neolithic sites, dating from the 12th to the 2nd millennium BC.

Yang-shao and Lung-shan pottery

Chinese Neolithic pottery shapes and types are mostly classified into two families—the earlier Yang-shao ware from the central Chung-yüan region, characterized by geometric painted decorations, and the later Lung-shan ware, primarily from the Northeast but also found in the Chung-yüan area. Lung-shan ware is unpainted and is elevated from the ground on a circular foot or tripod legs.

The Bronze Age includes the first historically verified dynasty, the Shang (18th–12th century BC), and China's first written records. The Late Shang is well known from oracle bones recovered from the site of the last Shang capital near An-yang. The bones are turtle plastrons and ox scapulae with inscribed texts, used by the Shang kings in a highly regularized system of ritual divination and sacrifice aimed at securing the support of the ruler's deceased ancestors. Through their use, writing became linked to authority in a way that endured throughout premodern Chinese history. During the Shang and Chou (1111–255 BC) dynasties the art of bronze casting became highly developed. Finely cast and richly decorated pieces included cooking and serving vessels, bells, drums, weapons, and door fittings.

The written language

The written language is central to China's culture. Ideographic inscriptions have been found on pottery dating to about 4000 BC, and written Chinese has developed continuously since the Late Shang period. Chinese culture is inextricably bound up with the writing system in three ways. First, writing is the medium for preserving and disseminating culture. China's word for culture (*wen-hua*) means "to become literate." Second, command of the writing system distinguishes the Chinese and their culture, seen as the centre of the world, from all non-Chinese peoples, categorized by the Chinese as "barbarians." Third, culture and the writing system are inseparably linked to statecraft: a command of writing and knowledge of the written tradition were requisite skills for holding office. Thus, from the Shang oracle bones to the products of the modern printing press, culture in the form of written works has been instrumental in developing political thought and governance.

The oldest art forms in China are music and dance. A 5,000-year-old pottery bowl from Tsinghai Province is painted with a ring of 15 dancers, adorned in headdresses and sashes and stepping in unison. Music played an important role in early Chinese ritual and statecraft. Bronze bells were instruments of investiture and reward. A bronze bell set from the ancient state of Tseng in Hupeh, interred *c.* 430 BC, contains 64 bells, each of which produces two distinct, tuned strike notes. More than 120 instruments were unearthed from the same tomb, including stringed zithers, mouth organs, flutes, drums, and stone chimes. Music and related rituals helped to provide a structure for activities in the courts of rulers at all levels in the feudal hierarchy.

The *Shih Ching*

The *Shih Ching* ("Classic of Poetry"), an anthology of poetry given definitive form in about 500 BC, is one of China's oldest classics and contains 305 folk songs and ritual psalms. Although the T'ang dynasty (AD 618–907) is called the Golden Age of Chinese poetry, having produced the poets Tu Fu and Li Po, there are poets of renown from every dynasty, and the writing of poetry was practiced by most well-educated Chinese for both personal and social reasons.

China's tradition of historical narrative is also unsurpassed in the world. Twenty-five dynastic histories preserve a unique record from the unverified Hsia dynasty (22nd–19th/18th century BC) to the Ch'ing (AD 1644–1911/12), and sprawling historical romances have been a mainstay in the reading of the educated since the spread of printing in the 11th and 12th centuries AD.

The May Fourth Movement (1917–21) attacked much of this great literary and cultural tradition, viewing it as a source of China's weakness. Students and faculty at Peking University abandoned the more demanding literary language and created a new popular fiction, written in a more accessible colloquial language on themes from ordinary life. Literary culture continued to be a subject of intense debate. Mao Zedong, who composed poetry in both contemporary and traditional styles, proclaimed in his talks at Yen-an in 1942 that art must serve politics. Throughout the following decades, writers received both admiration and ridicule. Indeed, the fate of most important writers was closely linked to the vicissitudes of national politics from the 1950s onward. Only in the mid-1980s did writers again begin to enjoy some official tolerance of "art for art's sake."

Painting and calligraphy, like poetry, were the domain of the elite, and most educated Chinese traditionally boasted of some competence in them. There are early anonymous and folk-oriented paintings on tomb and cave walls, and many works are known from the Han dynasty (206 BC–AD 220). Fine-art painters are known by name from as early as the 6th century AD from historical records and serially copied versions of their works. Chinese painting is predominantly of landscapes, done in black pine-soot ink on fine paper or silk, occasionally with the addition of faint colour washes. The most vigorous period for landscape painting spanned the years from the Sung dynasty (960–1279) to the Ming (1368–1644).

Calligraphy rivals painting as a fine art in China, and paintings are often captioned with artfully written poems. Calligraphy reveals the great fondness the Chinese have for their written characters, and it ranges in style from meticulously and laboriously scribed "seal" characters to flamboyant and unconstrained "grass" characters. Calligraphy, as painting, is prized for a number of abstract aesthetic qualities, described by such terms as "balance," "vitality," "energy," "bones," "wind," and "strength."

Painting has undergone numerous style changes in the 20th century. Before 1949 painters such as Ch'i Pai-shih (1863–1957) developed distinct new styles that internationalized traditional Chinese aesthetics. After 1949 pressure for socialist realism made painters shift their focus to such subjects as factory scenes, peasant villages, and convoys of tour buses. But with the liberalization of the arts that followed Mao's death in 1976, more traditional values reasserted themselves.

Chinese sculpture and carving

Sculpture and carving date to the Chou dynasty (*c.* 1111–255 BC) or earlier. Tombs frequently contained burial dolls, said to have been made to replace live sacrificial victims, and many early jade carvings are related to burial practices and include body orifice stoppers and bangle bracelets. Of all the arts, sculpture received the greatest boost from the introduction of Buddhism to China during the Han dynasty and from the spread of Buddhism during the Six Dynasties (AD 220–589) and T'ang periods. Statues and carved reliefs of Buddhas and *bodhisattva*s were made by the thousands and, along with cave paintings at prominent sites like Tun-huang, Kansu Province, represent the pinnacle of Chinese religious art.

Chinese art and artifacts have found their way into various collections around the world. The most important collection of fine arts is in the National Palace Museum in Taipei, Taiwan, the bulk of the superb traditional palace collection having been ferried across the Taiwan Strait during the Nationalist retreat in 1948–49. Excellent collections of Chinese painting, calligraphy, and bronzes are found in such museums as the Freer Gallery of Art of the Smithsonian Institution in Washington, D.C.; the Fogg Art Museum at Harvard University; and the Museum of Fine Arts, Boston. Significant collections remain in major museums in Peking, Shanghai, Nanking, and Wuhan. Since the 1950s, new archaeological discoveries have filled China's provincial and local museums with fabulous treasures, and new facilities have been constructed for the study and display of these artifacts. Especially notable is the life-size terra-cotta army of the first Ch'in emperor, Shih huang-ti. The army, complete with soldiers, horses, and chariots, was discovered in an enormous under-

ground vault near Sian, in Shensi Province. Many of its figures have been painstakingly removed and placed on public display.

Theatre is the most important popular art in China. It originated in early religious dances, performed at festivals to exorcise demons, reenact important historical events, or prepare for harvest, hunting, or warfare. Urban storytelling and theatrical genres are well documented from the Sung dynasty but are known to have matured during the Yüan dynasty (1206–1368). Yüan dramas, or operas as they are more accurately called, consisted of virtuoso song and dance organized around plots on historical or contemporary themes. The operas were performed in special theatres, with elegant costumes and decorated stages. From Yüan drama later forms developed, including contemporary Cantonese and Peking operas, that feature song and dance, elaborate costumes and props, and displays of martial arts and acrobatics.

During the Cultural Revolution, an enormous number of cultural treasures of inestimable value were seriously damaged or destroyed and the practice of many arts and crafts was prohibited. Since the early 1980s, however, official repudiation of those policies has been complemented by vigorous efforts to renew China's remarkable cultural traditions. The loosening of many restrictions has also rejuvenated many art forms previously devoted almost exclusively to propaganda. China's "Fifth Generation Cinema," for example, is known for such outstanding young film directors as Chang Yi-mou, who have highlighted themes of social and political oppression. (K.J.DeW.)

Chinese culture can also be understood through the vehicle of food. Chinese cuisine, like Chinese philosophy, is organized along Taoist principles of opposition and change: hot is balanced by cold, spicy by mild, fresh by cured. The cooking of Szechwan in southwestern China is distinguished by the use of hot peppers, which are indigenous to the region. The lush southern interior of the country prizes fresh ingredients; Cantonese cuisine in particular is a symphony of subtle flavors from just-picked vegetables and lightly cooked meats. No matter what the region, foods of all kinds are viewed as an accompaniment to grains, the staple of the Chinese diet.

Sports and recreation

Physical exercise is also a staple of Chinese culture. Millions gather daily at dawn to practice martial arts (notably T'ai Chi ch'uan), wield swords in a graceful ballet, or (among women) perform a synchronized dance of pliés and turns. Acrobatics are especially popular and have enjoyed a new surge of interest since 1950, when the China Acrobatic Troupe was organized in Peking. From it have grown satellite companies in Shanghai, Chungking, Shenyang, Wu-han, and Lü-ta. Imported sports such as basketball, baseball, and football (soccer) have become hugely popular, drawing millions of participants and spectators. Of China's indigenous forms of sport, the martial arts have the longest history by far, originating some two thousand years ago when contending warlords, bandits, and foreign invaders controlled large portions of China and forbade the populace to own weapons.

China has become one of the dominant nations in international sports competitions. It began regular participation in the Olympic Games at the 1980 Winter Games and has had particular success at the Summer Games in such sports as gymnastics, swimming, and diving. (Ed.)

For statistical data on the land and people of China, see the *Britannica World Data* section in the BRITANNICA BOOK OF THE YEAR.

HISTORY

Prehistory

ARCHAEOLOGY IN CHINA

The practice of archaeology in China has been strongly influenced by China's modern history. The intellectual and political reformers of the 1920s challenged the historicity of the legendary inventors of Chinese culture, such as Shen Nung, the divine farmer, and Huang Ti, the Yellow Emperor. At the same time, scientific study of the prehistoric period was being sponsored by archaeologists and paleoanthropologists from western Europe and North America. The establishment of the Academia Sinica (Chinese Academy of Sciences) in 1928 enabled Chinese scholars to study Chinese archaeology for themselves, but the eruption of the Sino-Japanese War in 1937 made excavation difficult. That some researchers found themselves, with their collections, in Taiwan after 1949 and that much archaeology in the People's Republic of China was conducted within a Marxist framework further demonstrate archaeology's links to politics. The waning of the Cultural Revolution in the 1970s permitted the resumption of archaeological excavation and publication. A modernizing nation began to produce scholarship, increasingly informed by scientific analysis, in a quantity and quality commensurate with its size and its traditions of learning.

EARLY HUMANS

The fossil record in China promises fundamental contributions to the understanding of human origins. There is considerable evidence of *Homo erectus* by the time of the Lower Paleolithic (the Paleolithic Period began *c.* 2,500,000 years ago and ended 10,000 years ago) at sites such as Lan-t'ien, Shensi; Ho-hsien, Anhwei; Yüan-mou, Yunnan; and, the most famous, that of so-called Peking man at Chou-k'ou-tien, Peking Municipality. The Lower Cave at the last site has yielded evidence of intermittent human use from *c.* 460,000 to 230,000 years ago. Many caves and other sites in Anhwei, Hopeh, Honan, Liaoning, Shantung, Shansi, and Shensi in North China and in Kweichow and Hupeh in the South suggest that *H. erectus* achieved wide distribution in China. Whether *H. erectus pekinensis* intentionally used fire and practiced ritual cannibalism are matters under debate.

Peking man

Significant *Homo sapiens* cranial and dental fragments have been found together with Middle Paleolithic artifacts at Ting-ts'un, Shansi; Ch'ang-yang, Hupeh; Ta-li, Shensi; Hsü-chia-yao, Shansi; and Ma-pa, Kwangtung. Morphological characteristics such as the shovel-shaped incisor, broad nose, and mandibular torus link these remains to the modern Chinese. Few archaeological sites have been identified in the South.

A number of widely distributed *H. erectus* sites dating from the upper Pleistocene manifest considerable regional and temporal diversity. Upper Paleolithic sites are numerous in North China. Thousands of stone artifacts, most of them small (called microliths), have been found, for example, at Hsiao-nan-hai, near An-yang, Honan; Shuo-hsien and Ch'in-shui, Shansi; and Yang-yüan, Hopeh. These findings suggest an extensive microlith culture in North China. Hematite, a common iron oxide ore used for colouring, was found scattered around skeletal remains in the Upper Cave at Chou-k'ou-tien (*c.* 10th millennium BC) and may represent the first sign of human ritual.

NEOLITHIC PERIOD

The complex of developments in stone tool technology, food production and storage, and social organization that is often characterized as the "Neolithic Revolution" was in progress in China by at least the 6th millennium BC. Developments in the Chinese Neolithic were to establish some of the major cultural dimensions of the subsequent Bronze Age.

Climate and environment. Although the precise nature of the paleoenvironment is still in dispute, temperatures in Neolithic China were probably some 4° to 7° F (2° to 4° C) warmer than they are today. Rainfall, although more abundant, may have been declining in quantity. The Tsinling Mountains in northwest China separated the two phytogeographical zones of North and South China, while the absence of such a mountain barrier farther east encouraged a more uniform environment and the freer movement of Neolithic peoples about the North China

Plain. East China, particularly toward the south, may have been covered with thick vegetation, some deciduous forest, and scattered marsh. The Loess Plateau in the northwest is thought to have been drier and even semiarid, with some coniferous forest growing on the hills and with brush and open woodland in the valleys.

Millet and rice crops

Food production. The primary Neolithic crops, domesticated by the 5th millennium BC, were drought-resistant millet (usually *Setaria italica*), grown on the eolian or alluvial loess soils of the northwest and the north, and glutenous rice (*Oryza sativa*), grown in the wetlands of the southeast. These staples were supplemented by a variety of fruits, nuts, legumes, vegetables, and aquatic plants. The main sources of animal protein were pigs, dogs, fish, and shellfish. By the Bronze Age millet, rice, soybeans, tea, mulberries, hemp, and lacquer had become characteristic Chinese crops. That most, if not all, of these plants were native to China indicates the degree to which Neolithic culture developed indigenously. The distinctive cereal, fruit, and vegetable complexes of the northern and southern zones in Neolithic and early historic times suggest, however, that at least two independent traditions of plant domestication may have been present.

The stone tools used to clear and prepare the land reveal generally improving technology. There was increasing use of ground and polished edges and of perforation. Regional variations of shape included oval-shaped axes in central and northwest China, square- or trapezoid-shaped axes in the east, and axes with stepped shoulders in the southeast. By the Late Neolithic a decrease in the proportion of stone axes to adzes suggests the increasing dominance of permanent agriculture and a reduction in the opening up of new land. The burial in high-status graves of finely polished, perforated stone and jade tools such as axes and adzes with no sign of edge wear indicates the symbolic role such emblems of work had come to play by the 4th and 3rd millennia.

Major cultures and sites. There was not one Chinese Neolithic but a mosaic of regional cultures whose scope and significance are still being determined. Their location in the area defined today as China does not necessarily mean that all the Neolithic cultures were Chinese or even proto-Chinese. Their contributions to the Bronze Age civilization of the Shang, which may be taken as unmistakably Chinese in both cultural as well as geographical terms, need to be assessed in each case. In addition, the presence of a particular ceramic ware does not necessarily define a cultural horizon; and transitional phases, both chronological and geographical, cannot be discussed in detail in the following paragraphs.

Incipient Neolithic. Study of the historical reduction of the size of human teeth suggests that the first human beings to eat cooked food did so in South China. The southern sites of Hsien-jen-tung in Kiangsi and Tseng-p'i-yen in Kwangsi have yielded artifacts from the 10th to the 7th millennium BC that include low-fired, cord-marked sherds with some incised decoration and mostly chipped stone tools; these pots may have been used for cooking and storage. Pottery and stone tools from shell middens in South China also suggest Incipient Neolithic occupations. These early southern sites may have been related to the Neolithic Bac-Son culture in Vietnam; connections to the subsequent Neolithic cultures of northwest and North China have yet to be demonstrated.

Sixth millennium BC. Two major cultures can be identified in the northwest: Lao-kuan-t'ai, in eastern and southern Shensi and northwestern Honan, and Ta-ti-wan I—a development of Lao-kuan-t'ai culture—in eastern Kansu and western Shensi. In these cultures pots were low-fired, sand-tempered, and mainly red in colour, and bowls with three stubby feet or ring feet were common. The painted bands of this pottery may represent the start of the Painted Pottery culture.

In North China the people of P'ei-li-kang (north central Honan) made less use of cord marking and painted design on their pots than did those at Ta-ti-wan I; the variety of their stone tools, including sawtooth sickles, indicates the importance of agriculture. The Tz'u-shan potters (southern Hopeh) employed more cord-marked decoration and made a greater variety of forms, including basins, cups, serving stands, and pot supports. The discovery of two pottery models of silkworm chrysalides and 70 shuttle-like objects at a 6th-millennium-BC site at Nan-yang-chuang (southern Hopeh) suggests the early production of silk, the characteristic Chinese textile.

Tz'u-shan pottery

Fifth millennium BC. The lower stratum of the Pei-shou-ling culture is represented by finds along the Wei and Ching rivers; bowls, deep-bodied jugs, and three-footed vessels, mainly red in colour, were common. The lower stratum of the related Pan-p'o culture, also in the Wei River drainage area, was characterized by cord-marked red or red-brown ware, especially round and flat-bottomed bowls and pointed-bottomed amphorae. The Pan-p'o inhabitants lived in semisubterranean houses and were supported by a mixed economy of millet agriculture, hunting, and gathering. The importance of fishing is confirmed by designs of stylized fish painted on a few of the bowls and by numerous hooks and net sinkers.

Pei-shou-ling, Pan-p'o, and Hou-kang cultures

In the east by the start of the 5th millennium the Pei-hsin culture in central and southern Shantung and northern Kiangsu was characterized by fine clay or sand-tempered pots decorated with comb markings, incised and impressed designs, and narrow, appliquéd bands. Artifacts include many three-legged, deep-bodied tripods, goblet-like serving vessels, bowls, and pot supports. Hou-kang (lower stratum) remains have been found in southern Hopeh and central Honan. The vessels, some finished on a slow wheel, were mainly red coloured and had been fired at high heat. They include jars, tripods, and round-bottomed, flat-bottomed, and ring-footed bowls. No pointed amphorae have been found, and there were few painted designs. A characteristic red band under the rim of most gray-ware bowls was produced during the firing process.

Archaeologists have generally classified the lower strata of Pei-shou-ling, Pan-p'o, and Hou-kang cultures under the rubric of Painted Pottery (or, after a later site, Yang-shao) culture, but two cautions should be noted. First, a distinction may have existed between a more westerly, Wei Valley culture (early Pei-shou-ling and early Pan-p'o) that was rooted in the Lao-kuan-t'ai culture and a more easterly one (Pei-hsin, Hou-kang) that developed from the P'ei-li-kang and Tz'u-shan cultures. Second, since only 2 to 3 percent of the Pan-p'o pots were painted, the designation Painted Pottery culture seems premature.

Ho-mu-tu site

In the region of the lower Yangtze River the Ho-mu-tu site in northern Chekiang has yielded caldrons, cups, bowls, and pot supports made of porous, charcoal-tempered black pottery. The site is remarkable for its wooden and bone farming tools, the bird designs carved on bone and ivory, the superior carpentry of its pile dwellings (a response to the damp environment), a wooden weaving shuttle, and the earliest lacquer ware and rice remains yet reported in the world (*c.* 5000 to 4750 BC). The Ch'ing-lien-kang culture, which succeeded that of Ho-mu-tu in Kiangsu, northern Chekiang, and southern Shantung, was characterized by ring-footed and flat-bottomed pots, *kuei* pouring vessels, tripods (common north of the Yangtze), and serving stands (common south of the Yangtze). Early fine-paste red ware gave way in the later period to fine-paste gray and black ware. Polished stone artifacts include axes and spades, some perforated, and jade ornaments. Another descendant of Ho-mu-tu culture was that of Ma-chia-pang, which had close ties with the Ch'ing-lien-kang culture in southern Kiangsu, northern Chekiang, and Shanghai. In southeastern China a cord-marked pottery horizon, represented by the site of Fu-kuo-tun on the island of Quemoy, existed by at least the early 5th millennium. The suggestion that some of these southeastern cultures belonged to an Austronesian complex remains to be fully explored.

Fourth and third millennia BC. A true Painted Pottery culture developed in the northwest partly from the Wei Valley and Pan-p'o traditions of the 5th millennium. The Miao-ti-kou I horizon, dated from the first half of the 4th millennium, produced burnished bowls and basins of fine red pottery, some 15 percent of which were painted, generally in black, with dots, spirals, and sinuous lines. It was succeeded by a variety of Ma-chia-yao cultures (late

4th to early 3rd millennium) in eastern Kansu, eastern Tsinghai, and northern Szechwan. Thirty percent of Ma-chia-yao vessels were decorated on the upper two-thirds of the body with a variety of designs in black pigment; multiarmed radial spirals, painted with calligraphic ease, were the most prominent. Related designs involving sawtooth lines, gourd-shaped panels, spirals, and zoomorphic stick figures were painted on pots of the Pan-shan (mid-3rd millennium) and Ma-ch'ang (last half of 3rd millennium) cultures. Some two-thirds of the pots found in the Ma-ch'ang burial area at Liu-wan in Tsinghai, for example, were painted. In the North China Plain, Ta-ho culture sites contain a mixture of Miao-ti-kou and eastern, Ta-wen-k'ou vessel types (see below), indicating that a meeting of two major traditions was taking place in this area in the late 4th millennium.

In the northeast the Hung-shan culture (4th millennium and probably earlier) was centred in western Liaoning and eastern Inner Mongolia. It was characterized by small bowls (some with red tops), fine red-ware serving stands, painted pottery, and microliths. Numerous jade amulets in the form of birds, turtles, and coiled dragons reveal strong affiliations with the other jade-working cultures of the east coast, such as Liang-chu (see below).

In east China the Liu-lin and Hua-t'ing sites in northern Kiangsu (first half of 4th millennium) represent regional cultures that derived, in large part, from that of Ch'ing-lien-kang. Upper strata also show strong affinities with contemporary Ta-wen-k'ou sites in southern Shantung, northern Anhwei, and northern Kiangsu. Ta-wen-k'ou culture (mid-5th to at least mid-3rd millennium) is characterized by the emergence of wheel-made pots of various colours, some of them remarkably thin and delicate; vessels with ring feet and tall legs (such as tripods, serving stands, and goblets); carved, perforated, and polished tools; and ornaments in stone, jade, and bone. The people practiced skull deformation and tooth extraction. Mortuary customs involved ledges for displaying grave goods, coffin chambers, and the burial of animal teeth, pig heads, and pig jawbones.

Ta-wen-k'ou culture

In the middle and lower Yangtze River valley during the 4th and 3rd millennia the Ta-hsi and Ch'ü-chia-ling cultures shared a significant number of traits, including rice production, ring-footed vessels, goblets with sharply angled profiles, ceramic whorls, and black pottery with designs painted in red after firing. Characteristic Ch'ü-chia-ling ceramic objects not generally found in Ta-hsi sites include eggshell-thin goblets and bowls painted with black or orange designs; double-waisted bowls; tall, ring-footed goblets and serving stands; and many styles of tripods. Admirably executed and painted clay whorls suggest a thriving textile industry. The chronological distribution of ceramic features suggests a transmission from Ta-hsi to Ch'ü-chia-ling, but the precise relationship between the two cultures has been much debated.

The Ma-chia-pang culture in the T'ai Lake basin was succeeded during the 4th millennium by that of Sung-tse. The pots, increasingly wheel-made, were predominantly clay-tempered gray ware. Tripods with a variety of leg shapes, serving stands, *kuei* pitchers with handles, and goblets with petal-shaped feet were characteristic. Ring feet were used, silhouettes became more angular, and triangular and circular perforations were cut to form openwork designs on the short-stemmed serving stands. A variety of jade ornaments, a feature of Ch'ing-lien-kang culture, has been excavated from Sung-tse burial sites.

Sites of the Liang-chu culture (from the last half of the 4th to the last half of the 3rd millennium) have generally been found in the same area. The pots were mainly wheel-made, clay-tempered gray ware with a black skin and were produced by reduction firing; oxidized red ware was less prevalent. Some of the serving stand and tripod shapes had evolved from Ma-chia-pang prototypes, while other vessel forms included long-necked *kuei* pitchers. The walls of some vessels were black throughout, eggshell-thin, and burnished, resembling those found in Late Neolithic sites in Shantung (see below). Extravagant numbers of highly worked jade *pi* disks and *ts'ung* tubes were placed in certain burials, such as one at Ssu-tun (southern Kiangsu) that contained 57 of them. Liang-chu farmers had developed a characteristic triangular shale plow for cultivating the wet soils of the region. Fragments of woven silk from *c.* 3000 BC have been found at Ch'ien-shang-yang (northern Chekiang). Along the southeast coast and on Taiwan the Ta-p'en-k'eng corded-ware culture emerged during the 4th and 3rd millennia. This culture, with a fuller inventory of pot and tool types than had previously been seen in the area, developed in part from that of Fu-kuo-tun but may also have been influenced by cultures to the west and north, including Ch'ing-lien-kang, Liang-chu, and Liu-lin. The pots were characterized by incised line patterns on neck and rim; low, perforated foot rims; and some painted decoration.

Regional cultures of the Late Neolithic. By the 3rd millennium BC the regional cultures in the areas discussed above showed increased signs of interaction and even convergence. That they are frequently referred to as varieties of the Lung-shan culture (*c.* 2500–2000 BC) of east central Shantung—characterized by its lustrous, eggshell-thin black ware—suggests the degree to which these cultures are thought to have experienced eastern influence. That influence, diverse in origin and of varying intensity, entered the North China Plain from sites such as Ta-tun-tzu and Ta-wen-k'ou to the east and also moved up the Han River from the Ch'ü-chia-ling area to the south. A variety of eastern features are evident in the ceramic objects of the period, including use of the fast wheel, unpainted surfaces, sharply angled profiles, and eccentric shapes. There was a greater production of gray and black, rather than red, ware; componential construction was emphasized, in which legs, spouts, and handles were appended to the basic form (which might itself have been built sectionally). Greater elevation was achieved by means of ring feet and tall legs. Ceramic objects included three-legged tripods, steamer cooking vessels, *kuei* pouring pitchers, serving stands, fitted lids, cups and goblets, and asymmetrical *pei hu* vases for carrying water that were flattened on one side to lie against a person's body. In stone and jade objects, eastern influence is evidenced by perforated stone tools and ornaments such as *pi* disks and *ts'ung* tubes used in burials. Other burial customs involved ledges to display the goods buried with the deceased and large wooden coffin chambers. In handicrafts, an emphasis was placed on precise mensuration in working clay, stone, and wood. Although the first, primitive versions of the eastern ceramic types may have been made, on occasion, in the North China Plain, in virtually every case these types were elaborated in the east and given more precise functional definition, greater structural strength, and greater aesthetic coherence. It was evidently the mixing in the 3rd and 2nd millennia of these eastern elements with the strong and extensive traditions native to the North China Plain—represented by such Late Neolithic sites as Ko-la-wang-ts'un (near Cheng-chou), Wang-wan (near Lo-yang), Miao-ti-kou (in central and western Honan), and T'ao-ssu and Teng-hsia-feng (in southwest Shansi)—that stimulated the rise of early Bronze Age culture in the North China Plain and not in the east.

Lung-shan culture

Religious beliefs and social organization. The inhabitants of Neolithic China were, by the 5th millennium if not earlier, remarkably assiduous in the attention they paid to the disposition and commemoration of their dead. There was a consistency of orientation and posture, with the dead of the northwest given a westerly orientation and those of the east an easterly one. The dead were segregated, frequently in what appear to be kinship groupings (*e.g.*, at Yuan-chün-miao, Shensi). There were graveside ritual offerings of liquids, pig skulls, and pig jaws (*e.g.*, Pan-p'o and Ta-wen-k'ou), and the demanding practice of collective secondary burial, in which the bones of up to 70 or 80 corpses were stripped of their flesh and reburied together, was extensively practiced as early as the first half of the 5th millennium (*e.g.*, Yuan-chün-miao). Evidence of scapulimantic divination from the end of the 4th millennium (Fu-ho-kou-men, Liaoning) implies the existence of ritual specialists. There was a lavish expenditure of energy by the 3rd millennium on tomb ramps and coffin chambers (*e.g.*, Liu-wan [in eastern Tsinghai] and

Neolithic burial

Ta-wen-k'ou) and on the burial of redundant quantities of expensive grave goods (*e.g.,* Ta-fan-chuang in Shantung, Fu-ch'üan-shan in Shanghai, and Liu-wan), presumably for use by the dead in some afterlife.

Although there is no firm archaeological evidence of a shift from matriliny to patriliny, the goods buried in graves indicate during the course of the 4th and 3rd millennia an increase in general wealth, the gradual emergence of private or lineage property, increasing social differentiation and gender distinction of work roles, and a reduction in the relative wealth of women. The occasional practice of human sacrifice or accompanying-in-death from scattered 4th- and 3rd-millennium sites (*e.g.,* Miao-ti-kou I, Chang-ling-shan in Kiangsu, Ch'in-wei-chia in Kansu, and Liu-wan) suggests that ties of dependency and obligation were conceived as continuing beyond death and that women were likely to be in the dependent position. Early forms of ancestor worship, together with all that they imply for social organization and obligation among the living, were deeply rooted and extensively developed by the Late Neolithic Period. Such religious belief and practice undoubtedly served to validate and encourage the decline of the more egalitarian societies of earlier periods.

The first historical dynasty: the Shang

The advent of bronze casting. The 3rd and 2nd millennia witnessed the appearance of increasing warfare, complex urban settlements, intense status differentiation, and administrative and religious hierarchies that legitimated and controlled the massive mobilization of labour for dynastic work or warfare. The casting of bronze has left the most evident archaeological traces of these momentous changes, but its introduction must be seen as part of a far larger shift in the nature of society as a whole, representing an intensification of the social and religious practices of the Neolithic.

A Chalcolithic Age stretching back to the mid-5th millennium may be dimly perceived. A growing number of 3rd-millennium sites, primarily in the northwest but also in Honan and Shantung, have yielded primitive knives, awls, and drills made of copper and bronze. Stylistic evidence, such as the sharp angles, flat bottoms, and strap handles of certain Ch'i-chia clay pots (in Kansu; *c.* 2250–1900 BC), has led some scholars to posit an early sheet- or wrought-metal tradition possibly introduced from the west by migrating Indo-European peoples, but no wrought-metal objects have been found.

Use of copper and bronze

The construction and baking of the clay cores and sectional piece molds employed in Chinese bronze casting of the 2nd millennium indicate that early metalworking in China rapidly adapted to, if it did not develop indigenously from, the sophisticated, high-heat ceramic technology of the Late Neolithic potters, who were already using ceramic molds and cores to produce forms such as the hollow legs of the *li* caldron. Chinese bronze casting represents, as the continuity in vessel shapes suggests, an aesthetic and technological extension of that ceramic tradition rather than its replacement. The bronze casters' preference for vessels elevated on ring feet or legs further suggests aesthetic links to the east rather than the northwest.

The number, complexity, and size—the Ssu Mu Wu tetrapod weighed 1,925 pounds (875 kilograms)—of the Late Shang ritual vessels reveal high technological competence married to large-scale, labour-intensive metal production. Bronze casting of this scale and character—which placed large groups of ore miners, fuel gatherers, ceramists, and foundry workers under the prescriptive control of the model designers and labour coordinators—must be understood as a manifestation, both technological and social, of the high value that Shang culture placed upon hierarchy, social discipline, and central direction in all walks of life. The prestige of owning these metal objects must have derived in part from the political control over others that their production implied.

The Hsia dynasty

Chinese legends of the 1st millennium BC describe the labours of Yü, the Chinese "Noah" who drained away the floods to render China habitable and established the first Chinese dynasty, called Hsia. Seventeen Hsia kings are listed in the *Shih-chi,* a comprehensive history written during the 1st century BC, and much ingenuity has been devoted to identifying certain Late Neolithic fortified sites—such as Wang-ch'eng-kang ("the mound of the royal city") in north central Honan and Teng-hsia-feng in Hsia *hsien* (thus the site of Hsia-hsü, "the ruins of Hsia"?) in southern Shansi—as early Hsia capitals. T'ao-ssu, also in southern Shansi, has been identified as Hsia for the "royal" nature of five large male burials found there lavishly provided with grave goods. Although they fall within the region traditionally assigned to the Hsia, particular archaeological sites will be hard to identify dynastically unless written records are found. The possibility that Hsia and Shang were partly contemporary, as cultures if not as dynasties, further complicates site identifications. A related approach has been to identify as Hsia an archaeological horizon that lies developmentally between Late Neolithic and Shang strata.

The Shang dynasty. The first dynasty to leave historical records is thought to have ruled from the mid-16th to mid-11th century BC. (Some scholars date the Shang dynasty from the mid-18th to the late 12th century BC.) One must, however, distinguish Shang as an archaeological term from Shang as a dynastic one. Erh-li-t'ou in north central Honan, for example, was initially classified archaeologically as Early Shang; its developmental sequence from *c.* 2400 to 1450 BC documents the vessel types and burial customs that link Early Shang culture to the Late Neolithic cultures of the east. In dynastic terms, however, Erh-li-t'ou periods I and II (*c.* 1900 BC?) are now thought by many to represent a pre-Shang (and thus, perhaps, Hsia) horizon. In this view, the two palace foundations, the elite burials, the ceremonial jade blades and sceptres, the bronze axes and dagger axes, and the simple ritual bronzes—said to be the earliest yet found in China—of Erh-li-t'ou III (*c.* 1700–1600 BC?) signal the advent of the dynastic Shang.

Middle Shang sites

The archaeological classification of Middle Shang is represented by the remains found at Erh-li-kang (*c.* 1600 BC) near Cheng-chou, some 50 miles (80 kilometres) to the east of Erh-li-t'ou. The massive rammed-earth fortification, 118 feet (36 metres) wide at its base and enclosing an area of 1.2 square miles (3.2 square kilometres), would have taken 10,000 men more than 12 years to build. Also found were ritual bronzes, including four monumental tetrapods (the largest weighing 190 pounds; palace foundations; workshops for bronze casting, pot making, and bone working; burials; and two inscribed fragments of oracle bones. Another rammed-earth fortification, enclosing about 0.7 square mile and also dated to the Erh-li-kang period, has been found at Yen-shih, about three miles east of the Erh-li-t'ou III palace foundations. While these walls and palaces have been variously identified by modern scholars—the identification now favoured is of Cheng-chou as Po, the capital of the Shang dynasty during the reign of T'ang, the dynasty's founder—their dynastic affiliations are yet to be firmly established. The presence of two large, relatively close contemporary fortifications at Cheng-chou and Yen-shih, however, indicates the strategic importance of the area and impressive powers of labour mobilization.

P'an-lung-ch'eng in Hupeh, 280 miles south of Cheng-chou, is an example of Middle Shang expansion into the northwest, northeast, and south. A city wall, palace foundations, burials with human sacrifices, bronze workshops, and mortuary bronzes of the Erh-li-kang type form a complex that duplicates on a smaller scale Cheng-chou. A transitional period spanning the gap between the Upper Erh-li-kang phase of Middle Shang and the Yin-hsü phase of Late Shang indicates a widespread network of Shang cultural sites that were linked by uniform bronze-casting styles and mortuary practices. A relatively homogeneous culture united the Bronze Age elite through much of China around the 14th century BC.

Ruins of Yin

The Late Shang period is best represented by a cluster of sites focused on the village of Hsiao-t'un, west of An-yang in northern Honan. Known to history as Yin-hsü, "the Ruins of Yin" (Yin was the name used by the succeeding Chou dynasty for the Shang), it was a seat of royal power for the last nine Shang kings, from Wu-ting to Ti-hsin.

According to the "short chronology" used here, which is based upon modern studies of lunar eclipse records and reinterpretations of Chou annals, these kings would have reigned *c.* 1200–1045 BC. (One version of the traditional "long chronology," based primarily upon a 1st-century-BC source, would place the last 12 Shang kings, from P'an-keng onward, at Yin-hsü from 1398 to 1112 BC.) Sophisticated bronze, ceramic, stone, and bone industries were housed in a network of settlements surrounding the unwalled cult centre at Hsiao-t'un, which had rammed-earth temple-palace foundations. And Hsiao-t'un itself lay at the centre of a larger network of Late Shang sites—such as Hsing-t'ai to the north and Hsin-hsiang to the south—in southern Hopeh and northern Honan.

Royal burials. The royal cemetery lay less than two miles northwest of Hsiao-t'un, at Hsi-pei-kang. The hierarchy of burials at this and other cemeteries in the area reflected the social organization of the living. Large pit tombs, some nearly 42 feet deep, were furnished with four ramps and massive grave chambers for the kings. Retainers who accompanied their lords in death lay in or near the larger tombs; members of the lesser elite and commoners were buried in pits that ranged from medium size to shallow; those of still lower status were thrown into refuse pits and disused wells; and human and animal victims of the royal mortuary cult were placed in sacrificial pits. Only a few undisturbed elite burials have been unearthed, the most notable being that of Fu Hao, a consort of Wu-ting. That her relatively small grave contained 468 bronze objects, 775 jades, and more than 6,880 cowries suggests how great the wealth placed in the far larger royal tombs must have been.

The chariot. The light chariot, with 18 to 26 spokes per wheel, first appeared, according to the archaeological and inscriptional record, around 1200 BC. Glistening with bronze, it was initially a prestigious command car used primarily in hunting. The 16 chariot burials found at Hsiao-t'un raise the possibility of some form of Indo-European contact with China, and there is little doubt that the chariot, which probably originated in the Caucasus, entered China via Central Asia and the northern steppe. Animal-headed knives, always associated with chariot burials, are further evidence of a northern connection.

Art. Late Shang culture is also defined by the size, elaborate shapes, and evolved decor of the ritual bronzes, many of which were used in wine offerings to the ancestors and some of which were inscribed with ancestral dedications such as "Made for Father Ting." Their surfaces were ornamented with zoomorphic and theriomorphic elements set against intricate backgrounds of geometric meanders, spirals, and quills. Some of the animal forms—which include tigers, birds, snakes, dragons, cicadas, and water buffalo—have been thought to represent shamanistic familiars or emblems that ward away evil. The exact meaning of the iconography, however, may never be known. That the predominant *t'ao-t'ieh* monster mask—with bulging eyes, fangs, horns, and claws—may have been anticipated by designs carved on jade *ts'ung* tubes and axes from Liang-chu culture sites in the Yangtze Delta and from the Late Neolithic in Shantung suggests that its origins were ancient. But the degree to which pure form or intrinsic meaning took priority, in either Neolithic or Shang times, is hard to assess.

The *t'ao-t'ieh* mask

Late Shang divination and religion. Although certain complex symbols painted on Late Neolithic pots from Shantung suggest that primitive writing was emerging in the east in the 3rd millennium, the Shang divination inscriptions that appear at Hsiao-t'un form the earliest body of Chinese writing yet known. In Late Shang divination as practiced during the reign of Wu-ting (*c.* 1200–1180 BC), cattle scapulae or turtle plastrons, in a refinement of Neolithic practice, were first planed and bored with hollow depressions to which an intense heat source was then applied. The resulting T-shaped stress cracks were interpreted as lucky or unlucky. After the prognostication had been made, the day, the name of the presiding diviner (some 120 are known), the subject of the charge, the prognostication, and the result might be carved into the surface of the bone. Among the topics divined were sacrifices, campaigns, hunts, the good fortune of the 10-day week or of the night or day, weather, harvests, sickness, childbearing, dreams, settlement building, the issuing of orders, tribute, divine assistance, and prayers to various spirits. Some evolution in divinatory practice and theology evidently occurred. By the reigns of the last two Shang kings, Ti-i and Ti-hsin (*c.* 1100 to 1045 BC), the scope and form of Shang divination had become considerably simplified: prognostications were uniformly optimistic, and divination topics were limited mainly to the sacrificial schedule, the coming 10 days, the coming night, and hunting.

Early writing

State and society. The ritual schedule records 29 royal ancestors over a span of 17 generations who, from at least Wu-ting to Ti-hsin, were each known as *wang* (king). Presiding over a stable politico-religious hierarchy of ritual specialists, officers, artisans, retainers, and servile peasants, they ruled with varying degrees of intensity over the North China Plain and parts of Shantung, Shansi, and Shensi, mobilizing armies of at least several thousand men as the occasion arose.

The worship of royal ancestors was central to the maintenance of the dynasty. The ancestors were designated by 10 "stem" names (*chia, i, ping, ting,* etc.) that were often prefixed by kin titles, such as "father" and "grandfather," or by status appellations, such as "great" or "small." The same stems were used to name the 10 days (or suns) of the week, and ancestors received cult on their name days according to a fixed schedule, particularly after the reforms of Tsu-chia. For example, Ta-i ("Great I," the sacrificial name of T'ang, the dynasty founder) was worshiped on *i* days, Wu-ting on *ting* days. The Shang dynastic group, whose lineage name was Tsu (according to later sources), appears to have been divided into 10 units corresponding to the 10 stems. Succession to the kingship alternated on a generational basis between two major groupings of *chia* and *i* kings on the one hand and *ting* kings on the other. The attention paid in the sacrificial system to the consorts of "great lineage" kings—who were themselves both sons (possibly nephews) and fathers (possibly uncles) of kings—indicates that women may have played a key role in the marriage alliances that ensured such circulation of power.

The goodwill of the ancestors, and of certain river and mountain powers, was sought through prayer and offerings of grain, millet wine, and animal and human sacrifice. The highest power of all, with whom the ancestors mediated for the living king, was the relatively remote deity Ti, or Shang Ti, "the Lord on High." Ti controlled victory in battle, harvest, the fate of the capital, and the weather, but, on the evidence of the oracle bone inscriptions, he received no cult. This suggests that Ti's command was too inscrutable to be divined or influenced; he was, in all likelihood, an impartial figure of last theological resort, needed to account for inexplicable events.

The deity Ti

Although Marxist historians have categorized the Shang as a slave society, it would be more accurate to describe it as a dependent society. The king ruled a patrimonial state in which royal authority, treated as an extension of patriarchal control, was embedded in kinship and kinship-like ties. Despite the existence of such formal titles as "the many horse" or "the many archers," administration was apparently based primarily on kinship alliances, generational status, and personal charisma. The intensity with which ancestors were worshiped suggests the strength of the kinship system among the living; the ritualized ties of filiation and dependency that bound a son to his father, both before and after death, are likely to have had profound political implications for society as a whole. This was not a world in which concepts such as freedom and slavery would have been readily comprehensible. Everybody, from king to peasant, was bound by ties of obligation—to former kings, to ancestors, to superiors, and to dependents. The routine sacrificial offering of human beings, usually prisoners from the Ch'iang tribe, as if they were sacrificial animals, and the rarer practice of accompanying-in-death, in which 40 or more retainers, often of high status, were buried with a dead king, suggest the degree to which ties of affection, obligation, or servitude were thought to be stronger than life itself. If slavery existed, it was psychological and ideological, not legal. The

political ability to create and exploit ties of dependency originally based on kinship was one of the characteristic strengths of early Chinese civilization.

Such ties were fundamentally personal in nature. The king referred to himself as *yü i jen,* "I, the one man," and he was, like many early monarchs, peripatetic. Only by traveling through his domains could he ensure political and economic support. These considerations, coupled with the probability that the position of king circulated between social or ritual units, suggest that, lacking a national bureaucracy or effective means of control over distance, the dynasty was relatively weak. The Tzu should, above all, be regarded as a politically dominant lineage that may have displaced the Ssu lineage of the Hsia and that was in turn to be displaced by the Chi lineage of the Chou. But the choices that the Shang made—involving ancestor worship, the politico-religious nature of the state, patrimonial administration, the mantic role of the ruler, and a pervasive sense of social obligation—were not displaced. These choices endured and were to define, restrict, and enhance the institutions and political culture of the full-fledged dynasties yet to come. (D.N.K.)

The Chou and Ch'in dynasties

THE HISTORY OF THE CHOU (1111–255 BC)

The Chou ancestors

The origin of the Chou royal house is lost in the mists of time. Although the traditional historical system of the Chinese contains a Chou genealogy, no dates can be assigned to the ancestors. The first ancestor was Hou Chi, literally translated as "Lord of Millet." He appears to have been a cultural hero and agricultural deity rather than a tribal chief. The earliest plausible Chou ancestor was Tan Fu, the grandfather of Wen-wang. Prior to and during the time of Tan Fu, the Chou people seem to have migrated to avoid pressure from strong neighbours, possibly nomadic people to the north. Under the leadership of Tan Fu they settled in the valley of the Wei River in the present province of Shensi. The fertility of the loess soil there apparently made a great impression on these people, who had already been engaged in farming when they entered their new homeland. A walled city was built, and a new nation was formed. Archaeological remains, including ruins of courtyards surrounded by walls and halls on platforms, confirm literary evidence of a Chou state.

Chou and Shang. The name Chou appears often in the oracle bone inscriptions of the Shang kingdom, sometimes as a friendly tributary neighbour and at other times as a hostile one. This pattern is confirmed by records found at the Chou archaeological site. Marriages were occasionally made between the two ruling houses. The Chou also borrowed such arts as bronze casting from their more cultivated neighbour. The Chou royal house, however, had already conceived the idea of replacing Shang as the master of China—a conquest that took three generations. Although the conquest was actually carried out by his sons, Wen-wang should be credited with molding the Chou kingdom into the most formidable power west of the Shang. Wen-wang extended the Chou sphere of influence to the north of the Shang kingdom and also made incursions to the south, thus paving the way for the final conquest by Wu-wang.

Wen-wang and Wu-wang

In Chinese historical tradition Wen-wang was depicted as intelligent and benevolent, a man of virtue who won popularity among his contemporaries and expanded the realm of the Chou. His son, Wu-wang, though not as colourful as his father, was always regarded as the conqueror. In fact, Wu, his posthumous name, means "Martial." But the literary records indicate that the Chou actually controlled two-thirds of all China at the time of Wen-wang, who continued to recognize the cultural and political superiority of the Shang out of feudal loyalty. There is not enough evidence either to establish or to deny this. A careful historian, however, tends to take the Chou subjugation to the Shang as a recognition of Shang strength. It was not until the reign of the last Shang ruler, Chou, that the kingdom exhausted its strength by engaging in large-scale campaigning against nomads in the north and against a group of native tribes in the east. At this time Wu-wang organized the first probing expedition and reached the neighbourhood of the Shang capital. A full-scale invasion soon followed. Along with forces of the Chou, the army was made up of the Chiang, southern neighbours of the Chou, and of eight allied tribes from the west. The Shang dispatched a large army to meet the invaders. The pro-Chou records say that, after the Shang vanguard defected to join the Chou, the entire army collapsed, and Wu-wang entered the capital without resistance. Yet Mencius, the 4th-century-BC thinker, cast doubt upon the reliability of this account by pointing out that a victory without enemy resistance should not have been accompanied by the heavy casualties mentioned in the classical document. One may speculate that the Shang vanguard consisted of remnants of the eastern tribes suppressed by the Shang ruler Chou during his last expedition and that their sudden defection caught the Shang defenders by surprise, making them easy prey for the invading enemy. The decisive battle took place in 1111 BC (as tabulated by Tung Tso-pin, although it is commonly dated at 1122, and other dates have also been suggested). Wu-wang died shortly after the conquest, leaving a huge territory to be consolidated. This was accomplished by one of his brothers, Chou Kung, who served as regent during the reign of Wu's son, Ch'eng-wang.

The defeated Shang could not be ruled out as a potential force, even though their ruler, Chou, had immolated himself. Many groups of hostile "barbarians" were still outside the sphere of Chou power. The Chou leaders had to yield to reality by establishing a rather weak control over the conquered territory. The son of Chou was allowed to organize a subservient state under the close watch of two other brothers of Wu-wang, who were garrisoned in the immediate vicinity. Other leaders of the Chou and their allies were assigned lands surrounding the old Shang domain. But no sooner had Chou Kung assumed the role of regent than a large-scale rebellion broke out. His two brothers, entrusted with overseeing the activities of the son of Chou, joined the Shang prince, and it took Chou Kung three full years to reconquer the Shang domain, subjugate the eastern tribes, and reestablish the suzerainty of the Chou court.

These three years of extensive campaigning consolidated the rule of the Chou over all of China. An eastern capital was constructed on the middle reach of the Huang Ho (Yellow River) as a stronghold to support the feudal lords in the east. Several states established by Chou kinsmen and relatives were transferred further east and northeast as the vanguard of expansion, including one established by the son of Chou Kung. The total number of such feudal states mentioned in historical records and later accounts varies from 20 to 70; the figures in later records would naturally be higher, since enfeoffment might take place more than once. Each of these states included fortified cities. They were strung out along the valley of the Huang Ho between the old capital and the new eastern capital, reaching as far as the valleys of the Huai and Han rivers in the south and extending eastward to the Shantung Peninsula and the coastal area north of it. All these colonies mutually supported each other and were buttressed by the strength of the eastern capital, where the conquered Shang troops were kept, together with several divisions of the Chou legions. Ancient bronze inscriptions make frequent mention of mobilizing the military units at the eastern capital at times when the Chou feudal states needed assistance.

The Chou states

The Chou feudal system. The feudal states were not contiguous but, rather, were scattered at strategic locations surrounded by potentially dangerous and hostile nations. The fortified city of the feudal lord was often the only area that he controlled directly; the state and the city were therefore identical, both being *kuo,* a combination of city wall and weapons. Satellite cities were established at convenient distances from the main city in order to expand the territory under control. Each feudal state consisted of an alliance of the Chou, the Shang, and the local population. A Chinese nation was formed on the foundation of Chou feudalism.

The scattered feudal states gradually acquired something like territorial solidity as the neighbouring populations established closer ties with them, either by marriage or

by accepting vassal status; the gaps between the fortified cities were thus filled by political control and by cultural assimilation. This created a dilemma for the Chou central court: the evolution of the feudal network buttressed the structure of the Chou order, but the strong local ties and parochial interests of the feudal lords tended to pull them away from the centre. Each of these opposing forces became at one time or another strong enough to affect the history of the Chou order.

For about two centuries Chou China enjoyed stability and peace. There were wars against the non-Chou peoples of the interior and against the nomads along the northern frontier, but there was little dispute among the Chinese states themselves. The southern expansion was successful, and the northern expansion worked to keep the nomads away from the Chinese areas. The changing strength of the feudal order can be seen from two occurrences at the Chou court. In 841 BC the nobles jointly expelled Li-wang, a tyrant, and replaced him with a collective leadership headed by the two most influential nobles until the crown prince was enthroned. In 771 BC the Chou royal line was again broken when Yu-wang was killed by invading barbarians. The nobles apparently were split at this time, because two courts ensued, headed by two princes, each of whom had the support of part of the nobility. One of the pretenders, P'ing-wang, survived the other, but the royal order had lost prestige and influence. The cohesion of the feudal system had weakened. Thereafter, it entered a new phase traditionally known as the Ch'un-ch'iu ("Spring and Autumn") period (770–476 BC).

The Ch'un-ch'iu period

In the Ch'un-ch'iu period there was a gradual dilution of the familial relationship among the nobles. A characteristic of the Chou feudal system was that the extended family and the political structure were identical. The line of lordship was regarded as the line of elder brothers, who, therefore, enjoyed not only political superiority but also seniority in the family line. The head of the family not only was the political chief but also had the unique privilege of offering sacrifice to and worshiping the ancestors, who would bestow their blessings and guarantee the continuity of the mandate of Heaven. After the weakening of the position of the Chou king in the feudal structure, he was not able to maintain the position of being the head of a big family in any more than a normal sense. The feudal structure and familial ties fell apart, continuing in several of the Ch'un-ch'iu states for various lengths of time with various degrees of modification. Over the next two centuries the feudal-familial system gradually declined and disappeared.

Social ranks

In the first half of the Ch'un-ch'iu period the feudal system was a stratified society, divided into ranks as follows: the ruler of a state; the feudal lords who served at the ruler's court as ministers; the *shih* (roughly translated as "gentlemen") who served at the households of the feudal lords as stewards, sheriffs, or simply warriors; and, finally, the commoners and slaves. The state ruler and the ministers were clearly a superior class, and the commoners and slaves were an inferior class; the class of *shih* was an intermediate one in which the younger sons of the ministers, the sons of *shih,* and selected commoners all mingled to serve as functionaries and officials. The state rulers were, in theory, divided into five grades; in reality, the importance of a ruler was determined by the strength of his state. The ministerial feudal lords, however, often had two or three grades among themselves, as determined by the lord-vassal relationship. In general, each state was ruled by a group of hereditary feudal lords who might or might not be of the same surname as the state ruler. The system was not stable in the Ch'un-ch'iu period, and everywhere there were changes.

The first important change occurred with the advent of interstate leadership. For several decades after 722 BC the records show chiefly battles and diplomatic maneuvers among the states on the central plain and in the middle and lower reaches of the Huang Ho valley. These states, however, were too small to hold the leadership and too constricted in the already crowded plain to have potentiality for further development. The leadership was soon taken over by states on the peripheral areas.

The first to achieve this leadership was Huan Kung (reigned 685–643 BC), the ruler of the state of Ch'i on the Shantung Peninsula. He successfully rallied around him many other Chinese states to resist the pressure of non-Chinese powers in the north and south. While formally respecting the suzerainty of the Chou monarchy, Huan Kung adopted a new title of "overlord" (*pa*). He convened interstate meetings, settled disputes among states, and led campaigns to protect his followers from the intimidation of non-Chinese powers.

Rivalry among the Chou states

After his death the state of Ch'i failed to maintain its leading status. The leadership, after a number of years, passed to Wen Kung of Chin (reigned 636–628 BC), the ruler of the mountainous state north of the Huang Ho. Under Wen Kung and his capable successors, the overlordship was institutionalized until it took the place of the Chou monarchy. Interstate meetings were held at first during emergencies caused by challenges from the rising southern state of Ch'u. States answering the call of the overlord were expected to contribute and maintain a certain number of war chariots. Gradually the meetings became regular, and the voluntary contribution was transformed into a compulsory tribute to the court of the overlord. The new system of states under the leadership of an overlord developed not only in North China under Chin but also in the South under Ch'u. Two other states, Ch'in and Ch'i, while not commanding the strength of the formidable Chin and Ch'u, each absorbed weaker neighbours into a system of satellite states. A balance of power emerged among the four states of Ch'i, Ch'in, Chin, and Ch'u. The balance was occasionally tipped when two of them went to war, but it was subsequently restored by the transference of some small states from one camp to another.

Breakdown of the system

A further change began in the 5th century BC when the states of Wu and Yüeh far to the south suddenly challenged Ch'u for hegemony over the southern part of China, at a time when the strong state of Chin was much weakened by an internecine struggle among powerful magnates that subsequently split Chin into three contending powers. Wu got so far as to claim overlordship over North China in an interstate meeting held in 482 BC after defeating Ch'u. But Wu's hegemony was short-lived; it collapsed after being attacked by Yüeh. Although Yüeh held the nominal overlordship for a brief period, Chin, Ch'in, and Ch'i were weakened by internal disturbances and declined, and a series of defeats paralyzed Ch'u; thus the balance-of-power system was rendered unworkable.

A half century of disorder followed. Small states fell prey to big ones, while in the big states usurpers replaced the old rulers. When the chaos ended, there were seven major powers and half a dozen minor ones. Among the seven major powers, Chao, Han, and Wei had formerly been parts of Chin; the Ch'i ruling house had changed hands; and Ch'in was undergoing succession problems. The only "old" state was Ch'u. Even Ch'u, a southern state, had become almost completely assimilated to the northern culture (except in art, literature, and folklore). The minor powers had also changed: some had retained only small portions of their old territories, some had new ruling houses, and some were new states that had emerged from non-Chinese tribes. The long period of power struggle that followed is known as the Chan-kuo ("Warring States") period (475–221 BC).

SOCIAL, POLITICAL, AND CULTURAL CHANGES

The years from the 8th century BC to 221 BC witnessed the painful birth of a unified China. It was a period of bloody wars and also of far-reaching changes in politics, society, and intellectual outlook.

The decline of feudalism. The most obvious change in political institutions was the replacement of the old feudal structure by systems of incipient bureaucracy under monarchy. The decline of feudalism took its course in the Ch'un-ch'iu period, and the rise of the new order may be seen in the Chan-kuo period. The Chou feudalism suffered from a continual dilution of authority. As a state expanded, its nobility acquired vassals, and these in turn acquired their own vassals. The longer this went on, the more diluted became the family tie, and the more

dependent the ruler became on the combined strength of the vassals. At a certain point the vassals might acquire an advantageous position, and the most dominant figures among them might eclipse the king. The Chou royal house perhaps reached the turning point earlier than the other feudal states. The result was the shrinkage of the Chou royal domain and royal influence when P'ing-wang moved his court to the east. The ruling houses of other states suffered the same fate. Within a century after the Chou court moved to the east, the ruling houses in most of the feudal states had changed. Sometimes a dominating branch replaced the major lineage; sometimes a powerful minister formed a strong vassaldom and usurped the authority of the legitimate ruler. Bloody court intrigues and power struggles eliminated many established houses. The new power centres were reluctant to see the process continue and therefore refused to allow further segmentation and subinfeudation. Thus, the feudal system withered and finally collapsed.

Urbanization and assimilation. At the same time a process of urbanization was occurring. Minor fortified cities were built, radiating out from each of the major centres, and other towns radiated from the minor cities. From these cities and towns, orders were issued, and to them the resources of the countryside were sent. The central plain along the Huang Ho was the first to be saturated by clusters of cities. This is probably the reason why the central states soon reached the maximum of their influence in the interstate power struggle: unlike the states in peripheral areas, they had no room to expand.

Assimilation of non-Chou peoples

The period of urbanization was also a period of assimilation. The non-Chou population caught in the reach of feudal cities could not but feel the magnetic attraction of the civilization represented by the Chou people and Chou feudalism. The bronze inscriptions of the Hsi (Western) Chou (*c.* 1111–771 BC) refer to the disturbances of the "barbarians," who could be found practically everywhere. Those were the non-Chou groups scattered in the open spaces. The barbarians in inland China were forced to integrate with one or another of the contenders in the interstate conflicts. Their lands were annexed; their populations, moved or absorbed. The strength of the large states owed much to their success at incorporating these non-Chinese groups. By the time of the unification of China in the 3rd century BC, there was virtually no significant concentration of non-Chinese groups north of the Yangtze River valley and south of the steppe. Bronze pieces attributable to non-Chou chiefs in the late Ch'un-ch'iu period show no significant difference in writing system and style from those of the Chinese states.

Chou civilization was not assimilated so easily in the south, where the markedly different Ch'u culture flourished. For some centuries Ch'u was the archenemy of the Chinese states, yet the nobles of the Ch'u acquired enough of the northern culture to enable their envoy to the courts of the north to cite the same verses and observe the same manners. The Ch'u literature that has survived is the fruit of these two distinctive heritages.

To the north were the nomadic peoples of the steppe. As long as they remained divided, they constituted no threat, but under strong leaders, able to forge a nomadic empire challenging the dominance of the Chinese, there were confrontations. The "punitive" action into the north during the reign of Hsüan-wang (827–781 BC) does not seem to have been very large in scope; both sides apparently had little ambition for territorial aggrandizement. Cultural exchange in the northern frontier region was far less than the assimilation that occurred in the south along the Yangtze valley, and it was mainly concerned with techniques of cavalry warfare.

The rise of monarchy. As states grew in both population and area, there were internal political changes. The most basic change was in the pattern of the delegation of power. Under feudalism, authority had been delegated by the lord to the vassal. The new state rulers sought ways of maintaining and organizing their power.

In the state of Chin the influence of kinsmen of the ruling house had been trimmed even before Wen Kung established his overlordship. Wen Kung reorganized the government, installing his most capable followers in the key posts. He set up a hierarchical structure that corresponded to the channels of military command. Appointments to these key positions came to be based on a combination of merit and seniority, thus establishing a type of bureaucracy that was to become traditional in Chinese government.

Establishment of central controls

The Ch'u government was perhaps the oldest true monarchy among all the Ch'un-ch'iu states. The authority of the king was absolute. Ch'u was the only major state in which the ruling house survived the chaotic years of the Chan-kuo period.

Local administration went through a slow evolution. The prefecture system developed in both Chin and Ch'u was one innovation. In Chin there were several dozens of prefects across the state, having limited authority and limited tenure. The Chin prefect was no more than a functionary, in contrast to the feudal practice. In Ch'u similar local administrative units grew up. New lands taken by conquest were organized into prefectures governed by ranking officials who were evidently appointed by the king. The prefecture system of Chin and Ch'u was to become the principal form of local administration in the Chan-kuo period.

By that time practically all the major states had chancellors. A chancellor acted as the leader of the court, which was composed of numerous officials. Whereas in the feudal state the officials had been military officers, the more functionally differentiated court of the Chan-kuo period usually had a separate corps of civil service personnel. Local administration was entrusted to prefects, who served limited terms. Prefects were often required to submit annual reports to the court so that the ruler could judge their performance. Regional supervisors were sometimes dispatched to check the work of the prefects, a system developed by the later Chinese Imperial government into the "censor" system. Fiefs of substantial size were given to very few people, usually only to close relatives of the ruler. There was little opportunity for anyone to challenge the sovereignty of the state. The majority of government employees were not relatives of the ruler, and some of them might not even be citizens of the state. Officials were paid in grain or perhaps in a combination of cash and grain. Archives kept by scribes were on wooden blocks and bamboo strips. These features indicate the emergence of some form of bureaucracy.

The new pattern was the result of the efforts of many reformers in different states. Both practical men and theoreticians helped to form the new structure, which, though still crude, was the forerunner of the large and complex bureaucracy of later Chinese dynasties.

Military technique also underwent great changes in the Chan-kuo period. In the feudal era, war had been a profession of the nobles. Lengthy training was needed to learn the technique of driving and shooting from a chariot drawn by horses. There was also an elaborate code of behaviour in combat. The nature of war had changed by the late Ch'un-ch'iu period. The nobility had given way to professional warriors and mercenaries. In some states special titles of nobility were created for successful warriors, regardless of their origin. Foot soldiers were replacing war chariots as the main force on the battlefield. The expansion of the major states into mountainous areas and the rise of the southern powers in an area of swamps, lakes, and rivers increased the importance of the infantry.

New methods of warfare

Battles were fought mostly by hordes of foot soldiers, most of them commoners, aided by cavalry units; war chariots apparently served only auxiliary roles, probably as mobile commanding platforms or perhaps as carriers. All the Chan-kuo powers seem to have had conscription systems to recruit able-bodied male citizens. The organization, training, and command of the infantry required experts of a special type. The Chan-kuo period produced professional commanders who conducted battles involving several thousand men, with lines extending hundreds of miles. A few treatises on the principles of warfare still survive, including *Ping-fa* (*The Art of War*), by Sun-tzu. Cavalry warfare developed among the northern states, including Ch'in, Chao, and Yen. The Ch'in cavalrymen were generally drawn from the northern and northwest-

ern border areas, where there were constant contacts with the steppe peoples. The rise of Yen from a rather obscure state to a major power probably owed much to its successful adoption of cavalry tactics, as well as to its northern expansion.

Economic development. Important changes occurred in agriculture. Millet had once been the major cereal food in the north, but gradually wheat grew in importance. Rice, imported from the south, was extended to the dry soil of the north. The soybean in a number of varieties proved to be one of the most important crops. Chinese farmers gradually developed a kind of intensive agriculture. Soil was improved with the use of organic fertilizers. The fallow system was replaced by planting in carefully regulated rows. The importance of plowing and seeding at the proper time was stressed (especially in the fine-grained loess soil of North China). Frequent weeding was done throughout the growing season. Farmers also knew the value of rotating crops to preserve the fertility of the soil; soybeans were often part of the rotation. Although iron had been used to cast implements in the 5th century BC (probably even as early as the 8th century BC), those discovered by archaeologists are of rather inferior quality.

Agriculture

As population pressure forced the extension of cropland, irrigation became necessary. In the late Ch'un-ch'iu period and in the Chan-kuo period, irrigation works were constructed in many states. These projects were built to drain swampy areas, to leach out alkaline soil and replace it with fertile topsoil, and in the south and in the Szechwan Basin, to carry water into the rice paddies. The irrigation systems unearthed by modern archaeologists indicate that these were small-scale works carried out for the most part by state or local authorities.

Another significant change in the economic sphere was the growth of trade among regions. Coins excavated in scattered spots show, by their great variety, that active trade had been extended to all parts of Chou China. Great commercial centres had arisen, and the new cities brought a demand for luxuries. The literary records as well as the archaeological evidence show that wealthy persons had possessions made of bronze and gold, silver inlays, lacquer, silk, ceramics, and precious stones. The advancement of ferrous metallurgy led to the earliest recorded blast furnace and the earliest steel. The Chinese had been casting bronze for more than 1,000 years; turning to iron, they became very skillful at making weapons and tools. The Han historian Ssu-ma Ch'ien (writing about 100 BC) told of men making fortunes in the iron industry.

Trade

The Chan-kuo period witnessed the demise of the old feudal regimes and their replacement by centralized monarchies. The feudal nobility fell victim to power struggles within the states and to conquest by stronger states. During the Ch'un-ch'iu period these parallel processes drastically reduced the numbers of the nobility.

In the late Ch'un-ch'iu period there arose a new elite class, composed of the former *shih* class and the descendants of the old nobility. The members of this class were distinguished by being educated, either in the literary tradition or in the military arts. The *shih* provided the administrators, teachers, and intellectual leaders of the new society. The philosophers Confucius (551–479 BC), Mencius (*c.* 371–289 BC), Mo-tzu (5th century BC), and Hsün-tzu (*c.* 298–*c.* 230 BC) were members of the *shih* class, as were also a large proportion of high-ranking officials and leaders of prominence. The interstate competition that drove rulers to select the most capable and meritorious persons to serve in their courts resulted in an unprecedented degree of social mobility.

Emergence of a new intellectual elite

The populace, most of whom were farmers, also underwent changes in status. In feudal times the peasants had been subjects of their lords. They owned no property, being at most permitted to till a piece of the lord's land for their own needs. The ancient texts tell of the "well-field" system, under which eight families were assigned 100 *mou* (15 acres, or six hectares) each of land to live on while collectively cultivating another 100 *mou* as the lord's reservation. As farming became more intensive, there was a transition to individual ownership. This can be seen in the growth of the practice of taxing farmers according to the amount of land that they owned. By the time of the Chan-kuo period, the land tax had become a common practice. By paying taxes, the tiller of the field acquired the privilege of using the land as his own possession, which perhaps was the first step toward private ownership. As states expanded and as new lands were given to cultivation, an increasing number of "free" farmers were to be found tilling land that had never been part of a lord's manor. With the collapse of the feudal structure, farmers in general gradually ceased to be subjects of a master and became subjects of a state.

A similar transformation occurred among the merchants and craftsmen, who gradually passed from being household retainers of a lord to the status of independent subjects. Thus, the feudal society was completely reshaped in the two centuries preceding the Ch'in unification.

Cultural change. These great political and socioeconomic changes were accompanied by intellectual ferment, as the people tried to adjust themselves to a rapidly changing world. Ideas about the proper relationships between members of society were naturally questioned when the old feudal order was shaken; and, in this period, the great teacher Confucius elaborated the social concepts that were to become normative for later Chinese civilization. In place of rigid feudal obligations, he posited an order based on more universal human relationships (such as that between father and son) and taught that ability and moral excellence, rather than birth, were what fitted a man for leadership.

The great thinkers who followed Confucius, whether or not they agreed with his views, were conditioned by his basic assumptions. Mo-tzu, originally a Confucian, based his system on a concept of universal love that was largely an extension of the Confucian idea of humanity; the "worthy man" Mo-tzu recommended as the ideal leader was a development of Confucius' notion of excellence, combining virtue and ability. Even the individualist thinkers known as Taoists, who did not follow Confucius, formulated their teachings as a rebuttal to his system.

Confucius and other pre-Ch'in thinkers viewed the traditional political institutions of China as bankrupt and tried to devise a rationale for something to replace them. Some, such as Confucius, put their main emphasis on the quality of the ruling elite group; others, such as Shang Yang (died 338 BC) and Han-fei-tzu (died 233 BC), regarded a well-organized governing mechanism as the only way to an orderly society. The development of the new centralized monarchical state after the middle of the Ch'un-ch'iu period is not only the embodiment of the ideas of these various thinkers but also the working premise in the context of which they elaborated their theories. The high degree of social and political consciousness that characterized most of the pre-Ch'in philosophical schools set the pattern for the close association of the intellectual with government and society in later China.

The burgeoning commercial life of the period also had its influence in other spheres, especially in the prevalence of contractual relationships. Thus, a minister would roam from one court to another, "selling" his knowledge and service to the most accommodating prince, and the quality of his service was determined by the treatment he received. This kind of contractual relationship remained common in China until the tide of commercialism was ended by the restriction of commercial activity under the Han emperor Wu-ti in the 2nd century BC.

In the Ch'un-ch'iu period the local cultures of China were blended into one common civilization. Through contacts and interchanges, the gods and legends of one region became identified and assimilated with those of other regions. Local differences remained, but, from this time on, the general Chinese pantheon took the form of a congregation of gods with specific functions, a celestial projection of the unified Chinese empire with its bureaucratic society.

Bold challenges to tradition have been rare in Chinese history, and the questioning and innovating spirit of the Ch'un-ch'iu period was to have no parallel until the ferment of the 20th century, after two millennia had elapsed under the domination of Confucian orthodoxy.

THE CH'IN EMPIRE (221–206 BC)

The early Ch'in

The Ch'in state. The history of the Ch'in dynasty may be traced back to the 8th century BC. When the Chou royal house was reestablished at the eastern capital in 770 BC, the Ch'in ruling house, according to the Ch'in historical record, was entrusted with the mission of maintaining order in the previous capital. This may be an exaggeration of the importance of the Ch'in ruling house, and the Ch'in may have been only one of the ruling families of the old nations who recognized Chou suzerainty and went to serve the Chou court. The record is not clear. In the old annals Ch'in did not appear as a significant power until the time of Mu Kung (reigned 659–621 BC), who made Ch'in the main power in the western part of China. Although Ch'in attempted to obtain a foothold in the central heartland along the Huang Ho, it was blocked by the territories of Chin. After a number of failures to enter the eastern bloc of powers, Ch'in had to limit its activities to conquering, absorbing, and incorporating the non-Chinese tribes and states scattered within and west of the big loop of the Huang Ho. Ch'in's success in this was duly recognized by other powers of the Ch'un-ch'iu period, so that the two superpowers Ch'u and Chin had to grant Ch'in, along with Ch'i, the status of overlord in its own region. The eastern powers, however, regarded Ch'in as a "barbarian" state because of the non-Chinese elements it contained.

Ch'in played only a supporting role in the Ch'un-ch'iu power struggle; its location made it immune to the cutthroat competition of the states in the central plain. Ch'in, in fact, was the only major power that did not suffer battle within its own territory. Moreover, being a newly emerged state, Ch'in did not have the burden of a long-established feudal system; this allowed it more freedom to develop its own pattern of government. As a result of being "underdeveloped," it offered opportunity for eastern-educated persons; with the infusion of such talent, it was able to compete very well with the eastern powers, yet without the overexpanded ministerial apparatus that embarrassed other rulers. This may be one reason why Ch'in was one of the very few ruling houses that survived the great turmoil of the late Ch'un-ch'iu period.

A period of silence followed. Even the Ch'in historical record that was adopted by the historian Ssu-ma Ch'ien yields almost no information for a period of some 90 years in the 5th century BC. The evidence suggests that Ch'in underwent a period of consolidation and assimilation during the years of silence. When it reemerged as an important power, its culture appeared to be simpler and more martial, perhaps because of the non-Chinese tribes it had absorbed.

Struggle for power. Until the 5th century BC China was dominated by the central-plain power Wei, a successor to Chin, and by the eastern power Ch'i, a wealthy state with a new ruling house. Ch'in remained a secondary power until after the great reforms of Hsiao Kung (361–338 BC) and Shang Yang (Wei Yang).

Shang Yang's reforms

Shang Yang, a frustrated bureaucrat in the court of Wei, went westward seeking a chance to try out his ideas. In the court of Ch'in he established a rare partnership with the ruler Hsiao Kung in the creation of the best organized state of their time. Shang Yang first took strong measures to establish the authority of law and royal decree. The law was to be enforced impartially, without regard to status or position. He convinced Hsiao Kung that the rank of nobility and the privileges attached to it should be awarded only to those who rendered good service to the state, especially for valour in battle. This deprived the existing nobility of their titles and privileges, arousing much antagonism in the court.

One of his most influential reforms was the standardization of local administration. It was a step toward creating a unified state by combining various localities into counties, which were then organized into prefectures under direct supervision of the court. This system was expanded to all China after unification in 221 BC.

Another measure taken by Shang Yang was the encouragement of production, especially in agriculture. Farmers were given incentive to reclaim wasteland; game and fishing reserves were also opened to cultivation. A shortage of labour was met by recruiting able-bodied men from neighbouring states, especially from Han, Chao, and Wei. This policy of drawing workers to Ch'in had two consequences: an increase of production in Ch'in and a loss of manpower in the neighbouring states. In order to increase incentives, the Ch'in government levied a double tax on any male citizen who was not the master of a household. The result was a breakdown of the extended-family system, since younger children were forced to move out and establish their own households. The nuclear family became the prevalent form in Ch'in thereafter. As late as the 2nd century BC, Han scholars were still attacking the Ch'in family structure as failing to observe the principle of filial piety, a cardinal virtue in the Confucian moral code. Shang Yang also standardized the system of weights and measures, a reform of some importance for the development of trade and commerce.

Under the joint labours of Hsiao Kung and Shang Yang, Ch'in grew wealthy and powerful. After Hsiao Kung's death, Shang Yang was put to death by enemies at the Ch'in court. Tablets of the Ch'in law substantiate the survival of Shang Yang's policies after his death.

What remained of the Chou royal court still survived, ruling over a fragmentary domain: poor, weak, and totally at the mercy of the contending powers. It was commonly felt that China ought to be unified politically, although the powers disagreed as to how it was to be done and on who was to be the universal king. Hui-wang, son of Hsiao Kung, claimed the royal title in 325 BC. The adoption of the royal title by Ch'in, of course, was a challenge to Ch'i and Wei. Ch'in pursued a strategy of dividing its rivals and individually defeating them. Ch'in appealed to the self-interest of other powers in order to keep them from intervening in a military action it was taking against one of its neighbours. It befriended the more distant states while gradually absorbing the territories of those close to it.

Ch'in strategy

Within half a century, Ch'in had acquired undisputed predominance over the other contending powers. It continued maneuvering in order to prevent the others from uniting against it. A common topic of debate in the courts of the other states was whether to establish friendly relations with Ch'in or to join with other states in order to resist Ch'in's expansion. The Ch'in strategists were ruthless: all means, including lies, espionage, bribery, and assassination, were pressed into the service of their state.

For a time the eastern power Ch'i had seemed the most likely to win. It defeated Wei, crushed Yen in 314 BC, and annexed Sung in 286 BC. But Ch'i was overturned by an allied force of five states, including Ch'in. Chao, the power with extensive territory in the northern frontier, succeeded Ch'i as the most formidable contender against Ch'in. In 260 BC a decisive battle between Ch'in and Chao destroyed Chao's military strength, although Ch'in was not able to complete its conquest of Chao for several decades.

The empire. When Ch'in succeeded in unifying China in 221 BC, its king claimed the title of first sovereign emperor, Shih huang-ti. He was a strong and energetic ruler, and, although he appointed a number of capable aides, the emperor remained the final authority and the sole source of power.

Shih huang-ti made a number of important reforms. He abolished the feudal system completely and extended the administration system of prefectures and counties, with officials appointed by the central government sent into all of China. Circuit inspectors were dispatched to oversee the local magistrates. China was divided into some 40 prefectures. The empire of Shih huang-ti was to become the traditional territory of China. In later eras China sometimes held other territories, but the Ch'in boundaries were always considered to embrace the indivisible area of China proper. In order to control this vast area, Shih huang-ti constructed a network of highways for the movement of his troops. Several hundred thousand workers were conscripted to connect and strengthen the existing walls along the northern border. The result was a complex of fortified walls, garrison stations, and signal towers extending from the Po Hai (Gulf of Chihli) westward across the pastureland of what is today Inner Mongolia and through the fertile loop of the Huang Ho to the edge of Tibet.

The Great Wall

This defense line, known as the Great Wall, marked the frontier where the nomads of the great steppe and the Chinese farmers on the loess soil confronted each other. Yet the Emperor failed in another great project, the digging of a canal across the mountains in the south to link the southern coastal areas with the main body of China. Shih huang-ti, with his capable chancellor Li Ssu, also unified and simplified the writing system and codified the law.

All China felt the burden of these 11 or 12 years of change. Millions of men were dragooned to the huge construction jobs, many dying on the long journey to their destination. Rich and influential men in the provinces were compelled to move to the capital. Weapons were confiscated. Hundreds of intellectuals were massacred for daring to criticize the Emperor's policies. Books dealing with subjects other than law, horticulture, and herbal medicine were kept out of public circulation because the Emperor considered such knowledge to be dangerous and unsettling. These things have contributed to make Shih huang-ti appear the archtyrant of Chinese history.

Some of the accusations leveled against him by historians are perhaps exaggerated, such as the burning of books and the indiscriminate massacre of intellectuals. Shih huang-ti himself claimed in the stone inscriptions of his time that he had corrected the misconduct of a corrupted age and given the people peace and order. Indeed, his political philosophy did not deviate much from that already developed by the great thinkers of the Chan-kuo period and adopted later by the Han emperors, who have been generally regarded as benevolent rulers. Shih huang-ti was afraid of death. He did everything possible to achieve immortality. Deities were propitiated, and messengers were dispatched to look for an elixir of life. He died in 210/209 BC while on a tour of the empire. Excavation of his tomb, near modern Sian (ancient Ch'ang-an), revealed more than 6,000 life-sized statues of soldiers still on guard.

Fall of the Ch'in dynasty

His death led to the fall of his dynasty. The legitimate heir was compelled to commit suicide when his younger brother usurped the throne. Capable and loyal servants, including Li Ssu and Gen. Meng T'ien, were put to death. Ehr-shih ti, the second emperor, reigned only four years. Rebellion broke out in the Yangtze River area when a small group of conscripts led by a peasant killed their escort officers and claimed sovereignty for the former state of Ch'u. The uprising spread rapidly as old ruling elements of the six states rose to claim their former titles. Escaped conscripts and soldiers who had been hiding everywhere emerged in large numbers to attack the Imperial armies. The second emperor was killed by a powerful eunuch minister, and in 206 BC a rebel leader accepted the surrender of the last Ch'in prince. (C.-y.H.)

The Han dynasty

The Han dynasty was founded by Liu Pang (best known by his temple name, Kao-tsu), who assumed the title of emperor in 202 BC. Eleven members of the Liu family followed in his place as effective emperors until AD 9. In that year the dynastic line was challenged by Wang Mang, who established his own regime under the title of Hsin. In AD 25 the authority of the Han dynasty was reaffirmed by Liu Hsiu (posthumous name Kuang-wu ti), who reigned as Han emperor until 57/58. Thirteen of his descendants maintained the dynastic succession until 220, when the rule of a single empire was replaced by that of three separate kingdoms. While the whole period from 206 or 202 BC to AD 220 is generally described as that of the Han dynasty, the terms Hsi (Western; also called Former) Han and Tung (Eastern; also called Later) Han are used to denote the two subperiods. During the first period, from 206 BC to AD 25, the capital city was situated at Ch'ang-an, in the west; in the second period, from AD 25 to 220, it lay farther east at Lo-yang.

The four centuries in question may be treated as a single historical period by virtue of dynastic continuity; for, apart from the short interval of 9–25, Imperial authority was unquestionably vested in successive members of the same family. The period, however, was one of considerable changes in Imperial, political, and social development. Organs of government were established, tried, modified, or replaced, and new social distinctions were brought into being. Chinese prestige among other peoples varied with the political stability and military strength of the Han house, and the extent of territory that was subject to the jurisdiction of Han officials varied with the success of Han arms. At the same time the example of the palace, the activities of government, and the growing luxuries of city life gave rise to new standards of cultural and technological achievement.

Ch'in and Han dynasties compared

China's first Imperial dynasty, that of Ch'in, had lasted barely 15 years before its dissolution in the face of rebellion and civil war. By contrast, Han formed the first long-lasting regime that could successfully claim to be the sole authority entitled to wield administrative power. The Han forms of government, however, were derived in the first instance from the Ch'in dynasty; and these, in turn, incorporated a number of features of the government that had been practiced by earlier kingdoms. The Han Empire left as a heritage a practical example of Imperial government and an ideal of dynastic authority to which its successors have always aspired. But the Han period has been credited with more success than is its due; it has been represented as a period of 400 years of effective dynastic rule, punctuated by a short period of usurpation by a pretender to power, and it has been assumed that Imperial unity and effective administration advanced steadily with each decade. In fact, there were only a few short periods marked by dynastic strength, stable government, and intensive administration. Several reigns were characterized by palace intrigue and corrupt influences at court, and on a number of occasions the future of the dynasty was seriously endangered by outbreaks of violence, seizure of political power, or a crisis in the Imperial succession.

DYNASTIC AUTHORITY AND THE SUCCESSION OF EMPERORS

Hsi (Western) Han. Since at least as early as the Shang dynasty the Chinese had been accustomed to acknowledging the temporal and spiritual authority of a single leader and its transmission within a family, at first from brother to brother and later from father to son. Some of the early kings had been military commanders, and they may have organized the corporate work of the community, such as the manufacture of bronze tools and vessels. In addition, they acted as religious leaders, appointing scribes or priests to consult the oracles and thus to assist in making major decisions covering communal activities, such as warfare or hunting expeditions. In succeeding centuries the growing sophistication of Chinese culture was accompanied by demands for more intensive political organization and for more regular administration; as kings came to delegate tasks to more officials, so was their own authority enhanced and the obedience that they commanded the more widely acknowledged. Under the kingdoms of Chou an association was deliberately fostered between the authority of the king and the dispensation exercised over the universe by Heaven, with the result that the kings of Chou and, later, the emperors of Chinese dynasties were regarded as being the Sons of Heaven.

Events immediately preceding the foundation of the Han dynasty

From 403 BC onward seven kingdoms other than Chou constituted the ruling authorities in different parts of China, each of which was led by its own king or duke. In theory, the king of Chou, whose territory was by now greatly reduced, was recognized as possessing superior powers and moral overlordship over the other kingdoms, but practical administration lay in the hands of the seven kings and their professional advisers or in the hands of well-established families. Then in 221 BC, after a long process of expansion and takeover, a radical change occurred in Chinese politics: the kingdom of Ch'in succeeded in eliminating the power of its six rivals and established a single rule that was acknowledged in their territories. According to later Chinese historians, this success was achieved and the Ch'in Empire was thereafter maintained by oppressive methods and the rigorous enforcement of a harsh penal code, but this view was probably coloured by later political prejudices. Whatever the quality of Ch'in Imperial government, the regime scarcely survived the death of the first emperor (210/209 BC). The choice of

his successor was subject to manipulation by statesmen, and local rebellions soon developed into large-scale warfare. Kao-tsu, whose family had not so far figured in Chinese history, emerged as the victor of two principal contestants for power. Anxious to avoid the reputation of having replaced one oppressive regime by another, he and his advisers endeavoured to display their own empire—of Han—as a regime whose political principles were in keeping with a Chinese tradition of liberal and beneficent administration. As yet, however, the concept of a single centralized government that could command universal obedience was still subject to trial. In order to exercise and perpetuate its authority, therefore, Kao-tsu's government perforce adopted the organs of government, and possibly many of the methods, of its discredited predecessor.

The authority of the Han emperors had been won in the first instance by force of arms, and both Kao-tsu and his successors relied on the loyal cooperation of military leaders and on officials who organized the work of civil government. In theory and to a large extent in practice, the emperor remained the single source from whom all powers of government were delegated. It was the Han emperors who appointed men to the senior offices of the central government and in whose name the governors of the commanderies (provinces) collected taxes, recruited men for the labour corps and army, and dispensed justice. And it was the Han emperors who invested some of their kinsmen with powers to rule as kings over certain territories or divested them of such powers in order to consolidate the strength of the central government.

The Imperial succession

The succession of emperors was hereditary, but it was complicated to a considerable extent by a system of Imperial consorts and the implication of their families in politics. Of the large number of women who were housed in the palace as the emperor's favourites, one was selected for nomination as the empress; and while it was theoretically possible for an emperor to appoint any one of his sons heir apparent, this honour, in practice, usually fell on one of the sons of the empress. Changes could be made in the declared succession, however, by deposing one empress and giving the title to another favourite, and sometimes, when an emperor died without having nominated his heir, it was left to the senior statesmen of the day to arrange for a suitable successor. Whether or not an heir had been named, the succession was often open to question, as pressure could be exerted on an emperor over his choice. Sometimes a young or weak emperor was overawed by the expressed will of his mother or by anxiety to please a newly favoured concubine.

Throughout the Hsi Han and Tung Han periods, the succession and other important political considerations were affected by the members of the Imperial consorts' families. Often the father or brothers of an empress or concubine were appointed to high office in the central government; alternatively, senior statesmen might be able to curry favour with their emperor or consolidate their position at court by presenting a young female relative for the Imperial pleasure. In either situation the succession of emperors might be affected, jealousies would be aroused between the different families concerned, and the actual powers of a newly acceded emperor would be overshadowed by the women in his entourage or their male relatives. Such situations were particularly likely to develop if, as often happened, an emperor was succeeded by an infant son.

The Imperial succession was thus frequently bound up with the political machinations of statesmen, particularly as the court grew more sophisticated and statesmen acquired coteries of clients engaged in factional rivalry. On the death of the first emperor, Kao-tsu (195 BC), the palace came under the domination of his widow. Outliving her son, who had succeeded as emperor under the title of Hui-ti (reigned 195–188), the empress dowager Kao-hou arranged for two infants to succeed consecutively. During this time (188–180/179 BC) she issued Imperial edicts under her own name and by virtue of her own authority as empress dowager. She set a precedent that was to be followed in later dynastic crises—*e.g.,* when the throne was vacant and no heir had been appointed; in such cases, although statesmen or officials would in fact determine how to proceed, their decisions were implemented in the form of edicts promulgated by the senior surviving empress.

Kao-hou appointed a number of members of her own family to highly important positions of state and clearly hoped to substitute her own family for the reigning Liu family. But these plans were frustrated on her death (180/179) by men whose loyalties remained with the founding emperor and his family. Liu Heng, better known as Wen-ti, reigned from 180/179 to 157/156. He soon came to be regarded (with Kao-tsu and Wu-ti) as one of three outstanding emperors of the Hsi Han. He was credited with the ideal behaviour of a monarch reigning according to later Confucian doctrine; *i.e.,* he was supposedly ready to yield place to others, hearken to the advice and remonstrances of his statesmen, and eschew personal

extravagance. It can be claimed that his reign saw the peaceful consolidation of Imperial power, successful experimentation in operating the organs of government, and the steady growth of China's material resources.

Accomplishments of Wu-ti's reign

The third emperor of the Hsi Han to be singled out for special praise by traditional Chinese historians was Wu-ti (reigned 141/140–87/86 BC), whose reign was the longest of the whole Han period. His reputation as a vigorous and brave ruler derives from the long series of campaigns fought chiefly against the Hsiung-nu (northern nomads) and in Central Asia. But Wu-ti never took a personal part in the fighting. The policy of taking the offensive and extending Chinese influence into unknown territory resulted not from the Emperor's initiative but from the stimulus of a few statesmen, whose decisions were opposed vigorously at the time. Thanks to the same statesmen, Wu-ti's reign saw a more intensive use of manpower and exploitation of natural resources. This depended on more active administration by Han officials. Wu-ti participated personally in the religious cults of state far more actively than his predecessors and some of his successors. And it was during his reign that the state took new steps to promote scholarship and develop the civil service.

From *c.* 90 BC it became apparent that Han military strength had been overtaxed, and a policy of retrenchment was begun in military and economic policies. The last few years of the reign were darkened by a dynastic crisis arising out of jealousies between the Empress and heir apparent on the one hand, and a rival Imperial consort's family on the other. Intense and violent fighting took place in Ch'ang-an in 91, and the two families were almost eliminated. Just before Wu-ti's death a compromise was reached whereby an infant who came from neither family was chosen to succeed. This was Chao-ti (reigned 87/86–74/73). The stewardship of the empire was vested in the hands of a regent, Huo Kuang. This shrewd and circumspect statesman had seen service in government for some two decades, and even after his death his family retained a dominating influence in Chinese politics until 64 BC. Chao-ti had been married to a granddaughter of Huo Kuang; his successor, who was brought to the throne at the invitation of Huo Kuang and other statesmen, proved unfit for his august position and was deposed after a reign of 27 days. Huo Kuang, however, was able to contrive his replacement by a candidate whom he could control or manipulate. This was Hsüan-ti (reigned 74/73–48), who began to take a personal part in government after Huo Kuang's death in 68. The new emperor had a predilection for a practical rather than a scholastic approach to matters of state. While his reign was marked by a more rigorous attention to implementing the laws than had recently been fashionable, his edicts paid marked attention to the ideals of governing a people in their own interests and distributing bounties where they were most needed. The move away from the aggressive policies of Wu-ti's statesmen was even more noticeable during the next reign (Yüan-ti; 48–33/32).

The regency of Huo Kuang

In the reigns of Ch'eng-ti (33/32–7/6), Ai-ti (7/6–1 BC), and P'ing-ti (1 BC–AD 6) the conduct of state affairs and the atmosphere of the court were subject to the weakness or youth of the emperors, the lack of an heir to succeed Ch'eng-ti, and the rivalries between four families of Imperial consorts. It was a time when considerable attention was paid to omens. Changes that were first introduced in the state religious cults in 32 BC were alternately countermanded and reintroduced in the hope of securing material blessings by means of intercession with different spiritual powers. To satisfy the jealousies of a favourite, Ch'eng-ti went so far as to murder two sons born to him by other women. Ai-ti took steps to control the growing monopoly exercised by other families over state affairs. It was alleged at the time that the deaths of both Ch'eng-ti, who had enjoyed robust health, and P'ing-ti, not yet 14 when he died, had been arranged for political reasons.

In the meantime, the Wang family had come to dominate the court. Wang Cheng-chün, who had been the empress of Yüan-ti and mother of Ch'eng-ti, exercised considerable powers not only in her own capacity but also through several of her eight brothers. From 33/32 to 7/6 BC five members of the family were appointed in succession to the most powerful position in the government, and the status of other members was raised by the bestowal of nobilities. The Empress Dowager lived until AD 13, surviving the decline of the family's influence under Ai-ti, who sought to restore a balance at court by honouring the families of other consorts (the Fu and Ting families). Wang Mang, nephew of the empress dowager Wang, restored the family's position during the reign of P'ing-ti. After the latter died and an infant succeeded to the throne, Wang Mang was appointed regent, but in AD 9 he assumed the Imperial position himself, under the dynastic title of Hsin.

The regime of Wang Mang

Insofar as he took Imperial power from the Liu family, Wang Mang's short reign from 9 to 23 may be described as an act of usurpation. His policies were marked by both traditionalism and innovation. In creating new social distinctions, he tried to revert to a system allegedly in operation before the Imperial age, and some of his changes in the structure of government were similarly related to precedents of the dim past. He appealed to the poorer classes by instituting measures of relief, but his attempts to eliminate private landholding and abolish private slaveholding antagonized the more wealthy members of society. Experiments in new types of coinage and in controlling economic transactions failed to achieve their purpose of increasing the resources of state, which were depleted by enormously costly preparations for campaigns against the Hsiung-nu. The last years of his reign were dislocated by the rise of dissident bands in a number of provinces; several leaders declared themselves emperor in different regions, and in the course of the fighting Ch'ang-an was entered and damaged. Later it was captured by the Red Eyebrows, one of the most active of the robber bands; and Wang Mang was killed in a scene of violence played out within the palace buildings.

Tung (Eastern) Han. The Han house was restored by Liu Hsiu, better known as Kuang-wu ti, who reigned from AD 25 to 57/58. His claim had been contested by another member of the Liu house, Liu Hsüan—better known as Liu Keng-shih—who had been actually enthroned for two years, until his death in the course of turbulent civil fighting. Ch'ang-an had been virtually destroyed by warfare, and Kuang-wu ti established his capital at Lo-yang.

The new emperor completed the defeat of rival aspirants to the throne in 36. As had occurred in Hsi Han, dynastic establishment was followed by a period of internal consolidation rather than expansion. Kuang-wu ti resumed the structure of government of the Hsi Han emperors, together with the earlier coinage and system of taxation. The palace once more promoted the cause of scholarship. Eunuchs had come to the fore in the Han palace during Yüan-ti's reign, and several had succeeded in reaching powerful positions. Kuang-wu ti's policy was to rid the government of such influences, together with that of the families of Imperial consorts. Under Ming-ti (57/58–75/76) and Chang-ti (75/76–88), China was once more strong enough to adopt a positive foreign policy and to set Chinese armies on the march against the Hsiung-nu. To prevent the incursions of the latter, and possibly to encourage the growth of trade, Han influence was again brought to bear in Central Asia. Chinese prestige reached its zenith around 90 and fell markedly after 125.

Beginnings of Han decline

Dynastic decline can be dated from the reign of Ho-ti (88–105/106), when the court once more came under the influence of consorts' families and eunuchs. The succession of emperors became a matter of dexterous manipulation designed to preserve the advantages of interested parties. The weakness of the throne can be judged from the fact that, of the 12 emperors of Tung Han, no less than eight took the throne as boys aged between 100 days and 15 years. There was an increasing tendency for the growth of factions whose members, like the families of Imperial consorts and like the eunuchs, might choose to place their own interests above those of the state.

During the last 50 years of Tung Han, North China became subject to invasion from different sides; and, as was observed by several philosopher-statesmen, the administration became corrupt and ineffective. Powerful regional officials were able to establish themselves almost indepen-

dently of the central government. Rivalry between consorts' families and eunuchs led to a massacre of the latter in 189, and the rebel bands that arose included the Yellow Turbans, who were fired by beliefs in supernatural influences and led by inspired demagogues. Soldiers of fortune and contestants for power were putting troops in the field in their attempts to establish themselves as emperors of a single united China. By 207 Ts'ao Ts'ao had gained control over the north; and had he not been defeated by Sun Ch'üan at the battle of the Red Cliff, which later became famous in Chinese literature, he might well have succeeded in establishing a single dynastic rule. Other participants in the fighting included Tung Cho, Liu Pei, and Chu-ko Liang. The situation was resolved in 220 when Ts'ao P'ei, son of Ts'ao Ts'ao, accepted an instrument of abdication from Hsien-ti, last of the Han emperors (acceded 189). Ts'ao P'ei duly became emperor of a dynasty styled Wei, whose territories stretched over the northern part of China and whose capital was at Lo-yang. A year later, in 221, Liu Pei was declared emperor of the Shu-Han dynasty, thereby maintaining the fiction that as a member of the Liu family he was continuing its rule of the Han dynasty, albeit in the restricted regions of Shu in the southwest (capital at Ch'eng-tu). In the southeast there was formed the third of the San-kuo (Three Kingdoms), as the period from 220 to 280 has come to be described. This was the kingdom of Wu, with its capital at Chien-yeh, under the initial dispensation of Sun Ch'üan.

THE ADMINISTRATION OF THE HAN EMPIRE

The structure of government. One of the main contributions of the Han dynasty to the future of Imperial China lay in the development of the civil service and the structure of central and provincial government. The evolutionary changes that subsequently transformed Han polity beyond recognition were not directed at altering the underlying principles of government but at applying them expediently to the changing dynastic, political, social, and economic conditions of later centuries. One of the problems faced by Han governments was the recruitment of able and honest men to staff the civil service of an empire; these men eventually became known in the West as mandarins. Despite the recent reform of the script, which facilitated the drafting of documents, considerable training was still needed before sufficient competence could be attained. Much of the training occurred in local-level bureaus, where aspirants for Imperial appointments served the equivalent of apprenticeships. Meritorious young men advanced from clerical positions to head various local bureaus. Having proved themselves in these positions, they were then eligible for recommendation or sponsorship, the standard means of recruitment to the civil service. Officials were invited to present candidates who possessed suitable qualities of intelligence and integrity, usually established in their service in local bureaus, and at certain times provincial units were ordered to send a quota of men to the capital at regular intervals. At times candidates were required to submit answers on questions of policy or administration. They might then be kept at the palace to act as advisers in attendance, or they might be given appointments in the central government or in the provinces, depending upon their success. But at this time there was no regular system of examination and appointment such as was evolved in the time of the Sui and T'ang dynasties.

Recruitment of civil servants

The recruitment system was important for two reasons directly related to the nature and development of Han society. First, the apprenticeship system assured that entry into the Imperial bureaucracy was based on administrative merit. Thus, men of little wealth could enter clerical positions and support themselves while preparing for higher-level careers. (This recruitment system differed strikingly from the later examination system that often required years of study in which to master the Confucian Classics and to develop writing skills.) Second, powerful families, increasingly in the Tung Han period, were able to dominate the clerical and other positions in the local bureaus, thereby limiting to those powerful families the candidates for Imperial bureaucratic service. Control of local positions in turn strengthened the powerful families by allowing them to manipulate tax and census registers. Such families created the social milieu from which the aristocratic families of the post-Han period were to emerge.

There was a total of 12 grades in the Han civil service, ranging from that of clerk to the most senior minister of state. No division in principle existed between men serving in the central offices or the provincial units. Promotion could be achieved from one grade of the service to the next, and, in theory, a man could rise from the humblest to the highest post. In theory and partly in practice, the structure of Han government was marked by an adherence to regular hierarchies of authority, by the division of specialist responsibilities, and by a duplication of certain functions. By these means it was hoped that excessive monopoly of power by individual officials would be avoided. The uppermost stratum of officials or statesmen comprised the chancellor, the Imperial counselor, and, sometimes, the commander in chief. These men acted as the emperor's highest advisers and retained final control over the activities of government. Responsibility was shared with nine ministers of state who cared for matters such as religious cults, security of the palace, adjudication in criminal cases, diplomatic dealings with foreign leaders, and the collection and distribution of revenue. Each minister of state was supported by a department staffed by directors and subordinates. There were a few other major agencies; these ranked slightly below the nine ministries and were responsible for specialist tasks. Functions were duplicated so as to check the growth of power. Occasionally, for example, two chancellors were appointed concurrently. Similarly, financial matters were controlled by two permanent ministries: the Department of Agriculture and Revenue and the Privy Treasury.

The foregoing structure of regular organs of government was known as the Outer Court. With the passage of time it became balanced by the growth of a secondary seat of power known as the Inner Court. This grew up from members of the secretariat and had started as a subordinate agency in the Privy Treasury. The secretariat officials had acquired direct access to the emperor and could thus circumvent the more formal approaches required by protocol of other officials. The secretariat rose to prominence during the latter part of the 1st century BC and was at times staffed by eunuchs. Its members were sometimes distinguished by the bestowal of privileged titles that conveyed a mark of Imperial favour without specific administrative responsibility. The highest of these titles was that of supreme commander, and, when this title was accompanied by the right or the Imperial instruction to assume leadership of the secretariat, the powers of the incumbent outweighed those of the highest ministers of the Outer Court. An official thus named could effectively control decisions of state, to the discomfiture of senior officials such as the chancellor. It was in this capacity that Wang Mang and his four predecessors had been able to assert their power without fear of check.

Provincial government

At the outset of the Han dynasty very large areas were entrusted as kingdoms to the emperor's kinsmen while the central government administered the interior provinces as commanderies. But by *c.* 100 BC the Imperial government had deprived the kingdoms of their strength, and most of their lands had been incorporated as commanderies under the central government. Although the kingdoms survived in a much reduced form until the end of the period, their administration came to differ less and less from that of the commanderies, which formed the regular provincial units. Each commandery was controlled by two senior officials, the governor and the commandant, who were appointed by the central government. Commanderies could be established at will: by dividing larger into smaller units, by taking over the lands of the kings, or by establishing organs of government in regions only recently penetrated by Chinese officials. Provincial government was not necessarily pervasive throughout the lands where commandery offices existed, but there was a steady advance in provincial government during the Han period. During Kao-tsu's reign 16 commanderies existed, but by the end of the Hsi Han there were 83 commanderies and 20 kingdoms.

Each of the commanderies consisted of some 10 or 20

prefectures, the size of which corresponded to that of English counties. The prefect's headquarters were situated in a walled town, from which his administration was extended and his officials were sent to collect taxes, settle disputes, or recruit able-bodied men for service. The prefectures were themselves subdivided into districts. The commanderies included a number of nobilities, the holders of which enjoyed a noble title and income from the taxes collected in them by central government officials. The nobles exercised no administrative, judicial, or other power over their nobilities. The number of nobilities varied considerably, sometimes totaling several hundred. The system was used as a political instrument for reducing the power of the kings, rewarding military officers and civil officials, and treating surrendered enemy leaders. Special arrangements were instituted for provincial government at the periphery of the empire. Agencies of a specialist nature were set up both there and in the provinces of the interior, with responsibilities for such matters as supervision of the salt and iron industries, manufacture of textiles, fruit growing, and sponsored agriculture, as well as control of passage in and out of the frontier.

From 106 BC the government tried to supervise the work of provincial officials more directly. A total of 14 regional inspectors was appointed, with orders to visit the commanderies and kingdoms of a specified area and to report to the central government on the efficiency of officials, the degree of oppression or corruption, and the state of popular affection or disaffection. Although the arrangement was not yet tantamount to the creation of a limited number (about 20) of large provinces, such as came about from about the 13th century, it may have facilitated the establishment of separatist provincial regimes at times of dynastic decline.

Command of the armed forces

The command of the armed forces was also arranged so as to avoid giving excessive powers to a single individual. General officers were usually appointed in pairs, and, in times of emergency or when a campaign was being planned with a defined objective, officers were appointed for a specific task; when their mission was fulfilled, their commands were brought to a close. At a lower level there existed a complement of colonels whose duties were defined so as to cover smaller scale activities. In addition, the governors and commandants of the commanderies were sometimes ordered to lead forces. The commandants were also responsible for training conscript soldiers and setting them to maintain internal discipline and to man the static lines of defense in the north and northwest.

The Han armies drew their recruits from conscripts, volunteers, and convicts. Conscripts, who formed the majority, were obliged to serve for two years, either under training or on active service. This duty devolved on all able-bodied males other than those who had acquired privileges of rank or those who could pay for substitutes. The latter practice was probably rare. In addition, men were liable for recall to the armed forces in times of emergency. Volunteers were the sons of privileged families and probably served as cavalrymen, and convicts were sometimes drafted to work out their terms of sentence in the army. There is ample evidence to show that Han commanders used to draw on Central Asian tribesmen as recruits, and the tribesmen were particularly valuable as skilled cavalrymen. A number of foreigners also served with distinction as officers. While little is known of the organization of armies on campaign, garrison forces were divided into separate commands consisting of perhaps four companies. Each company had a strength of some 40 or 50 sections, each of which comprised one officer and up to five men.

The practice of government. As the final arbiter of power, the emperor—and at times the empress dowager—issued edicts declaring the Imperial will. Such instructions often took the form of repeating officials' proposals with a note of approval. Some edicts were couched as comments on the current situation and called in general terms for an improvement in the quality of government or for more vigorous attempts to achieve a just administration. The emperor also issued formal deeds of investiture to kings or noblemen and letters of appointment for senior officials. Edicts were circulated to the relevant authorities for action, together with books of other regulations such as the statutes and ordinances, laying down entitlements for services rendered to the state and penalties for infringing its prohibitions. Officials could suggest methods of government by submitting written memorials, and there were occasions when an emperor called a conference of senior statesmen and asked their views on topical problems.

The Han governments regularly issued calendars to enable the court to follow a cosmically correct ritual schedule and officials to maintain their records correctly. Regular means of transport were kept for the use of officials traveling on business and for the conveyance of official mail from one office to another. Provincial and local officials were responsible for two regular counts without which government could not proceed: the census of the population and the register of the land and its production. Returns, which were submitted for the number of households and individuals and for acreage under the plow, eventually found their way to the capital. One count that has been preserved records the existence of some 12,233,000 households and 59,595,000 individuals in AD 2. Two other main forms of revenue collection were the land tax and the poll tax. The land tax was levied in kind at a 30th (sometimes a 15th) part of the produce, the assessment depending partly on the quality of the land. Poll tax was usually paid in cash and varied with the age and sex of the members of the household. Other taxes were levied in respect to wealth and by means of property assessments.

Use of the census

In addition to service in the army, able-bodied males were liable to one month's service annually in the state labour corps; tasks included building palaces and Imperial mausoleums, transporting staple goods such as grain and hemp, and constructing roads and bridges. Sometimes conscript labour was used to repair breaches in riverbanks or dikes, and men were sent to work in the salt and iron industries after these were taken over by the state.

State monopolies

The establishment of state monopolies for salt and iron was one of several measures taken in Wu-ti's reign to bring China's resources under the control of the government. Agencies were set up *c.* 117 BC to supervise mining, manufacturing, and distribution and to raise revenue in the process. The measure was criticized on the grounds both of principle and of expedient and was withdrawn for three years from 44 BC, and by the mid-1st century AD the industries had reverted in practice to private hands. Final measures to standardize the coinage and to limit minting to state agencies were taken in 112 BC; and, with the exception of Wang Mang's experiments, the copper coin of a single denomination, minted from Wu-ti's reign onward, remained the standard medium of exchange. Little is known of the work of other agencies established in Hsi Han to stabilize the prices of staple commodities and to regulate their transport. Such measures had been the answer of Wu-ti's government to the problem of moving goods from an area of surplus to one of shortage.

The government ordered migrations of the population for several reasons. At times, such a migration was intended to populate an area artificially—the city of Hsienyang during the Ch'in Empire, for example, and the state-sponsored farms of the borderlands. Alternatively, if the defense of the periphery was impractical, the population was sometimes moved away from danger, and distressed folk were moved to areas where they could find a more prosperous way of life.

From about 100 BC it was evident to some statesmen that great disparities of wealth existed and that this was most noticeable in respect of landownership. Some philosophers looked back nostalgically to an ideal state in which land was said to have been allotted and held on a basis of equality, thereby eliminating the wide differences between rich and poor. It was only in Wang Mang's time that an attempt was made to abolish private landownership and private slaveholding. But the attempt failed because of powerful economic and social opposition, and the accumulation of land continued during Tung Han. In the last half century or so of the dynasty, country estates acquired retainers and armed defenders, almost independently of the writ of government. The great families thus came to exercise more power than appointed officials of state.

Han law

The Han, like the Ch'in, government ruled by dispensing rewards for service and exacting punishment for disobedience and crime. Rewards consisted of exemptions from tax; bounties of gold, meat, spirits, or silk; amnesties for criminals; and orders of honour. The latter were bestowed either individually or to groups. There was a scale of rank of 20 degrees, and, with the receipt of several of these awards cumulatively, one could rise to the eighth place in the scale. The more senior orders were given for specified acts of valour, charity, or good administration, usually to officials, and the highest of the orders was that of the nobility. In addition to conferring social status, the orders carried with them legal privileges and freedom from some tax and service obligations.

In theory, the laws of Han were binding on all members of the population, and some incidents testify to the punishment of the highest in the land. But some privileged persons were able to secure mitigation of sentences. Nobles, for example, could ransom themselves from most punishments by forfeiting their nobilities. Han laws specified a variety of crimes, including those of a social nature such as murder or theft, those that infringed the Imperial majesty, and offenses that were classed as gross immorality. There was a regular procedure for impeachment and trial, and some difficult cases could be referred to the emperor for a final decision. The punishments to which criminals were sentenced included exile, hard labour, flogging, castration, and death. In the most heinous cases the death sentence was carried out publicly, but senior officials and members of the Imperial family were usually allowed to avoid such a scene by committing suicide. After the death penalty a criminal's goods, including members of his family, were confiscated by the state. Such persons then became slaves of the state and were employed on menial or domestic tasks in government offices. Government slaves were sometimes given as rewards to meritorious officials.

RELATIONS WITH OTHER PEOPLES

Simultaneously with the rise of the Ch'in and Han empires, some of the nomadic peoples of Central Asia, known as the Hsiung-nu, succeeded in achieving a measure of unity under a single leader. As a result, while the Chinese were consolidating their government, the lands lying to the north of the empire, and the northern provinces themselves, became subject to incursion by Hsiung-nu horsemen. One of the achievements of the Ch'in dynasty had been the unification of the several lines of defense into a single system of fortification, the Great Wall. By keeping that wall, or line of earthworks, manned, the Ch'in dynasty had been free of invasion. With the fall of Ch'in and China's subsequent weakness, the wall fell into a state of disrepair and lacked a garrison. Until about 135 BC Han governments were obliged to seek peaceful relations with the Hsiung-nu at the price of gold, silk, and even the hand of a Chinese princess. But with the initiation of strong policies by Wu-ti's governments, China took the offensive in an attempt to throw back the Hsiung-nu to Central Asia and to free the northern provinces from the threat of invasion and violence. By 119 BC campaigns fought to the north of Chinese territory had attained this objective, and after a short interval it was possible to send Han armies to advance in the northeast (modern Korea), the south (modern Vietnam), and the southwest. As a result of the campaigns fought from 135 BC onward, 18 additional commanderies were founded, and organs of Han provincial government were installed as outposts among peoples who were unassimilated to a Chinese way of life.

Relations with the Hsiung-nu

Chinese government was by no means universally accepted in these outlying regions. But despite large losses and expenditures incurred in fighting the Hsiung-nu, the Chinese were able to mount expeditions into Central Asia from *c.* 112 BC. The defensive walls were repaired and remanned, and by *c.* 100 BC they were extended to the northwest as far as Tun-huang. Chinese travelers, whether diplomats or merchants, were thus protected as far as the Takla Makan Desert. It was at this juncture that trade routes skirting the desert were established and came to be known collectively as the Silk Road.

The success of Chinese arms in these remote areas was short-lived. Long lines of communication made it impossible to set up garrisons or colonies in the forbidding country to the west of Tun-huang. Diplomatic moves were made to implant Chinese prestige more firmly among the communities that were situated around the Takla Makan Desert and controlled the oases, for it was necessary for the Chinese to win those peoples' support, thus denying it to the Hsiung-nu. In a few cases the Chinese resorted to violence or plots to remove a leader and to replace him with a candidate known to favour the Han cause. A more usual procedure was to marry one of the alien leaders to a Chinese princess, with the intention that he should in time be succeeded by an heir who was half-Chinese. These endeavours and the military ventures met with partial success. While the Chinese position in Central Asia was subject to question, relations with the Hsiung-nu leaders varied. The visit of a Hsiung-nu leader to Ch'ang-an in 51 BC was hailed as a mark of Chinese success, but the ensuing decades were not free from fighting. Chinese prestige declined toward the end of the Hsi Han and recovered only during the reigns of Ming-ti and Chang-ti, when the Han government was once more strong enough to take the field. Pan Ch'ao's campaigns in Central Asia (from AD 94) reestablished the Chinese position, but again the full strength of Chinese prestige lasted for only a few decades. During the Tung Han, China suffered invasion from the northeast as well as from the north. The settlement of Hsiung-nu tribesmen south of the wall was a disruptive factor in the 2nd and 3rd centuries, to the detriment of Imperial unity.

The Han expansion into Central Asia has been represented by the Chinese as a defensive measure designed to weaken the Hsiung-nu and to free China from invasion. Allowance must also be made for commercial motives. Some of Wu-ti's statesmen were well aware of the advantages of exporting China's surplus products in return for animals and animal products from Central Asia, and there is evidence that Chinese silk was exported at this time. No attempt can be made to estimate the volume of trade, and, as the transactions were conducted through Parthian middlemen, no direct contact was made by this means between Han China and the world of Rome and the Mediterranean. China's export trade was sponsored by the government and not entrusted to private merchants.

External trade

The Great Wall formed a boundary separating the Chinese provinces from the outside world. Traffic was controlled at points of access, not only to check incoming travelers to China but also to prevent the escape of criminals or deserters. At the same time, a ban was imposed on the export of certain goods such as iron manufactures and weapons of war. The wall also formed a protected causeway for travelers to the west. Watch stations were erected in sight of each other to signal the approach of the enemy, and the garrison troops were highly trained and disciplined. Meticulous records were kept to show how government stores were expended and rations issued; routine signals were relayed along the line and daily patrols were sent out to reconnoitre.

As a result of the campaigns and of diplomatic activity, China's immediate contacts with other peoples grew more brisk. Many of the Hsiung-nu and other neighbouring leaders who had surrendered to Han arms were given nobilities and settled in the interior of the empire. Chang Ch'ien had been the pioneer who had set out *c.* 130 BC to explore the routes into Central Asia and North China, and, as a result of his report and observations, Han advances were concentrated in the northwest. In AD 97 Chinese envoys were frustrated in an attempt to visit the western part of the world, but a mission from Rome reached China by ship in 166. The first record of official visitors arriving at the Han court from Japan is for the year AD 57.

CULTURAL DEVELOPMENTS

The Han emperors and governments posed as having a temporal dispensation that had received the blessing of Heaven together with its instructions to spread the benefits of a cultured life as widely as possible. By a cultured life the Chinese had in mind a clear distinction between their own settled agriculture and the delights of the cities, as

opposed to the rough and hardy life spent in the saddle by the nomads of Central Asia. The growth of Han government both depended upon and encouraged the development of literary accomplishment, scholastic competence, religious activity, scientific discovery, and technological achievement.

The discovery of paper

Han administration required a proliferation of documents. Official returns were sometimes kept in duplicate, and each agency kept running files to record its business. Following the reform of the script that had evolved before the Han period, there developed a new style of writing suited to the compilation of official documents. These were written mostly on bulky and fragile wooden strips; silk was also used as a medium for writing. A major development in world history occurred in China in AD 105 when officials reported to the throne the manufacture of a new substance. Although archaeological evidence indicates the existence of paper for more than a century before this incident, the earlier materials were not completely superseded until some three or four centuries later. In the meantime, the demands of a growing civilization had increased the written vocabulary of the Chinese. The first Chinese dictionary, compiled *c.* AD 100, included more than 9,000 characters, with explanations of their meanings and the variant forms used in writing.

In an attempt to break with earlier tradition, the Ch'in government had taken certain steps to proscribe literature and learning. Han governments stressed their desire to promote these causes as part of their mission. In particular, they displayed a veneration for works with which Confucius had been associated, either as a collector of texts or as an editor. Beginning during the reign of Wen-ti, orders were given to search for books lost during the previous dynasty. Knowledge of texts such as the *Shih Ching* ("Classic of Poetry"), the *Shu Ching* ("Classic of History"), the *I Ching* ("Classic of Changes"), and the *Ch'un-ch'iu* ("Spring and Autumn") annals became a necessary accomplishment for officials and candidates for the civil service. To support an argument laid before the throne, statesmen would find a relevant quotation from these works; already in the 1st century BC the tradition was being formed whereby the civil service of Imperial China was nurtured on a Classical education. On two occasions (51 BC and AD 79) the government ordered official discussions about the interpretation of texts and the validity of differing versions; and in AD 175 a project was completed for inscribing an approved version on stone tablets, so as to allay scholastic doubts in the future. In the meantime, and still before the invention of paper, a collection of literary texts had been made for the Imperial library. The catalog of this collection, which dates from the start of the Christian Era, was prepared after comparing different copies and eliminating duplicates. The list of titles has been preserved and constitutes China's first bibliographical list. The works are classified according to subject, but many have been lost. The importance of these measures lies both in their intrinsic achievement and in the example they set for subsequent dynasties.

Rise of Classical education

The prose style of Han writers was later taken as a model of simplicity, and, following the literary embellishments and artificialities of the 5th and 6th centuries, deliberate attempts were made to revert to its natural elegance. Examples of this direct prose may be seen in the Imperial edicts, in the memorials ascribed to statesmen, and, above all, in the text of the standard histories themselves, in which such documents of state were incorporated. The compilation of the standard histories was a private undertaking in Han times, but it already received Imperial patronage and assistance. History was written partly to justify the authority and conduct of the contemporary regime and partly as a matter of pride in Chinese achievement. Further examples of prose writing are the descriptions of protocol for the court. One of the earliest acts of the Han government (*c.* 200 BC) had been to order the formulation of such modes of behaviour as a means of enhancing the dignity of the throne, and one of the latest compilations (*c.* AD 175) that still survives is a list of such prescriptions, drawn up at a time when the dynasty was manifestly losing its majesty and natural authority. Some of the emperors were themselves composers of versified prose; their efforts have also been preserved in the standard histories.

Religious practices

The emperor was charged with the solemn duty of securing the blessings of spiritual powers for mankind. One of the nine ministries of state existed to assist in this work of mediation, but from the time of Wu-ti onward the emperor himself began to play a more active part in worship and sacrifice. The cults were initially addressed to the Five Elements—fire, water, earth, wood, and metal; to the Supreme Unity; and to the Lord of the Soil. In 31 BC these cults were replaced by sacrifices dedicated to Heaven and Earth. The sites of worship were transferred to the southern and northern outskirts of Ch'ang-an, and a new series of altars and shrines was inaugurated. On occasion the Han emperor paid his respects to supreme powers and reported on the state of the dynasty at the summit of Mt. T'ai. Wu-ti's desire for immortality or for the quickening of his deceased favourites led him to patronize a number of intermediaries who claimed to possess the secret of making contact with the world of the immortals. From such beliefs, and from a fear of the malevolent influences that the unappeased souls of the dead could wreak on mankind, a few philosophers, such as Wang Ch'ung (AD 27–*c.* 100), reacted by propounding an ordered and rational explanation of the universe. But their skepticism received little support. Sometime during the 1st century AD Buddhism had reached China, propagated in all probability by travelers who had taken the Silk Road from north India. The establishment of Buddhist foundations in China and the first official patronage of the faith followed shortly. From the 2nd century AD there arose a variety of beliefs, practices, and disciplines from which alchemy and scientific experiment were to spring and which were to give rise to Taoist religion.

Most of the cultural attainments of the Han period derived from the encouragement of the palace and the needs of officials. A textbook of mathematical problems was probably compiled to assist officials in work such as land assessment; fragments of a medical casebook were concerned with the care of troops and horses serving on the northwestern frontier. Water clocks and sundials were used to enable officials to complete their work on schedule. The palace demanded the services of artists and craftsmen to decorate Imperial buildings with paintings and sculptures and to design and execute jades, gold and silver wares, and lacquer bowls for use at the Imperial table. Intricate patterns in multicoloured silks were woven on looms in the Imperial workshops. On a more mundane level, technology served the cause of practical government. The state's ironwork factories produced precision-made instruments and weapons of war, and the state's agencies for the salt industry supervised the recovery of brine from deep shafts cut in the rocks of west China. Water engineers planned the construction of dikes to divert the flow of excess waters and the excavation of canals to serve the needs of transport or irrigation; and in many parts of the countryside there was seen a sight that was to remain typical of the Chinese landscape up to the 20th century—a team of two or three peasants sitting astride a beam and pedaling the lugs of the "dragon's backbone" so as to lever water from the sluggish channels below to the upper levels of the cultivated land. (J.L.D./Ed.)

The Six Dynasties

POLITICAL DEVELOPMENTS

The division of China. *San-kuo (Three Kingdoms; AD 220–280).* By the end of the 2nd century AD the Han Empire had virtually ceased to exist. The repression of the Taoist rebellions of the Yellow Turbans and related sects marked the beginning of a period of unbridled warlordism and political chaos, from which three independent centres of political power emerged. In the north all authority had passed into the hands of the generalissimo and "protector of the dynasty," Ts'ao Ts'ao; in AD 220 the last puppet emperor of the Han officially ceded the throne to Ts'ao Ts'ao's son, who thereby became the legitimate heir of the empire and the first ruler of the Wei dynasty. Soon afterward, two competing military leaders proclaimed them-

The Wei, Shu-Han, and Wu dynasties

selves emperor, one in the far interior (Shu-Han dynasty, in the present-day Szechwan Province) and one in the south, behind the formidable barrier of the Yangtze River (the empire of Wu, with its capital at Chien-yeh, present-day Nanking). The short and turbulent period of these "Three Kingdoms" (San-kuo), filled with bloody warfare and diplomatic intrigue, has ever since been glorified in Chinese historical fiction as an age of chivalry and individual heroism.

In fact, even Wei, the strongest of the three, hardly represented any real political power. The great socioeconomic changes that had started in the Tung (Eastern) Han period had transformed the structure of society to such an extent that all attempts to reestablish the centralized bureaucratic state—the ideal of the Ch'in and Han dynasties—were doomed to failure. While central authority declined, the great families—aristocratic clans of great landowners—survived the decades of civil war on their fortified estates under the protection of their private armies of serfs and clients and even increased their power. These conditions were to remain characteristic of medieval China. The Han system of recruiting officials on the basis of talent was replaced by a network of personal relations and patronage. The hierarchy of state officials and government institutions was never abolished, but it became monopolized by a few aristocratic clans, who filled the highest offices with their own members and the minor posts with their clients.

Wei succeeded in conquering Shu-Han in 263/264, but two years later a general of the dominant Ssu-ma clan overthrew the house of Wei (265/266) and founded the Hsi (Western) Chin dynasty (265). Wu could maintain itself until 280, when it was overrun by the Chin armies.

The role of Wu was extremely important: it marks the beginning of the progressive Sinicization of the region south of the Yangtze River, which before that time had been a frontier area, inhabited mainly by primitive tribes. The rise of Chien-k'ang (modern Nanking) as a great administrative and cultural centre on the lower Yangtze paved the way for future developments: after the north was lost to barbarian invaders (311), it was to become the capital of Chinese successor states and an important locus of Chinese culture for more than 250 years.

The Hsi (Western) Chin (AD 265–316/317). This was a period of relative order and prosperity, a short interlude between the turbulent age of the San-kuo and the devastating barbarian invasions. The empire had been nominally reunited (AD 280), and for a short time the central government attempted important fiscal and political reforms, mainly intended to curb the great families, which threatened the ruler's authority. Contacts with the oasis kingdoms of Central Asia and the Indianized states of the far south (Funan and Champa) were resumed, and in 285

China in the Six Dynasties period.

the Chin court even sent an envoy to distant Fergana in Central Asia to confer the title of king on its ruler—a grand Imperial gesture reminiscent of the great days of Han. But this ghost of the Han Empire disappeared almost as soon as it had been evoked. Within two decades the Chin disintegrated through the struggles of rival clans. There followed an internecine war between the various Ssu-ma princes, collapse of the central government, decentralized military control of the provinces, famine, large-scale banditry, and messianic peasant movements.

The "barbarian" states of the north and the refugee states of the south

The era of "barbarian" invasions and rule. For the first time, the power vacuum was filled by non-Chinese forces. In 304 a Sinicized Hsiung-nu chieftain, Liu Yüan, assumed the title of king of Han and started the conquest of northern China. Operating from bases in western and southern Shansi, the Hsiung-nu armies, supported by local Chinese rebels, conquered the ancient homeland of Chinese civilization; the fall and destruction of the two capitals, Lo-yang (311) and Ch'ang-an (316), ended Chinese dynastic rule in the north for centuries. Although in the far northeast, in present-day Kansu, and in the inaccessible interior (Szechwan), Chinese local kingdoms did occasionally succeed in maintaining themselves for some time, the whole North China Plain itself became the scene of a bewildering variety of barbarian states, collectively known in Chinese historiography as the Shih-liu kuo (Sixteen Kingdoms).

The Tung (Eastern) Chin (317–420) and later dynasties in the south (420–589). During the whole medieval period it was the lower Yangtze region, the former territory of Wu, that remained the stronghold of a series of "legitimate" Chinese dynasties with Chien-k'ang as their capital. In 317 a member of the Chin Imperial family had set up a refugee regime at Chien-k'ang, consisting mainly of members of the exiled northern aristocracy. From the beginning, the Chin court was completely at the mercy of the "great families." Government in the Chinese south became a kind of oligarchy exercised by ever-changing groups and juntas of aristocratic clans. The so-called Six Dynasties (actually five: Tung Chin, 317–420; Liu-Sung, 420–479; Nan (Southern) Ch'i, 479–502; Nan Liang, 502–557; and Nan Ch'en, 557–589; the earlier kingdom of Wu, 222–280, is counted as the sixth) were politically and militarily weak and constantly plagued by internal feuds and revolts. Their annihilation (in 589) was postponed only by the internal division of the north and by the protection afforded by the Yangtze. To the very end, their opposition to the north remained alive, but occasional attempts to reconquer the ancient homeland were doomed to failure. The final reunification of China was to start from the northern plains, not from Chien-k'ang.

Although politically insecure, these dynasties were characterized by cultural brilliance: in literature, art, philosophy, and religion, they constituted one of the most creative periods in Chinese history. They reached their highest flowering under the long and relatively stable reign of the great protector of Buddhism, Wu-ti, the first emperor of the Nan Liang dynasty (reigned 502–549).

The Shih-liu kuo (Sixteen Kingdoms) in the north (303–439). The term Sixteen Kingdoms traditionally denotes the plethora of short-lived non-Chinese dynasties that from 303 came to rule the whole or parts of northern China. Many ethnic groups were involved, including ancestors of the Turks (such as the Hsiung-nu, possibly related to the Huns of late Roman history, and the Chieh), the Mongolians (Hsien-pei), and the Tibetans (Ti and Ch'iang). Most of these nomadic peoples, relatively few in number, had to some extent been Sinicized long before their ascent to power. In fact, some of them, notably the Ch'iang and the Hsiung-nu, had already since late Han times been allowed to live in the frontier regions within the Great Wall.

The barbarian rulers thus set up semi-Sinicized states, in which the foreign element constituted a military aristocracy and the nucleus of the armed forces. Since in administrative matters they lacked experience, and since their own tribal institutions were not adapted to the complicated task of ruling a large agrarian society, they had to make use of traditional Chinese ways of government. In doing so, they faced the dilemma that has ever since confronted foreign rulers on Chinese soil: the tension that existed between the need to preserve their own ethnic identity (and their position as Herrenvolk), on the one hand, and, on the other, the practical necessity of using Chinese literati and members of prominent Chinese families in order to rule at all. In spite of various and sometimes highly interesting experiments, most of these short-lived empires did not survive this tension. Significantly, the only one that proved to have more lasting power and that was able to unify the whole of northern China, the T'o-pa, or Northern Wei (386–534/535), was largely Sinicized within one century. In the late 5th century the court even forbade the use of the original T'o-pa language, dress, customs, and surnames. This policy of conscious acculturation was further symbolized by the transfer of the Northern Wei capital from the northern frontier region to the ancient Imperial residence of Lo-yang.

Sinicization of the foreign conquerors

Thus, toward the end of the period of division, the north had become more homogeneous as the result of a long process of adaptation. The most important factor in this process may have been the rehabilitation of the Chinese agrarian economy under the Northern Wei, stimulated by fiscal reform and redistribution of land (*c.* AD 500). The landed gentry again became the backbone of society, and the primitive rulers of nomadic origin simply had to conform to their way of life. Another factor may be sought in the intrinsic superiority of Chinese upper-class culture: in order to play the role of the "Son of Heaven," the barbarian court had to adopt the complicated rules of Chinese ritual and etiquette. In order to surround themselves with an aura of legitimacy, the foreign conquerors had to express themselves in terms of Chinese culture. In doing so, they invariably lost their own identity. History has repeated itself again and again: in this respect the 4th- and 5th-century Chieh and T'o-pa were but the forerunners of the Ch'ing, or Manchu, rulers in the 19th century.

In the early 6th century the Wei was divided between the Sinicized court and a faction of the nobility desperate to preserve its T'o-pa identity. Soon after 520 the Wei Empire disintegrated into rival northeastern and northwestern successor states. Northern China again became a battlefield for several decades. The Pei (Northern) Chou (557–581), strategically based in the rich basin of the Wei River, reunified the north (577). Four years later Yang Chien (better known by the name Wen-ti), a general of mixed Chinese and barbarian descent (but claiming to be a pure-blooded Chinese), usurped the throne and founded the Sui dynasty. In 589, having consolidated his regime, he crossed the Yangtze River and overthrew the last of the Chinese dynasties at Chien-k'ang. After almost four centuries of division and political decay, China was again united under one central government, which, in spite of its short duration, would lay the foundation of the great T'ang Empire.

INTELLECTUAL AND RELIGIOUS TRENDS

Confucianism and philosophical Taoism. The social and political upheaval of the late 2nd and 3rd centuries AD was accompanied by intense intellectual activity. During the Han period, Confucianism had been slowly adopted as an ideology and had gradually come to provide the officially accepted norms, morals, and ritual and social behaviour regulating the relations between ruler and subject.

By the beginning of the 3rd century, however, Confucianism had lost its prestige: it had obviously failed to save the empire from disintegration or to safeguard the privileges of the ruling elite. Disappointed members of the scholar-official class started to look elsewhere. Thus, in the 3rd century there was a revival of various all-but-forgotten schools of thought: Legalism, with its insistence upon harsh measures, intended to reestablish law and order; Mohism and the ancient school of Dialecticians; and, above all, a renewed interest in the earliest Taoist philosophers, Lao-tzu and Chuang-tzu. In general, this movement did not mean a return to ancient Taoist quietism and consequently a rejection of Confucianism. With the breakdown of the elaborate scholastic doctrine that had formed the official Han ideology, Confucianism had been deprived of its metaphysical superstructure, and this

vacuum was now filled by a whole set of philosophical ideas and speculations, largely of Taoist provenance.

Ming-chiao and Hsüan Hsüeh

Within this movement, two trends came to dominate the intellectual life of the cultured minority. One of these was closely related to the practical affairs of government and stressed the importance of social duties, ritual, law, and the study of human characteristics. This mixture of Confucian and Legalist notions was called *ming-chiao,* "the doctrine of names" ("names" in ancient Confucian parlance designating the various social functions—father, ruler, subject, etc.—that an individual could have in society). The other trend was marked by a profound interest in ontological and metaphysical problems: the quest for a permanent substratum (called *t'i,* "substance") behind the world of change (called *yung,* "function"). It started from the assumption that all temporally and spatially limited phenomena—anything "nameable"; all movement, change, and diversity; in short, all "being"—is produced and sustained by one impersonal principle, which is unlimited, unnameable, unmoving, unchanging, and undiversified. This important movement, which found its scriptural support both in Taoist and in drastically reinterpreted Confucian sources, was known as Hsüan Hsüeh ("Dark Learning"); it came to reign supreme in cultural circles, especially at Chien-k'ang during the period of division, and represented the more abstract, unworldly, and idealistic tendency in early medieval Chinese thought.

The proponents of Hsüan Hsüeh undoubtedly still regarded themselves as true Confucians. To them, Confucius was not simply the great teacher who had fixed the rules of social behaviour for all time but was the enlightened sage who had inwardly recognized the ultimate reality but had kept silent about it in his worldly teachings, knowing that these mysteries could not be expressed in words. Hence, his doctrine was supposed to be an expedient, a mere set of ad hoc rules intended to answer the practical needs of the times. This concept of "hidden saintliness" and the "expedient" character of the canonical teachings came to play a very important role in upper-class Buddhism.

Hsüan Hsüeh is sometimes referred to by the term Neo-Taoism, but this confuses the issue. It was both created by and intended for literati and scholar-officials—not Taoist masters and hermits. The theories of such thinkers as Hsi K'ang (223–262), who, with their quest for immortality and their extreme antiritualism, were much nearer to the spirit of Taoism, hardly belong to the sphere of Hsüan Hsüeh, and the greatest Taoist author of this period, Ko Hung (*c.* 283–330), was clearly opposed to these mystic speculations.

The popularity of Hsüan Hsüeh was closely related to the practice of "pure conversation" (*ch'ing-t'an*), a special type of philosophical discourse much in vogue among the cultured upper class from the 3rd century onward. In the earliest phase, the main theme of such discussion—a highly formalized critique of the personal qualities of well-known contemporaries—still had a concrete function in political life ("characterization" of persons was the basis of recommendation of clients for official posts and had largely taken the place of the earlier methods of selection of officials by court examinations). By the 4th century, however, *ch'ing-t'an* meetings had evaporated into a refined and very exclusive pastime of the aristocratic elite, a kind of salon in which "eloquent gentlemen" expressed some philosophical or artistic theme in elegant and abstruse words. It is obvious that much of Hsüan Hsüeh had become divorced from the realities of life and afforded an escape from it.

True Confucianism had thus lost much of its influence. In the north the not yet Sinicized "barbarian" rulers were interested in Confucianism mainly as a system of court ritual; ideologically, they were more attracted by the magical powers of Buddhist and Taoist masters. In the south the disillusioned aristocratic exiles, doomed by circumstances to lead a life of elegant inactivity, had little use for a doctrine that preached the duties of government and the regulation of human society as its highest goals, although many families preserved Confucian learning and clung to Confucian mores. In this period of internal division and political weakness, Confucianism had to hibernate; soon after the Sui had reunited the empire, it would wake up again.

Taoism. The suppression of the Yellow Turbans and other Taoist religious movements in AD 184 had left the Taoist church decapitated. With the elimination of its highest leadership, the movement had fallen apart into many small religious communities or parishes, each led by a local Taoist master (*tao-shih*), assisted by a council of wealthy Taoist laity. Under such circumstances, local Taoist masters could easily become leaders of independent sectarian movements. They could also, in times of unrest, use their charismatic power to play a leading part in local rebellions. In the early medieval period, Taoism at the grass-roots level continued to play this double role: it had an integrating function by providing spiritual consolation and ritualized forms of communal activity, but it could also play a disintegrating role as a potential source of subversive movements. The authorities naturally were well aware of this. Taoist rebellions periodically broke out in this period; and, although some masters occasionally became influential at court, the governments, both northern and southern, maintained a cautious reserve toward the Taoist religion. It was never stimulated and patronized to an extent comparable with Buddhism.

Development of sectarian movements

It would be wrong to speak of Taoism as a popular religion. Taoism counted its devotees even among the highest nobility. In view of the expensive ceremonies, the costly ingredients used in Taoist alchemy (notably cinnabar), and the almost unlimited amount of spare time required from the serious practitioner, one may assume that only the well-to-do were able to follow the road toward salvation. But they were mostly individual seekers; in the 3rd and 4th centuries there gradually grew a distinction between individual (and mainly upper-class) Taoism and the popular, collective creed of the simple devotees. In fact, Taoism has always been a huge complex of many different beliefs, cults, and practices. Most of these can be traced back to Tung Han times; after the 3rd century they were influenced more and more by Buddhism.

The basic ideal of Taoist religion—the attainment of bodily immortality in a kind of indestructible "astral body" and the realization of the state of *hsien,* or Taoist "immortal"—remained alive. It was to be pursued by a series of individual practices: dietary control, gymnastics, good deeds, and meditation and visualization of the innumerable gods and spirits that were supposed to dwell inside the microcosmos of the body. Famous literati, such as the poet Hsi K'ang (223–262) and the calligrapher Wang Hsi-chih (321–379), devoted much of their life to such practices. They combined various methods, ranging from mystic self-identification with the all-embracing Tao to the use of charms and experiments in alchemy.

During the 4th century the development of Taoism seems to have reached a new stage. At that time in southern China there was already an ancient school of esoteric learning, exemplified by Ko Hung. The retreat of the Chin to southern China in the early 4th century brought to that region the organized religion and priesthood that had arisen in the north and west during the Tung Han. In this context, new priestly cults arose in the south, their teaching connected with a series of revelations, the first through Yang Hsi, which led to the formation first of the Shang-ch'ing sect and later to the rival Ling-pao sect. By the end of the period of division, Taoism had its own canons of scriptural writings, much influenced by Buddhist models but forming a quite independent religious tradition.

Popular Taoist ceremonies

The other, collective, and more popular form of Taoism, practiced in the communities or parishes throughout the country, was characterized by communal ceremonies (*chai,* "fasting sessions," and *ch'u,* "banquets") held by groups of Taoist families under the guidance of the local master, both on fixed dates and on special occasions. The purpose of such meetings was the collective elimination of sins (evil deeds being considered as the main cause of sickness and premature death) through incantations, deafening music, fasting, and the display of penance and remorse. The gatherings sometimes lasted several days and nights, and, according to the indignant reports of their Buddhist adversaries, they were ecstatic and sometimes even orgias-

tic. The allegation of sexual excesses and promiscuity may have been stimulated by the fact, unknown in Confucian and Buddhist ritual, that in Taoist meetings both men and women took part.

The Taoist parish as an organization and the Taoist master who led it relied on two sources of income: the presents made by devotee families at ceremonial gatherings and the regular "Heavenly tax," or yearly contribution of five bushels of rice, which every family was due to pay on the seventh day of the seventh month. The office of Taoist master was hereditary, within one family; in the early centuries Taoist priests usually married. Because Buddhist influence also increased at this humble level, however, the *tao-shih* more and more came to resemble the Buddhist clergy, especially since most Taoist priests, at least from the 5th century onward, went to live in Taoist monasteries with their wives and children. In the 6th century, when Buddhism became paramount, some Taoist leaders introduced celibacy; in Sui times the unmarried state had become general, and the Taoist clergy with its monks and nuns had evolved into a counterpart of the Buddhist *saṅgha*. Unlike Buddhist monasteries, the Taoist monasteries and clergy never developed great economic power.

In spite of their resemblance or, perhaps, because of it, the two creeds were bitterly opposed throughout the period. Taoist masters were often involved in anti-Buddhist propaganda and persecution. As an answer to Buddhist claims of superiority, Taoist masters even developed the curious theory that the Buddha had been only a manifestation of Lao-tzu, who had preached to the Indians a debased form of Taoism, which naturally should not be reintroduced into China; this theme can be traced in Buddhist and Taoist polemic literature from the 4th to the 13th century.

The rise of Buddhism

Buddhism. The Buddhist age of China began in the 4th century. Several factors contributed to the extraordinary expansion and absorption of the foreign religion after about 300, both in the Chinese south and in the occupied north. A negative factor was the absence of a unified Confucian state, which naturally would be inclined to suppress a creed whose basic tenets (notably the monastic life and the pursuit of individual salvation outside family and society) were clearly opposed to the ideals of Confucianism. The popularity of Hsüan Hsüeh was a positive and powerful factor. Especially in the south, Mahāyāna Buddhism, thoroughly amalgamated with Hsüan Hsüeh, was preached by cultured monks in the circles of the Chien-k'ang aristocracy, where it became extremely popular.

Another stimulus for the growth of Buddhism was the relative security and prosperity of monastic life. In a countryside devastated by war and rebellion, innumerable small peasants preferred to give up their independence and to avoid the scourges of heavy taxation, forced labour, and deportation by joining the large estates of the nobility as serfs, where they would get at least a minimum of protection. This process of tax evasion and the consequent extension of the manorial system also stimulated the growth of Buddhist monasteries as landowning institutions, peopled with both monks and families of hereditary temple serfs. By the beginning of the 6th century the monasteries had become an economic power of the first order, which, moreover, enjoyed special privileges (such as exemption from taxes). This, indeed, became a main source of tension between clergy and government and occasionally led to anti-Buddhist movements and harsh restrictive measures imposed upon the Buddhist church (446–452 and again in 574–578).

The monastic life attracted many members of the gentry as well. In these times of turmoil, the official career was beset with dangers, and the monastery offered a hiding place to literati who tried to keep clear of the intrigues and feuds of higher official circles; thus the ancient Chinese ideal of the retired scholar merged with the new Buddhist ideal of the monastic life. Many large monasteries thereby became centres of learning and culture and so became even more attractive to members of minor gentry families, for whom the higher posts in government in any event would be unattainable. Buddhist institutions offered a kind of "internal democracy"—a fact of great social importance in the history of class-ridden medieval China. Finally, Buddhism was patronized by most of the "barbarian" rulers in the north. At first, they were mainly attracted by the pomp and magical power of Buddhist ritual. Later, other motivations were added to this. Unwilling to rely too much upon Chinese ministers with their following of clan members and clients, they preferred to make use of Buddhist masters, who as unmarried individuals were totally dependent on the ruler's favour. Ideologically, Buddhism was less "Chinese" than Confucianism, especially in the north, where the connections with Central Asia constantly reinforced its international and universalistic character. This peculiar "Sino-barbarian" nature of northern Buddhism with its foreign preachers and its huge translation projects strongly contrasts with the south, where Buddhism in the 4th century was already fully domesticated.

Because of all these circumstances, the large-scale development of Chinese Buddhism started only after the barbarian invasions of the early 4th century. In the 3rd century the picture did not basically differ from Han times: there are indications that Buddhism was still largely a religion of foreigners on Chinese soil (apart from some activity involving the translation of Buddhist scriptures). But by the 4th century the picture was changing. At the southern Chinese court in Chien-k'ang there was forming a clerical elite of Chinese monks and propagators of a completely Sinicized Buddhism, strongly amalgamated with Hsüan Hsüeh, and their sophisticated creed was being spread among the southern gentry. Starting at Chien-k'ang and in northern Chekiang (the Hang-chou region), this trend was further developed in the late 4th and early 5th centuries in other centres throughout the middle and lower Yangtze Basin. The highest flowering of this uniquely "Chinese" type of Buddhism took place in the early 5th century.

In the north the climax of Buddhist activity and Imperial patronage occurred under the Wei, especially after the beginning of their policy of conscious Sinicization. The T'o-pa court and the great families vied with each other in building temples and granting land and money to the monasteries; the monumental cave temples at Yün-kang are lasting proof of this large-scale Imperial protection. This also had its dark side: in the north the Buddhist clergy became closely tied with secular government, and the lavish treatment of the church was counterbalanced by repeated attempts at government control. It may also be noted that the north remained open to influences brought by traveling monks from Central Asia, and an enormous amount of Indian Buddhist texts of all schools and eras was translated.

Popular Buddhism

Little is known of the beginnings of popular Buddhism. Among the masses there was, to judge from Taoist materials, an intense mingling of Buddhist and popular Taoist notions and practices, such as communal festivals and the worship of local Taoist and Buddhist saints. At this level, simple devotionalism was no doubt far more influential than the scriptural teachings. It is also possible that the oral recital of Buddhist scriptures (mainly edifying tales) had already inspired the development of vernacular literature.

In any event, the constant amalgamation of Buddhism, Taoism, and the innumerable local cults whose history went back into high antiquity was to continue for centuries, eventually producing an amorphous mass of creeds and practices collectively known as Chinese popular religion. (E.Z./D.C.T.)

The Sui dynasty

The Sui dynasty (581–618), which reunified China after nearly four centuries of political fragmentation during which the north and south had developed in different ways, played a part far more important than its short span would suggest. In the same way that the Ch'in rulers of the 3rd century BC had unified China after the Chan-kuo (Warring States) period, so the Sui brought China together again and set up many institutions that were to be adopted by their successors, the T'ang. Like the Ch'in, however, the Sui overstrained their resources and fell. And also as in the case of the Ch'in, traditional history has judged the Sui somewhat unfairly; it has stressed the harshness of the

Sui regime and the megalomania of its second emperor, giving too little credit for its many positive achievements.

Reign of Wen-ti

Wen-ti, the founder (reigned 581–604) of the Sui dynasty, was a high-ranking official at the Pei (Northern) Chou court, a member of one of the powerful northwestern aristocratic families that had taken service under the successive non-Chinese royal houses in northern China and had intermarried with the families of their foreign masters. The Pei Chou had recently (577) reunified northern China by the conquest of the rival northeastern dynasty of Pei Ch'i. But political life in the northern courts was extremely unstable. The succession of an apparently deranged and irresponsible young emperor to the Chou throne in 578 set off a train of court intrigues, plots, and murders. Wen-ti was able to install a child as puppet emperor and then to seize the throne for himself.

In control of all of northern China and in command of formidable armies, he immediately set about establishing order within his frontiers. He built himself a grand new capital, Ta-hsing, close to the site of the old Ch'in and Han capitals, a city erected very quickly with a prodigal use of compulsory labour. This great city remained (under the name Ch'ang-an) the capital of the Sui and T'ang dynasties and the principal seat of government until the beginning of the 10th century.

Wen-ti also took quick action to protect the frontiers of his new state. China during the 6th century had a formidable northern neighbour in the Turks (T'u-chüeh), who controlled the steppe from the borders of Manchuria to the frontiers of the Byzantine and Sāsānian empires. At the time of Wen-ti's seizure of power, the Turks were splitting into two great empires, an eastern one dominating the Chinese northern frontier from Manchuria to Kansu, and a western one stretching in a vast arc north of the Tarim Basin into Central Asia. Wen-ti encouraged this split by supporting the khan of the western Turks, Tardu. Throughout his reign Wen-ti also pursued a policy of encouraging factional strife among the eastern Turks. At the same time he strengthened his defenses in the north by repairing the Great Wall. In the northwest in the area around the Koko Nor (Blue Lake), he defeated the T'u-yü-hun people, who from time to time raided the border territories.

By the late 580s Wen-ti's state was stable and secure enough for him to take the final step toward the reunification of the whole country. In 587 he dethroned the Emperor of the Hou (Later) Liang, the state that had ruled the middle Yangtze Valley as a puppet of the Pei Chou since 555. In 589 he overwhelmed the last southern dynasty, the Ch'en, which had put up only token resistance. Several rebellions against the Sui regime subsequently broke out in the south, but these were easily quelled. Wen-ti now ruled over a firmly reunited empire.

WEN-TI'S INSTITUTIONAL REFORMS

Wen-ti's achievement consisted of much more than strengthening and reunifying the empire. He provided it with uniform institutions and established a pattern of government that survived into the T'ang dynasty and beyond. A hardworking administrator, he employed a number of extremely able ministers who combined skill in practical statecraft with a flexible approach to ideological problems. They revived the Confucian state rituals to win favour with the literati and to establish a link with the empire of the Han; and at the same time they fostered Buddhism, the dominant religion of the south, attempting to establish the Emperor's image as an ideal Buddhist saint-king.

Wen-ti's lasting success, however, was in practical politics and institutional reforms. In the last days of the Pei Chou he had been responsible for a revision of the laws, and one of his first acts on becoming emperor was to promulgate a penal code, the New Code of 581. In 583 his ministers compiled a revised code, the K'ai-huang code, and administrative statutes. These were far simpler than the laws of the Pei Chou, and more lenient. Considerable pains were taken to ensure that local officials studied and enforced the new laws. Toward the end of Wen-ti's reign, when neo-Legalist political advisers gained ascendancy at court, the application of the laws became increasingly strict. The K'ai-huang code and statutes have not survived, but they provided the pattern for the T'ang code, the most influential body of law in the history of the Far East.

The legal code

The central government under Wen-ti developed into a complex apparatus of ministries, boards, courts, and directorates. The conduct of its personnel was supervised by another organ, the censorate. The emperor presided over this apparatus, and all orders and legislation were issued in his name. He was assisted by the heads of the three central ministries who acted as Counselors on State Affairs (I kuo-cheng). This system later provided the basic framework for the central government of the early T'ang.

Even more important, he carried out a sweeping reform and rationalization of local government. The three-level system of local administration inherited from Han times had been reduced to chaos during the 5th and 6th centuries by excessive subdivision; there were innumerable local districts, some of them very small and dominated by single families. Wen-ti created a simplified structure in which a much reduced number of counties was directly subordinated to prefectures. He also rationalized the chaotic rural administrative units into a uniform system of *hsiang*. Appointments to the chief offices in prefectures and counties were now made by the central government, rather than filled by members of local influential families as had been the practice. This reform ensured that local officials would be agents of the central government. It also integrated local officials into the normal pattern of bureaucratic promotion and in time produced a more homogeneous civil service.

Local government

Since the registration of population had fallen into chaos under the Pei Chou, a careful new census was carried out during the 580s. It recorded the age, status, and landed possessions of all the members of each household in the empire. On the basis of this census, the land allocation system employed under the successive northern dynasties since the end of the 5th century was reimposed. The tax system also followed the old model of head taxes levied in grain and silk at a uniform rate. The taxable age was raised, and the annual period of labour service to which all taxpayers were liable was reduced.

Wen-ti's government, in spite of his frontier campaigns and vast construction works, was very economical and frugal. By the 590s he had accumulated great reserves, and when the Ch'en territories were incorporated into his empire he was in a position to exempt the new population from 10 years of taxes to help ensure their loyalty.

The military system, likewise, was founded upon that of the northern dynasties; the Imperial forces were organized in militias. They served regular annual turns of duty but lived at home during the rest of the year and were largely self-supporting. Many troops were settled in military colonies on the frontiers to make the garrisons self-sufficient. Only when there was a campaign did the costs of the military establishment soar.

INTEGRATION OF THE SOUTH

The second Sui emperor, Yang-ti (reigned 604–617), has been depicted as a supreme example of arrogance, extravagance, and personal depravity who squandered his patrimony in megalomaniac construction projects and unwise military adventures. This mythical Yang-ti was to a large extent the product of the hostile record written of his reign shortly after his death. His reign began well enough, continuing the trends begun under Wen-ti. A further revision of the law code with a general reduction of penalties was carried out in 607.

Reign of Yang-ti

Yang-ti's principal achievement was the integration of the south more firmly into a unified China. There is little evidence that the south was ever completely brought into line with all the administrative practices of the north; the land allocation system seems unlikely to have been enforced there, and it is probable that the registration of the population, the essential foundation for the whole fiscal and military system, was only incompletely carried out in the old Ch'en territories. But Yang-ti himself was personally very much involved with the south. Married to a princess from the southern state of Liang, he had spent 591–600 as viceroy for the southern territories; their

successful integration into the Sui Empire after the initial wave of risings was largely due to his administration and to the generally clement policies employed in the former Ch'en territories.

His identification with the southern interest was one of the reasons he began the establishment of an examination system, based upon the Confucian Classical curriculum, as a means of drawing into the bureaucracy scholars from the southern and northeastern elites that had preserved traditions of Confucian learning. Hitherto, the court had been dominated by the generally less cultivated aristocratic families of mixed blood from northwestern China.

Yang-ti also attempted to weaken the predominance of the northwest by building a second great capital city at Lo-yang on the border of the eastern plains. This capital was not only distant from the home territories of the northwestern aristocrats but also easily provisioned from the rich farmlands of Hopeh and Honan. The new city was constructed in a great hurry, employing vast numbers of labourers both in building and in transporting the timber and other materials required. Yang-ti also built new palaces and an immense Imperial park, again with a prodigal use of labour.

Development of the canals

Another grandiose plan aimed at unifying the empire was to develop still further the canal system his father had begun in the metropolitan region and to construct a great canal linking Lo-yang with the Huai River and with the southern capital, Chiang-tu (Yang-chou), on the Yangtze. Much of this route followed existing rivers and ancient canals, but it was still an immense undertaking that employed masses of forced labourers working under appalling conditions. In 605 the canal system was opened between the capital at Lo-yang and the Yangtze, and in 610 it was extended south of the Yangtze to Hang-chou. At the same time, in preparation for campaigns in Manchuria and on the Korean frontier, another great canal was built northward from Lo-yang to the vicinity of modern Peking. By 611 the whole eastern plain had a canal system linking the major river systems of northern China and providing a trunk route from the Yangtze Delta to the northern frontier. The construction of these waterways was inordinately expensive, caused terrible suffering, and left a legacy of widespread social unrest; but in the long term the transportation system was to be a most important factor for maintaining a unified empire. Further hardship was caused by the mass levies of labour required to rebuild and strengthen the Great Wall in Shansi in 607 and 608 as a precaution against the resurgent eastern Turks.

FOREIGN AFFAIRS UNDER YANG-TI

In addition to these farsighted construction works, Yang-ti also pursued a very active foreign policy. An expedition to the south established sovereignty over the old Chinese settlement in Tongking and over the Champa state of Lin-yi in central Nam Viet. Several expeditions were sent to Taiwan, and relations with Japan were opened. The T'u-yü-hun people were driven out of Kansu and Tsinghai, and Sui colonies were established along the great western trade routes. The rulers of the various petty local states of Central Asia and the king of Kao-ch'ang (T'u-lu-p'an) became tributaries. A prosperous trade with Central Asia and the West grew up.

Relations with the Turks

The principal foreign threat was still posed by the Turks. These had now been completely split into the eastern Turks, who occupied most of the Chinese northern frontier, and the immensely powerful western Turks, whose dominions stretched westward to the north of the Tarim Basin as far as Sāsānian Persia and Afghanistan. During the early part of Yang-ti's reign the western Turks, whose ruler, Ch'u-lo, was half-Chinese, were on good terms with the Sui. In 610, however, Yang-ti supported a rival, She-kuei, who drove out Ch'u-lo. The latter took service, with an army of 10,000 followers, at Yang-ti's court. When Sui power began to wane after 612, the western Turks under She-kuei gradually replaced the Sui garrisons in Central Asia and established control over the states of the Tarim Basin. The eastern Turks had remained on good terms with the Sui, their khans being married to Chinese princesses. In 613 P'ei Chü, Yang-ti's principal agent in dealing with the foreign states of the north, attempted unsuccessfully to dethrone the eastern Turkish khan and split up his khanate. Relations with the Turks rapidly deteriorated, and in the last years of his reign Yang-ti had to contend with a hostile and extremely powerful neighbour.

Campaigns in Korea

His most costly venture was a series of campaigns in Korea. At that time Korea was divided into three kingdoms, of which the northern one, Koguryŏ, was the most important and powerful. It was hostile to the Chinese and refused to pay homage to Yang-ti. Yang-ti made careful preparations for a punitive campaign on a grand scale, including construction of the Yung-chi-ch'ü canal from Lo-yang to Peking. In 611 the canal was completed; a great army and masses of supplies were collected, but terrible floods in Hopeh delayed the campaign. During 612, 613, and 614 Yang-ti campaigned against the Koreans. The first two campaigns were unsuccessful and were accompanied by the outbreak of many minor rebellions in Shantung and southern Hopeh. The severe repression that followed led to outbreaks of disorder throughout the empire. In 614 yet another army was sent into Korea and threatened the capital at P'yŏngyang, but it had to withdraw without a decisive victory. These futile campaigns distracted Yang-ti's attention from the increasingly vital internal problems of his empire, involved an immense loss of life and matériel, and caused terrible hardships among the civilian population. They left the Sui demoralized, militarily crippled, and financially ruined.

At this point, Yang-ti decided to secure his relations with his northern neighbours. His envoy, P'ei Chü, had continued to intrigue against the eastern Turkish khan, in spite of the fact that the Sui were no longer in a position of strength. When in the summer of 615 Yang-ti went to inspect the defenses of the Great Wall, he was surrounded and besieged by the Turks at Yen-men; he was rescued only after a month of peril.

Fall of the Sui dynasty

Rebellions and uprisings soon broke out in every region of the empire. Late in 616 Yang-ti decided to withdraw to his southern capital of Chiang-tu, and much of northern China was divided among rebel regimes contending with one another for the succession to the empire. Yang-ti remained nominally emperor until the spring of 618, when he was murdered by members of his entourage at Chiang-tu. But by 617 the real powers in China had become the various local rebels: Li Mi in the area around Lo-yang, Tou Chien-te in the northeast, Hsüeh Chü in the far northwest, and Li Yüan (who remained nominally loyal but had established a local position of great power) in Shansi. At the beginning of 617 Li Yüan inflicted a great defeat on the eastern Turks and thus consolidated his local power in the impregnable mountainous area around T'ai-yüan. In the summer of 617 he raised an army and marched on the capital with the aid of the Turks and other local forces; Ch'ang-an fell at year's end. Hsüeh Chü's northwestern rebels were crushed, and the armies of Li Yüan occupied Szechwan and the Han River valley. A Sui prince, Kung-ti, was enthroned as "emperor" in 617, while Yang-ti was designated "retired emperor." In the summer of 618, after Yang-ti's death, Li Yüan (known by his temple name, Kao-tsu) deposed his puppet prince and proclaimed himself emperor of a new dynasty, the T'ang, which was to remain in power for nearly three centuries.

The T'ang dynasty

EARLY T'ANG (618–626)

Kao-tsu's struggle for control

When Kao-tsu became emperor (reigned 618–626), he was still only one among the contenders for control of the empire of the Sui. It was several years before the empire was entirely pacified. After the suppression of Hsüeh Chü and the pacification of the northwest, the T'ang had to contend with three principal rival forces: the Sui remnants commanded by Wang Shih-ch'ung at Lo-yang, the rebel Li Mi in Honan, the rebel Tou Chien-te in Hopeh, and Yü-wen Hua-chi, who had assassinated the previous Sui emperor Yang-ti and now led the remnants of the Sui's southern armies. Wang Shih-ch'ung set up a grandson of Yang-ti at Lo-yang as the new Sui emperor. Yü-wen Hua-chi led his armies to attack Lo-yang, and Wang Shih-

ch'ung persuaded Li Mi to return to his allegiance with the Sui and help him fight Yü-wen Hua-chi. Li Mi defeated Yü-wen Hua-chi's armies but depleted his own forces seriously. Wang Shih-ch'ung, seeing the chance to dispose of his most immediate rival, took over Lo-yang and routed Li Mi's forces. Li Mi fled to Ch'ang-an and submitted to the T'ang. In the spring of 619 Wang Shih-ch'ung deposed the puppet Sui prince at Lo-yang and proclaimed himself emperor.

The T'ang armies gradually forced him to give ground in Honan, and by 621 Kao-tsu's son Li Shih-min was besieging him in Lo-yang. At this time Wang Shih-ch'ung attempted to form an alliance with the most powerful of all the Sui rebels, Tou Chien-te, who controlled much of Hopeh and who had completed the defeat of Yü-wen Hua-chi's forces in 619. He held the key area of southern Hopeh, where he had successfully resisted both the T'ang armies and the forces of Wang and Li. Tou now agreed to come to the aid of the beleaguered Wang, but in the spring of 621 Li Shih-min attacked his army before it could lift the siege, routed it, and captured Tou. Wang then capitulated. The T'ang had thus disposed of its two most powerful rivals and extended its control over most of the eastern plain, the most populous and prosperous region of China.

This was not the end of resistance to the T'ang conquest. Most of the surrendered rebel forces had been treated leniently, and their leaders were often confirmed in office or given posts in the T'ang administration. Tou and Wang, however, were dealt with severely, Tou being executed and Wang murdered on his way to exile. At the end of 621 Tou's partisans in the northeast again rebelled under Liu Hei-t'a and recaptured most of the northeast. He was finally defeated by a T'ang army under the crown prince Chien-ch'eng at the beginning of 623. The prolonged resistance in Hopeh and the comparatively harsh T'ang conquest of the region were the beginning of resistance and hostility in the northeast that continued to some degree throughout the T'ang dynasty.

Resistance was not confined to the northeast. Liu Wu-chou in the far north of Shansi, who had been a constant threat since 619, was finally defeated and killed by his former Turkish allies in 622. In the south during the confusion at the end of the Sui, Hsiao Hsien had set himself up as emperor of Liang, controlling the central Yangtze region, Kiangsi, Kwangtung, and Annam. The T'ang army descended the Yangtze from Szechwan with a great fleet and defeated Hsiao Hsien's forces in two crucial naval battles. In 621 Hsiao Hsien surrendered to the T'ang, who thus gained control of the central Yangtze and the far south. The southeast was occupied by another rebel, Li Tzu-t'ung, based in Chekiang. He, too, was decisively defeated near modern Nanking at the end of 621. As had been the case with Hsiao Hsien's dominions, the southeast was incorporated into the T'ang Empire with a minimum of fighting and resistance. A last southern rebellion by Fu Kung-shih, a general who set up an independent regime at Nanking in 624, was speedily suppressed. After a decade of war and disorder, the empire was completely pacified and unified under the T'ang house.

Administration of the state. The T'ang unification had been far more prolonged and bloody than the Sui conquest. That the T'ang regime lasted for nearly three centuries rather than three decades, as with the Sui, was largely the result of the system of government imposed on the conquered territories. The emperor Kao-tsu's role in the T'ang conquest was understated in the traditional histories compiled under his successor T'ai-tsung (Li Shih-min; reigned 626–649), which portrayed T'ai-tsung as the prime mover in the establishment of the dynasty. T'ai-tsung certainly played a major role in the campaigns, but Kao-tsu was no figurehead. Not only did he direct the many complex military operations, but he also established the basic institutions of the T'ang state, which proved practicable not only for a rapidly developing Chinese society but also for the first centralized states in societies as diverse as those of Japan, Korea, Nam Viet, and the southwestern kingdom of Nan Chao.

The T'ang pattern of central control

The structure of the new central administration resembled that of Wen-ti's time, with its ministries, boards, courts, and directorates. There was no radical change in the dominant group at court. Most of the highest ranks in the bureaucracy were filled by former Sui officials, many of whom had been the new emperor's colleagues when he was governor in T'ai-yüan, or by descendants of officials of the Pei Chou, Pei Ch'i, or Sui, or of the royal houses of the northern and southern dynasties. The T'ang were related by marriage to the Sui royal house, and a majority of the chief ministers were related by marriage to either the T'ang or Sui Imperial family. The emperor's court was composed very largely of men of similar social origins. At this level the T'ang in its early years, like the Sui before it, continued the pattern of predominantly aristocratic rule that had dominated the history of the northern courts.

Kao-tsu also continued the pattern of local administration established under the Sui and maintained the strict control exercised by the central government over provincial appointments. In the first years after the T'ang conquest, many prefectures and counties were fragmented to provide offices for surrendered rebel leaders, surrendered Sui officials, and followers of the emperor. But these new local districts were gradually amalgamated and reduced in number, and by the 630s the pattern of local administration was very similar to that under the Sui. The merging of the local officials into the main bureaucracy, however, took time; ambitious men still looked upon local posts as "exile" from the main current of official promotion at the capital. Until well into the 8th century many local officials continued to serve for long terms, and the ideal of a regular circulation of officials prevailed only gradually.

Local government in early T'ang times had a considerable degree of independence, but each prefecture was in direct contact with the central ministries. In the spheres of activity that the administration regarded as crucial—registration, land allocation, tax collection, conscription of men for the army and for corvée duty, and the maintenance of law and order—prefects and county magistrates were expected to follow centrally codified law and procedure. They were, however, permitted to interpret the law to suit local conditions. Local influences remained very strong in the prefectures and counties. Most of the personnel in these divisions were local men, many of them members of families of petty functionaries.

Fiscal and legal system. Kao-tsu had inherited a bankrupt state, and most of his measures were aimed at simple and cheap administration. His bureaucracy was very small, at both the central and local levels. The expenses of government were largely met out of endowments of land attached to each office, the rents from which paid office expenses and salaries; by interest on funds of money allocated for similar purposes; and by services of taxpayers who performed many of the routine tasks of government as special duties, being exempted from tax in return.

Land distribution

Land distribution followed the equal allocation system used under the northern dynasties and the Sui. Every taxable male was entitled to a grant of land, part of which was to be returned when he ceased to be a taxpayer at 60, part of which was hereditary. The disposal of landed property was hedged around with restrictive conditions. Great landed estates were limited to members of the Imperial clan and powerful officials, to various state institutions, and to the Buddhist foundations. Although some land was hereditary, and more and more passed into the hereditary category with the passage of time, the lack of primogeniture meant that landholdings were fragmented among all the sons in each generation and thus tended to be small. It is unlikely that the system was ever enforced to the letter in any region, and it was probably never enforced at all in the south. But as a legal system governing registration of landed property and restricting its disposal, it remained in force until An Lu-shan's rebellion in the 8th century.

The tax system based on this land allocation system was also much the same as that under the Sui and preceding dynasties. Every adult male paid a head tax in grain and cloth and was liable to 20 days of work for the central government (normally commuted into a payment in cloth) and to a further period of work for the local authorities. Revenues were collected exclusively from the rural popu-

lation, the trade sector and the urban communities being exempt, and the system bore more heavily upon the poor, since it ignored the taxpayer's economic status.

The Sui had made a somewhat desultory attempt to provide China with a unified coinage. Kao-tsu set up mints and began the production of a good copper currency that remained standard throughout the T'ang era. But cash was in short supply during most of the 7th century and had to be supplemented by standard-sized lengths of silk. Counterfeiting was rife, particularly in the Yangtze Valley where the southern dynasties had supported a more highly monetized economy, and where the governments had exploited commerce as a source of revenue.

Law code

Kao-tsu also undertook a new codification of all centralized law, completed in 624. It comprised a code that embodied what were considered basic, unchanging normative rules, prescribing fixed penalties for defined offenses; statutes, comprising the general body of universally applicable administrative law; regulations, or codified legislation supplementary to the code and statutes; and ordinances, detailed procedural laws supplementing the statutes and issued by the departments of the central ministries. Under the early T'ang this body of codified law was revised every 20 years or so. The systematic effort to maintain a universally applicable codification of law and administrative practice was essential to the uniform system of administration that the T'ang succeeded in imposing throughout its diverse empire. The T'ang code proved remarkably durable. It was still considered authoritative as late as the 14th century and was used as a model by the Ming. It was also adopted with appropriate modifications in Japan in the early 8th century and by the Koreans and the Vietnamese at a much later date.

Kao-tsu thus laid down, in the very first years of the 7th century, institutions that survived until the middle of the 8th century. These provided strong central control, a high level of administrative standardization, and very economical administration.

THE PERIOD OF T'ANG POWER (626–755)

Two of Kao-tsu's sons were rivals for the succession: the crown prince Chien-ch'eng and Li Shih-min, the general who had played a large part in the wars of unification. Their rivalry, and the factional strife it generated, reached a peak in 625–626 when it appeared that Chien-ch'eng was likely to succeed. In a military coup, Li Shih-min murdered Chien-ch'eng and another of his brothers and forced his father to abdicate in his favour. He succeeded to the throne in 626 and is known by his temple name, T'ai-tsung.

Reign of T'ai-tsung

The "era of good government." The reign of T'ai-tsung (626–649), known traditionally as the "era of good government of Chen-kuan," was not notable for innovations in administration. Generally, his policies developed and refined those of his father's reign. The distinctive element was the atmosphere of his administration and the close personal interplay between the sovereign and his unusually able team of Confucian advisers. It approached the Confucian ideal of a strong, able, energetic, yet fundamentally moral king seeking and accepting the advice of wise and capable ministers, advice that was basically ethical rather than technical. Some important changes in political organization were begun during his reign and were continued throughout the 7th century. The court remained almost exclusively the domain of men of aristocratic birth. But T'ai-tsung attempted to balance the regional groups among the aristocracy so as to prevent the dominance of any single region. They comprised the Kuan-lung group from the northwest, the Tai-pei group from Shansi, the Shantung group from Hopeh, and the southern group from the Yangtze Valley. The most powerful Hopeh clans were excluded from high office, but T'ai-tsung employed members of each of the other groups and of the lesser northeastern aristocracy in high administrative offices as well as in his consultative group of scholars.

A second change was the use of the examination system on a large scale. The Sui examinations had already been reestablished under Kao-tsu, who had also revived the Sui system of high-level schools at the capital. Under T'ai-tsung the schools were further expanded and new ones established. Measures were taken to standardize their curriculum; an official orthodox edition of the Classics with a standard commentary was completed in 638. The schools at the capital were mostly restricted to the sons of the nobility and of high-ranking officials. Other examination candidates, however, came from the local schools. The examinations were in principle open to all, but they provided relatively few new entrants to the bureaucracy. Most officials still entered service by other means—by hereditary privilege as sons of officials of the upper ranks or by promotion from the clerical service or the guards. The examinations demanded a high level of education in the traditional curriculum and were largely used as an alternative method of entry by younger sons of the aristocracy and by members of lesser families with a scholar-official background. Moreover, personal recommendation, the lobbying of examiners, and often a personal interview by the emperor played a large part. Even in late T'ang times, not more than 10 percent of officials were recruited by the examinations. The main effect of the examination system in T'ang times was to bring into being a highly educated court elite within the bureaucracy, to afford access to the upper levels of the bureaucracy for members of locally prominent clans, and in the long term to break the monopoly of political power held by the upper aristocracy. The employment of persons dependent for their position on the emperor and the dynasty, rather than upon birth and social standing, made it possible for the T'ang emperors to establish their own power and independence.

The examination system

In the early years there was a great debate as to whether the T'ang ought to reintroduce the feudal system used under the Chou and the Han, by which authority was delegated to members of the Imperial clan and powerful officials and generals who were enfeoffed with hereditary territorial jurisdictions. T'ai-tsung eventually settled on a centralized form of government through prefectures and counties staffed by members of a unified bureaucracy. The T'ang retained a nobility, but its "fiefs of maintenance" were merely lands whose revenues were earmarked for its use and gave it no territorial authority.

T'ai-tsung continued his father's economic policies, and government remained comparatively simple and cheap. He attempted to cut down the bureaucratic establishment at the capital and drastically reduced the number of local government divisions. The country was divided into 10 provinces, which were not permanent administrative units but "circuits" for occasional regional inspections of the local administrations; these tours were carried out by special commissioners, often members of the censorate, sent out from the capital. This gave the central government an additional means of maintaining standardized and efficient local administration. Measures to ensure tax relief for areas stricken by natural disasters, and the establishment of relief granaries to provide adequate reserves against famine, helped to ensure the prosperity of the countryside. T'ai-tsung's reign was a period of low prices and general prosperity.

Foreign policy

T'ai-tsung was also successful in his foreign policy. In 630 the eastern Turks were split by dissension among their leadership and by the rebellion of their subject peoples. Chinese forces invaded their territories, totally defeated them, and captured their khan, and T'ai-tsung was recognized as their supreme sovereign, the "Heavenly khan." Many of the surrendered Turks were settled on the Chinese frontier, and many served in the T'ang armies. A similar policy of encouraging internal dissension was later practiced against the western Turks, who split into two separate khanates for a while. In 642–643 a new khan reestablished a degree of unified control with Chinese support and agreed to become a tributary of the Chinese. To seal the alliance, T'ai-tsung married him to a Chinese princess.

The eclipse of Turkish power enabled T'ai-tsung to extend his power over the various small states of the Tarim Basin. By the late 640s a Chinese military administration had extended westward even beyond the limits of modern Sinkiang. To the north, in the region of the Orhon River and to the north of the Ordos Desert, the T'ang armies

defeated the Hsüeh-yen-t'o, former vassals of the eastern Turks, who became T'ang vassals in 646. The T'u-yü-hun in the region around Koko Nor (Blue Lake) caused considerable trouble in the early 630s. T'ai-tsung invaded their territory in 634 and defeated them, but they remained unsubdued and invaded Chinese territory several times.

The Chinese western dominions now extended farther than in the great days of the Han. Trade developed with the West, with Central Asia, and with India. The Chinese court received embassies from Sāsānian Persia and from the Byzantine Empire. The capital was thronged with foreign merchants and foreign monks and contained a variety of non-Chinese communities. The great cities had their Zoroastrian, Manichaean, and Nestorian temples, along with the Buddhist monasteries that had been a part of the Chinese scene for centuries.

T'ai-tsung's only failure in foreign policy was in Korea. The northern state of Koguryŏ had sent tribute regularly, but in 642 there was an internal coup; the new ruler attacked Silla, another T'ang vassal state in southern Korea. T'ai-tsung decided to invade Koguryŏ, against the advice of most of his ministers. The T'ang armies, in alliance with the Khitan in Manchuria and the two southern Korean states Paekche and Silla, invaded Koguryŏ in 645 but were forced to withdraw with heavy losses. Another inconclusive campaign was waged in 647, and the very end of T'ai-tsung's reign was spent in building a vast fleet and making costly preparations for a final expedition.

T'ai-tsung's last years also saw a decline in the firm grasp of the Emperor over politics at his court. In the 640s a bitter struggle for the succession developed when it became clear that the designated heir was mentally unstable. The court split into factions supporting various candidates. The final choice, Li Chih, prince of Chin (reigned 649–683; temple name Kao-tsung) was a weak character, but he had the support of the most powerful figures at court.

Rise of the empress Wu-hou. Kao-tsung was 21 when he ascended the throne. In his first years he was dominated by the remaining great statesmen of T'ai-tsung's court, above all by the Emperor's uncle Chang-sun Wu-chi. But real power soon passed from Kao-tsung into the hands of the empress Wu-hou, one of the most remarkable women in Chinese history. Wu-hou had been a low-ranking concubine of T'ai-tsung. She was taken into Kao-tsung's palace and, after a series of complex intrigues, managed in 655 to have the legitimate empress, Wang, deposed and herself appointed in her place. The struggle between the two was not simply a palace intrigue. Empress Wang, who was of noble descent, had the backing of the old northwestern aristocratic faction and of the great ministers surviving from T'ai-tsung's court. Wu-hou came from a family of lower standing from Tai-yüan. Her father had been one of Kao-tsu's original supporters, her mother a member of the Sui royal family. She seems to have been supported by the eastern aristocracy, by the lesser gentry, and by the lower ranking echelons of the bureaucracy.

Skillful intrigue of the empress Wu-hou

But her success was largely the result of her skill in intrigue, her dominant personality, and her utter ruthlessness. The deposed empress and another Imperial favourite were savagely murdered, and the next half century was marked by recurrent purges in which she hounded to death one group after another of real or imagined rivals. The good relationship between the emperor and his court, which had made T'ai-tsung's reign so successful, was speedily destroyed. Political life became precarious and insecure, at the mercy of the Empress' unpredictable whims. The first victims were the elder statesmen of T'ai-tsung's reign, who were exiled, murdered, or driven to suicide in 657–659. In 660 Kao-tsung suffered a stroke. He remained in precarious health for the rest of his reign, and Wu-hou took charge of the administration.

Although utterly unscrupulous in politics, she backed up her intrigues with policies designed to consolidate her position. In 657 Lo-yang was made the second capital. The whole court and administration were frequently transferred to Lo-yang, thus removing the centre of political power from the home region of the northwestern aristocracy. Ministries and court offices were duplicated; Lo-yang had to be equipped with all the costly public buildings needed for a capital. After Kao-tsung's death, Wu-hou took up permanent residence there. Kao-tsung and Wu-hou were obsessed by symbolism and religion. One favourite magician, holy man, or monk followed another. State rituals were radically changed. For symbolic reasons the names of all offices were altered, and the emperor took the new title of "Heavenly emperor."

The bureaucracy was rapidly inflated to a far greater size than in T'ai-tsung's time, many of the new posts being filled by candidates from the examination system who now began to attain the highest offices and thus to encroach on what had been the preserves of the aristocracy. Another blow at the aristocracy was struck by the compilation in 659 of a new genealogy of all the empire's eminent clans, which ranked families according to the official positions achieved by their members rather than by their traditional social standing. Needless to say, the first family of all was that of Wu-hou. The lower ranks of the bureaucracy, among whom the Empress found her most solid support, were encouraged by the creation of new posts, by greater opportunities for advancement, and by salary increases.

The Chinese were engaged in foreign wars throughout Kao-tsung's reign. Until 657 they waged continual war against the western Turks, finally defeating them and placing their territories as far as the valley of the Amu Darya under a nominal Chinese protectorate in 659–661. Kao-tsung also waged repeated campaigns against Koguryŏ in the late 650s and 660s. In 668 the T'ang forces took P'yŏngyang, the capital, and Koguryŏ was also placed under a protectorate. But by 676 rebellions forced the Chinese to withdraw to southern Manchuria, and all Korea was increasingly dominated by the rapidly expanding power of the southern Korean state of Silla. The eastern Turks, who had been settled along the northern border, rebelled in 679–681 and were quelled only after widespread destruction and heavy losses to the Chinese forces.

The most serious foreign threat in Kao-tsung's reign was the emergence of a new and powerful force to the west, the Tibetans (T'u-fan), a people who had exerted constant pressure on the northern border of Szechwan since the 630s. By 670 the Tibetans had driven the T'u-yü-hun from their homeland in the Koko Nor basin. The northwest had to be increasingly heavily fortified and garrisoned to guard against their repeated raids and incursions. After a series of difficult campaigns, they were finally checked in 679.

When Kao-tsung died in 683 he was succeeded by the young Chung-tsung, but Wu-hou was made empress dowager and immediately took control over the central administration. Within less than a year she had deposed Chung-tsung, who had shown unexpected signs of independence, and replaced him by another puppet emperor, Jui-tsung, who was kept secluded in the Inner Palace while Wu-hou held court and exercised the duties of sovereign.

In 684 disaffected members of the ruling class under Li Ching-yeh raised a serious rebellion at Yang-chou in the south, but this was speedily put down. The Empress instituted a reign of terror among the members of the T'ang royal family and officials, employing armies of agents and informers. Fear overshadowed the life of the court. The Empress herself became more and more obsessed with religious symbolism. She manipulated Buddhist scripture to justify her becoming sovereign and in 688 erected a Ming T'ang ("Hall of Light")—the symbolic supreme shrine to Heaven described in the Classics—a vast building put up with limitless extravagance. In 690 the Empress proclaimed that the dynasty had been changed from T'ang to Chou. She became formally the empress in her own right, the only woman sovereign in China's history. Jui-tsung, the Imperial heir, was given her surname, Wu; everybody with the surname Wu in the empire was exempted from taxation. Every prefecture was ordered to set up a temple in which the monks were to expound the notion that the Empress was an incarnation of Buddha. Lo-yang became the "holy capital," and the state cult was ceremoniously transferred there from Ch'ang-an. The remnants of the T'ang royal family who had not been murdered or banished were immured in the depths of the palace.

Wu-hou enthroned

Destructive and demoralizing as the effects of her policies must have been at the capital and at court, there

is little evidence of any general deterioration of administration in the empire. By 690 the worst excesses of her regime were past. In the years after she had proclaimed herself empress she retained the services and loyalty of a number of distinguished officials. The court, however, was still unstable, with unending changes of ministers, and the Empress remained susceptible to the influence of a series of worthless favourites. After 700 she gradually began to lose her grip on affairs.

The external affairs of the empire had meanwhile taken a turn for the worse. The Tibetans renewed their warfare on the frontier. In 696 the Khitan in Manchuria rebelled against their Chinese governor and overran part of Hopeh. The Chinese drove them out, with Turkish aid, in 697. The Chinese reoccupied Hopeh under a member of the Empress' family and carried out brutal reprisals against the population. In 698 the Turks in their turn invaded Hopeh and were driven off only by an army under the nominal command of the deposed emperor, Chung-tsung, who had been renamed heir apparent in place of Jui-tsung. The military crisis had forced the Empress to abandon any plan to keep the succession within her own family.

New taxes

The expenses of the empire began to call for new taxes. These took the form of a household levy—a graduated tax based on a property assessment upon everyone from the nobility down, including the urban population—and a land levy collected on an acreage basis. These new taxes were to be assessed on the basis of productivity or wealth, rather than on a uniform per capita basis. Some tried to evade taxes by illegally subdividing their households to reduce their liabilities. There was a large-scale migration of peasant families fleeing from oppression and heavy taxation in the Hopeh and Shantung area. This migration of peasants, who settled as unregistered squatters on vacant land in central and southern China and no longer paid taxes, was accelerated by the Khitan invasion in the late 690s. Attempts to stop it were ineffectual.

By 705 the Empress, who was now 80, had allowed control of events to slip from her fingers. The bureaucratic faction at court, tired of the excesses of her latest favourites, forced her to abdicate in favour of Chung-tsung. The T'ang was restored.

Chung-tsung, however, also had a domineering wife, the empress Wei, who initiated a regime of utter corruption at court, openly selling offices. When the Emperor died in 710, probably poisoned by her, she tried to establish herself as ruler as Wu-hou had done before her. But Li Lung-chi, the future Hsüan-tsung, with the aid of Wu-hou's formidable daughter, T'ai-p'ing, and of the palace army, succeeded in restoring his father, Jui-tsung (the brother of Chung-tsung), to the throne. The Princess now attempted to dominate her brother, the Emperor, and there followed a struggle for power between her and the heir apparent. In 712 Jui-tsung ceded the throne to Hsüan-tsung but retained in his own hands control over the most crucial areas of government. A second coup, in 713, placed Hsüan-tsung completely in charge and resulted in Jui-tsung's retirement and in the princess T'ai-p'ing's suicide.

Prosperity and progress. Hsüan-tsung's reign (712–756) was the high point of the T'ang dynasty. It was an era of wealth and prosperity that saw institutional progress along with a flowering of the arts. Political life was at first dominated by the bureaucrats recruited through the examination system who had staffed the central government under Wu-hou. But a gradual revival of the power of the great aristocratic clans tended to polarize politics, a polarization that was sharpened by the Emperor's employment of a series of aristocratic specialists who reformed the empire's finances from 720 onward, often in the teeth of bureaucratic opposition.

Reign of Hsüan-tsung

After 720 a large-scale reregistration of the population produced a greatly increased number of taxpayers and restored state control over vast numbers of unregistered families. The new household and land taxes were expanded. In the 730s the canal system, which had been allowed to fall into neglect under Wu-hou and her successors, was repaired and reorganized so that the administration could transport large stocks of grain from the Yangtze region to the capital and to the armies on the northern frontiers. The south was at last financially integrated with the north. By the 740s the government had accumulated enormous reserves of grain and wealth. The tax and accounting systems were simplified, taxes and labour services reduced.

Some important institutional changes accompanied these reforms. The land registration, reorganization of transport, and coinage reform were administered by specially appointed commissions holding extraordinary powers, including the authority to recruit their own staff. These commissions were mostly headed by censors, and they and the censorate became centres of aristocratic power. The existence of these new offices reduced the influence of the regular ministries, enabling the emperor and his aristocratic advisers to circumvent the normal channels and procedures of administration.

Dominance of the aristocracy

After 736 the political dominance of the aristocracy was firmly reestablished. An aristocratic chief minister, Li Lin-fu, became a virtual dictator, his powers increasing as Hsüan-tsung in his later years withdrew from active affairs into the pleasures of palace life and the study of Taoism. In the latter part of his reign Hsüan-tsung, who had previously strictly circumscribed the power of the palace women to avoid a recurrence of the disasters of Wu-hou's time and had also excluded members of the royal family from politics, faced a series of succession plots. In 745 he fell deeply under the influence of a new favourite, the Imperial concubine Yang Kuei-fei. In 751–752 one of her relatives, Yang Kuo-chung, thanks to her influence with the Emperor, rapidly rose to rival Li Lin-fu for supreme power. After Li's death in 752 Yang Kuo-chung dominated the court. He had not, however, Li's great political ability nor his experience and skill in handling people.

Military reorganization. The most important new development in Hsüan-tsung's reign was the growth in the power of the military commanders. During Kao-tsung's reign the old militia system had proved inadequate for frontier defense and had been supplemented by the institution of permanent armies and garrison forces quartered in strategic areas on the frontiers. These armies were made up of long-service veterans, many of them non-Chinese cavalry troops, settled permanently in military colonies. Although these armies were adequate for small-scale operations, for a large-scale campaign an expeditionary army and a headquarters staff had to be specially organized and reinforcements sent in by the central government. This cumbersome system was totally unsuitable for dealing with the highly mobile nomadic horsemen on the northern frontiers.

Hostility of the Turks and Tibetans

At the beginning of Hsüan-tsung's reign the Turks threatened to become again a major power, rivaling China in Central Asia and along the borders. Mo-ch'o, the Turkish khan who had invaded Hopeh in the aftermath of the Khitan invasion in the time of Wu-hou and had attacked the Chinese northwest at the end of her reign, turned his attention northward. By 711 he controlled the steppe from the Chinese frontier to Transoxiana and appeared likely to develop a new unified Turkish empire. When he was murdered in 716 his flimsy empire collapsed. His successor, Bilge, tried to make peace with the Chinese in 718, but Hsüan-tsung preferred to try to destroy his power by an alliance with the southwestern Basmil Turks and with the Khitan in Manchuria. Bilge, however, crushed the Basmil and attacked Kansu in 720. Peaceful relations were established in 721–722. Bilge's death in 734 precipitated the end of Turkish power. A struggle among the various Turkish subject tribes followed, from which the Uighur emerged as victors. In 744 they established a powerful empire that was to remain the dominant force on China's northern border until 840. Unlike the Turks, however, the Uighur pursued a consistent policy of alliance with the T'ang. On several occasions Uighur aid, even though offered on harsh terms, saved the dynasty from disaster.

The Tibetans were the most dangerous foe during Hsüan-tsung's reign, invading the northwest annually from 714 on. In 727–729 the Chinese undertook large-scale warfare against them, and in 730 a settlement was concluded. But in the 730s fighting broke out again, and the Tibetans began to turn their attention to the T'ang territories in the Tarim Basin. Desultory fighting continued on the border

of Kansu until the end of Hsüan-tsung's reign. From 752 onward the Tibetans acquired a new ally in the Nan Chao state in Yunnan, which enabled them to exert a continuous threat along the entire western frontier.

The frontier commanders

In the face of these threats, Hsüan-tsung organized the northern and northwestern frontiers from Manchuria to Szechwan into a series of strategic commands or military provinces under military governors who were given command over all the forces in a large region. This system developed gradually and was formalized in 737 under Li Lin-fu. The frontier commanders controlled enormous numbers of troops: nearly 200,000 were stationed in the northwest and Central Asia and more than 100,000 in the northeast; there were well over 500,000 in all. The military governors soon began to exercise some functions of civil government. In the 740s a non-Chinese general of Sogdian and Turkish origin, An Lu-shan, became military governor first of one and finally of all three of the northeastern commands, with 160,000 troops under his orders. An Lu-shan had risen to power largely through the patronage of Li Lin-fu. When Li died, An became a rival of Yang Kuo-chung. As Yang Kuo-chung developed more and more of a personal stranglehold over the administration at the capital, An Lu-shan steadily built up his military forces in the northeast. The armed confrontation that followed (see below) nearly destroyed the dynasty.

During the 750s there was a steady reversal of T'ang military fortunes. In the far west the overextended Imperial armies had been defeated by the Arabs in 751 on the Talas River. In the southwest a campaign against the new state of Nan Chao in Yunnan had led to the almost total destruction of an army of 50,000 men. In the northeast the Chinese had lost their grip on the Manchuria–Korea border with the emergence of the new state of Parhae in place of Koguryŏ, and the Khitan and Hsi peoples in Manchuria constantly caused border problems. The Tibetans in the northwest were kept in check only by an enormously expensive military presence. The principal military forces were designed essentially for frontier defense.

Thus the end of Hsüan-tsung's reign found the state in a highly unstable condition, with central government dangerously dependent on a small group of men operating outside the regular institutional framework, and with an overwhelming preponderance of military power in the hands of potentially rebellious commanders on the frontiers, against whom the Emperor could put into the field only a token force of his own and the troops of those commanders who remained loyal.

THE LATE T'ANG (755–907)

Rebellion led by An Lu-shan

The rebellion of An Lu-shan in 755 marked the beginning of a new period. At first the rebellion had spectacular success. It swept through the northeastern province of Hopeh, captured the eastern capital, Lo-yang, early in 756, and took the main T'ang capital, Ch'ang-an, in July of the same year. The Emperor fled to Szechwan, and on the road his consort Yang Kuei-fei and other members of the Yang faction who had dominated his court were killed. Shortly afterward the heir apparent, who had retreated to Ling-wu in the northwest, himself usurped the throne. The new emperor, Su-tsung (reigned 756–762), was faced with a desperately difficult military situation. The rebel armies controlled the capital and most of Hopeh and Honan. In the last days of his reign Hsüan-tsung had divided the empire into five areas, each of which was to be the fief of one of the Imperial princes. Prince Yung, who was given control of the southeast, was the only one to take up his command; during 757 he attempted to set himself up as the independent ruler of the crucially important economic heart of the empire in the Huai and Yangtze valleys but was murdered by one of his generals.

An Lu-shan himself was murdered by a subordinate early in 757, but the rebellion was continued, first by his son and then by one of his son's generals, Shih Ssu-ming, and his son Shih Ch'ao-i. Not until 763 was it finally suppressed. The rebellion had caused great destruction and hardship, particularly in Honan. The final victory was made possible partly by the employment of Uighur mercenaries, whose insatiable demands remained a drain on the treasury well into the 770s; partly by the failure of the rebel leadership after the death of the able Shih Ssu-ming; and partly by the policy of clemency adopted toward the rebels after the decisive campaign in Honan in 762. The need for a speedy settlement was urged by the growing threat of the Tibetans in the northwest. The latter, allied with the Nan Chao kingdom in Yunnan, had exerted continual pressure on the western frontier and in 763 occupied the whole of modern Kansu. Late in 763 they actually took and looted the capital. They continued to occupy the Chinese northwest until well into the 9th century. Their occupation of Kansu signaled the end of Chinese power for almost a millennium in Sinkiang.

Provincial separatism. The post-rebellion settlement not only pardoned several of the most powerful rebel generals but also appointed them as Imperial governors in command of the areas they had surrendered. Hopeh was divided into four new provinces, each under surrendered rebels, while Shantung became the province of An Lu-shan's former garrison army from P'ing-lu in Manchuria, which had held an ambivalent position during the fighting. Within these provinces the central government held little power. The leadership was decided within each province, and the central government in its appointments merely approved faits accomplis. Succession to the leadership was frequently hereditary. For all practical purposes, the northeastern provinces remained semi-independent throughout the later part of the T'ang era. They had been among the most populous and productive parts of the empire, and their semi-independence was not only a threat to the stability of the central government but also represented a huge loss of revenue and potential manpower.

Breakdown of the central machinery

Provincial separatism also became a problem elsewhere. With the general breakdown of the machinery of central administration after 756, many of the functions of government were delegated to local administrations. The whole empire was now divided into provinces (*tao*), which formed an upper tier of routine administration. Their governors had wide powers over subordinate prefectures and counties. The new provincial governments were of two main types. In northern China (apart from the semi-autonomous provinces of the northeast, which were a special category) most provincial governments were military, their institutions closely modeled on those set up on the northern frontier under Hsüan-tsung. The military presence was strongest in the small frontier-garrison provinces that protected the capital, Ch'ang-an, from the Tibetans in Kansu and in the belt of small, heavily garrisoned provinces in Honan that protected China—and the canal from the Huai and Yangtze valleys, on which the central government depended for its supplies—from the semiautonomous provinces. Military governments were also the rule in Szechwan, which continued to be menaced by the Tibetans and Nan Chao, and in the far south in Ling-nan. In central and southern China, however, the provincial government developed into a new organ of the civil bureaucracy. The civil governors of the southern provinces were regularly appointed from the bureaucracy, and it became customary to appoint to these posts high-ranking court officials who were temporarily out of favour.

All the new provinces had considerable latitude of action, particularly during the reigns of Su-tsung and Tai-tsung, when central power was at a low ebb. There was a general decentralization of authority. The new provinces had considerable independence in the fields of finance, local government, law and order, and military matters.

Reign of Tai-tsung

Under Tai-tsung (reigned 762–779/780) the court was dominated by the Emperor's favourite, Yüan Tsai, and by the eunuchs who now began to play an increasing role in T'ang politics. A succession of eunuch advisers not only rivaled in influence the chief ministers but even exerted influence over the military in the campaigns of the late 750s and early 760s. Under Tai-tsung many of the regular offices of the administration remained unfilled, while the irregularities encouraged by Yüan Tsai and his clique in the appointment of officials led to an increasing use of eunuchs in secretarial posts and to their increasing dominance over the Emperor's private treasury.

The central government did achieve some success in

finance. The old fiscal system with its taxes and labour services had been completely disrupted by the breakdown of authority and by the vast movements of population. The revenues became more and more dependent upon additional taxes levied on cultivated land or on property. Increasingly the government attempted to raise revenue from the urban population. But its survival depended upon the revenues it drew from central China, from the Huai Valley, and from the lower Yangtze. These revenues were sent to the capital by means of a reconstructed and improved canal system maintained out of the new government monopoly on salt. By 780 the salt monopoly was producing a major part of the state's central revenues, in addition to maintaining the transportation system. The salt and transportation administration was controlled by an independent commission centred in Yang-chou near the mouth of the Yangtze, and this commission gradually took over the entire financial administration of southern and central China.

Taxes and rebellion

The weak Tai-tsung was succeeded by a tough, intelligent activist emperor, Te-tsung (reigned 779/780–805), who was determined to restore the fortunes of the dynasty. He reconstituted much of the old central administration and decided on a showdown with the forces of local autonomy. As a first step, in 780 he promulgated a new system of taxation under which each province was assessed a quota of taxes, the collection of which was to be left to the provincial government. This was a radical measure, for it abandoned the traditional concept of head taxes levied at a uniform rate throughout the empire and also began the assessment of taxes in terms of money.

The semi-independent provinces of the northeast saw this as a threat to their independence, and, when it became apparent that Te-tsung was determined to carry out consistently tough policies toward the northeast, reducing their armies and even denying them the right to appoint their own governors, the Hopeh provinces rebelled. From 781 to 786 there was a wave of rebellions not only in the northeastern provinces but also in the Huai Valley and in the area of the capital itself. These brought the T'ang even closer to disaster than had the An Lu-shan rising. The situation was saved because at a crucial moment the rebels fell out among themselves and because the south remained loyal. In the end, the settlement negotiated with the governors of Hopeh virtually endorsed the preceding status quo, although the court made some marginal inroads with the establishment of two small new provinces in Hopeh.

After this disaster, Te-tsung pursued a very careful and passive policy toward the provinces. Governors were left in office for long periods, and hereditary succession continued. But the latter part of Te-tsung's reign was a period of steady achievement. The new tax system was gradually enforced and proved remarkably successful; it remained the basis of the tax structure until Ming times. Revenues increased steadily, and Te-tsung left behind him a wealthy state. Militarily, he was also generally successful. The Tibetan threat was contained. Nan Chao was won from its alliance with the Tibetans. The garrisons of the northwest were strengthened. At the same time, Te-tsung built up large new palace armies, giving the central government a powerful striking force—numbering 100,000 men by the end of his reign. Command was given to eunuchs considered loyal to the throne. The death of Te-tsung in 805 was followed by the very brief reign of Shun-tsung, an invalid monarch whose court was dominated by the clique of Wang Shu-wen and Wang P'ei. They planned to take control of the palace armies from the eunuchs but failed.

Reign of Hsien-tsung

The struggle for central authority. Under Hsien-tsung (reigned 805/806–820) the T'ang regained a great deal of its power. Hsien-tsung, a tough and ruthless ruler who kept a firm hand on affairs, is notable chiefly for his successful policies toward the provinces. Rebellions in Szechwan (806) and the Yangtze Delta (807) were quickly put down. After an abortive campaign (809–810) that was badly bungled by a favourite eunuch commander, the court was again forced to compromise with the governors of Hopeh. A fresh wave of trouble came in 814–817 with a rebellion in Huai-hsi, in the upper Huai valley, that threatened the canal route. This uprising was crushed and the province divided up among its neighbours. The P'ing-lu army in Shantung rebelled in 818 and suffered the same fate. Hsien-tsung thus restored the authority of the central government throughout most of the empire. His success was based largely upon the palace armies. The fact that these were controlled by eunuchs placed a great measure of power in the Emperor's hands. Under his weak successors, however, eunuchs' influence in politics proved a disaster.

Hsien-tsung's restoration of central authority involved more than military dominance. It was backed by a series of institutional measures designed to strengthen the power of the prefects and county magistrates, as against their provincial governors, by restoring to them the right of direct access to central government and giving them some measure of control over the military forces quartered within their jurisdiction. In an important financial reform, the provincial government no longer had first call on all the revenue of the province, as some revenue went directly to the capital. The government also began the policy, continued throughout the 9th and 10th centuries, of cutting down and fragmenting the provinces. It strengthened its control over the provincial administrations through a system of eunuch army supervisors, who were attached to the staff of each provincial governor. These eunuchs played an increasingly important role, not merely as sources of information and intelligence but as active agents of the emperor, able to intervene directly in local affairs.

The balance of power within the central government had also been considerably changed. The emperor Te-tsung had begun to delegate a great deal of business, in particular the drafting of edicts and legislation, to his personal secretariat, the Hanlin Academy. Although the members of the Hanlin Academy were handpicked members of the bureaucracy, their positions as academicians were outside the regular official establishment. This eventually placed the power of decision and the detailed formulation of policy in the hands of a group dependent entirely upon the emperor, thus threatening the authority of the regularly constituted ministers of the court. The influence of the eunuchs also began to be formalized and institutionalized in the palace council; this provided the emperor with another personal secretariat, which controlled the conduct of official business and had close links with the eunuchs' command of the powerful palace armies.

The eunuchs

The eunuchs' influence in politics steadily increased. Hsien-tsung was murdered by some of his eunuch attendants, and henceforth the chief eunuchs of the palace council and the palace armies were a factor in nearly every succession to the T'ang throne; in some cases they had their own candidates enthroned in defiance of the previous emperor's will. The emperor Wen-tsung (reigned 826/827–840) sought to destroy the dominance of the eunuchs; his abortive schemes only demoralized the bureaucracy, particularly after the Sweet Dew coup of 835, which misfired and led to the deaths of several ministers and a number of other officials. But the apogee of the eunuchs' power was brief, ending with the accession of Wu-tsung in 840. Wu-tsung and his minister, Li Te-yü, managed to impose some restrictions on the eunuchs' power, especially in the military.

In the second half of the 9th century the central government became progressively weaker. In I-tsung's reign (859–873) there was a resurgence of the eunuchs' power and constant fratricidal strife between eunuchs and officials at court. From the 830s onward the first signs of unrest and banditry had appeared in the Huai Valley and Honan. From 856 trouble spread to the Yangtze Valley and the south. There were major uprisings led by K'ang Ch'üan-t'ai in southern Anhwei in 858 and by Ch'iu Fu in Chekiang in 859. The situation was complicated by a costly war against the Nan Chao kingdom on the borders of the Chinese protectorate in Annam, which later spread to Szechwan and dragged on from 858 until 866. After the suppression of the invaders, part of the garrison force that had been sent to Ling-nan mutinied and, under its leader, Pang Hsün, fought and plundered its way back to Honan, where it caused widespread havoc in 868 and 869, cutting the canal linking the capital to the loyal Yangtze and Huai provinces. In 870 war broke out again with Nan Chao.

I-tsung was succeeded by Hsi-tsung, a boy of 11 who was the choice of the palace eunuchs. He reigned from 873 to 888. Honan had repeatedly suffered serious floods. In 874 following a terrible drought, a wave of peasant risings began. The most formidable of them was led by Huang Ch'ao, who in 878 marched south and sacked Canton and then marched to the north, where he took Lo-yang in late 880 and Ch'ang-an in 881. Although Huang Ch'ao attempted to set up a regime in the capital, he proved cruel and inept. Hemmed in by loyal armies and provincial generals, in 883 he was forced to abandon Ch'ang-an and withdraw to Honan and then to Shantung, where he died in 884. His forces were eventually defeated with the aid of Sha-t'o Turks, although the T'ang court was left virtually powerless, its emperor a puppet manipulated by rival military leaders. The dynasty lingered on until 907, but the last quarter century was dominated by the generals and provincial warlords. With the progressive decline of the central government in the 880s and 890s, China fell apart into a number of virtually independent kingdoms. Unity was not restored until long after the establishment of the Sung dynasty.

End of the T'ang dynasty

CULTURAL DEVELOPMENTS

The influence of Buddhism. The T'ang emperors officially supported Taoism because of their claim to be descended from Lao-tzu, but Buddhism continued to enjoy great favour and lavish Imperial patronage through most of the period. The famous pilgrim Hsüan-tsang, who went to India in 629 and returned in 645, was the most learned of Chinese monks and introduced new standards of exactness in his many translations from Sanskrit. The most significant development in this time was the growth of new indigenous schools that adapted Buddhism to Chinese ways of thinking. Most prominent were the syncretistic T'ien-t'ai school, which sought to embrace all other schools in a single hierarchical system (even reaching out to include Confucianism), and the radically antitextual, antimetaphysical southern Ch'an (Zen) school, which had strong roots in Taoism. The popular preaching of the salvationist Pure Land sect was also important. After the rebellion of An Lu-shan, a nationalistic movement favouring Confucianism appeared, merging with the efforts of T'ien-t'ai Buddhism to graft Buddhist metaphysics onto Classical doctrine and lay the groundwork for the Neo-Confucianism of the Sung era.

In 843–845 the emperor Wu-tsung, a fanatical Taoist, decided to suppress Buddhism. One of his motives was economic. China was in a serious financial crisis, which Wu-tsung and his advisers hoped to solve by seizing the lands and wealth of the monasteries. The suppression was far-reaching: 40,000 shrines and temples—all but a select few—were closed; 260,000 monks and nuns were returned to lay life; vast acreages of monastic lands were confiscated and sold and their slaves manumitted. The suppression was short-lived, but irreparable damage was done to Buddhist institutions. Buddhism had already begun to lose intellectual momentum, and this attack upon it as a social institution marked the beginning of its decline in China.

The monastic communes

There were several types of monastic community. Official temples set up by the state had large endowments of land and property and large communities of monks who chose their own abbot and other officers. There were vast numbers of small village temples, shrines, and hermitages; these were often privately established, had little property, and were quite vulnerable to state policies. There were also private temples or "merit cloisters" established by great families, often in order that the family might donate its property and have it declared tax-exempt.

The monastic community was free of all obligations to the state. It was able to hold property without the process of division by inheritance that made the long-term preservation of individual and family fortunes almost impossible in T'ang times. It acquired its wealth from those taking monastic vows, from gifts of pious laymen, and from grants of lands by the state. The lands were worked by monastic slaves, by dependent families, by lay clerics who had taken partial vows but lived with their families, or by tenants. Monasteries also operated oil presses and mills. They were important credit institutions, supplying loans at interest and acting as pawnshops. They provided lodgings for travelers, operated hospitals and infirmaries, and maintained the aged. One of their most important social functions was primary education. The temples maintained their own schools, training the comparatively large proportion of the male population, which, although not educated to the standards of the Confucian elite or of the clergy, was nevertheless literate.

Trends in the arts. In literature the greatest glory of the T'ang period was its poetry. By the 8th century poets had broken away from the artificial diction and matter of the court poetry of the southern dynasties and achieved a new directness and naturalism. The reign of Hsüan-tsung (712–756)—known as Ming-huang, the Brilliant Emperor—was the time of the great figures of Li Po, Wang Wei, and Tu Fu. The rebellion of An Lu-shan and Tu Fu's bitter experiences in it brought a new note of social awareness to his later poetry. This appears again in the work of Po Chü-i (772–846), who wrote verse in clear and simple language. Toward the end of the dynasty a new poetic form, the *tz'u,* in a less regular metre than the five-word and seven-word *lu-shih* and meant to be sung, made its appearance. The *ku-wen,* or "ancient style," movement grew up after the rebellion of An Lu-shan, seeking to replace the euphuistic *p'ien-wen* ("parallel prose") then dominant. It was closely associated with the movement for a Confucian revival. The most prominent figures in it were Han Yü and Liu Tsung-yüan. At the same time came the first serious attempts to write fiction, the so-called *ch'uan-ch'i,* or "tales of marvels." Many of these T'ang stories later provided themes for the Chinese drama.

T'ang poets

The patronage of the T'ang emperors and the general wealth and prosperity of the period encouraged the development of the visual arts. Though few T'ang buildings remain standing, contemporary descriptions give some idea of the magnificence of T'ang palaces and religious edifices and the houses of the wealthy. Buddhist sculpture shows a greater naturalism than in the previous period, but there is some loss of spirituality. Few genuine originals survive to show the work of T'ang master painters such as Wu Tao-hsüan, who worked at Hsüan-tsung's court (712–756). As a landscape painter the poet Wang Wei was a forerunner of the *wen-jen,* or "literary man's," school of mystical nature painting of later times. The minor arts of T'ang, including ceramics, metalwork, and textiles, give expression to the colour and vitality of the life of the period. Printing appeared for the first time during T'ang. Apparently invented to multiply Buddhist scriptures, it was used by the end of the dynasty for such things as calendars, almanacs, and dictionaries.

Visual arts

SOCIAL CHANGE

Decline of the aristocracy. The late T'ang period saw the beginnings of social changes that did not reach their culmination until the 11th century. The most important of these was the change in the nature of the ruling class. Although from the early T'ang era the examination system had facilitated the recruitment into the higher ranks of the bureaucracy of persons from lesser aristocratic families, most officials continued to come from the established elite. Social mobility increased after the An Lu-shan rebellion: provincial governments emerged, their staffs in many cases recruited from soldiers of very lowly social origins, and specialized finance commissions were established, a large part of their personnel often recruited from the commercial community. The contending factions of the 9th-century court also employed irregular appointments to secure posts for their clients and supporters, many of whom came from comparatively lowly backgrounds.

Although the old aristocracy retained a grip on political power until very late in the dynasty, its exclusiveness and hierarchical pretensions were rapidly breaking down. It was finally extinguished as a separate group in the Wu-tai (Five Dynasties) period (907–960), when the old strongholds of aristocracy in the northeast and northwest became centres of bitter military and political struggles. The aristocratic clans that survived did so by merging into the new official-literati class; this class was based not

on birth alone but on education, office holding, and the possession of landed property.

At the same time there was a return to semiservile relationships at the base of the social pyramid. Sheer economic necessity led many peasants either to dispose of their lands and become tenants or hired labourers of rich neighbours or to become dependents of a powerful patron. Tenancy, which in early T'ang times had most often been a temporary and purely economic agreement, now developed into a semipermanent contract requiring some degree of personal subordination from the tenant.

The new provincial officials and local elites were able to establish their fortunes as local landowning gentry largely because after 763 the government ceased to enforce the system of state-supervised land allocation. In the aftermath of the An Lu-shan and later rebellions, large areas of land were abandoned by their cultivators; other areas of farmland were sold off on the dissolution of the monastic foundations in 843–846. The landed estate managed by a bailiff and cultivated by tenants, hired hands, or slaves became a widespread feature of rural life. Possession of such estates, previously limited to the established families of the aristocracy and the serving officials, now became common at less exalted levels.

Population movements. Censuses taken during the Sui and T'ang dynasties provide some evidence as to population changes. Surviving figures for 609 and for 742, representing two of the most complete of the earlier Chinese population registrations, give totals of some 9,000,000 households, or slightly more than 50,000,000 persons. Contemporary officials considered that only about 70 percent of the population was actually registered, so that the total population may have been as much as 70,000,000.

Between 609 and 742 a considerable redistribution of population took place. The population of Hopeh and Honan fell by almost a third because of the destruction suffered at the end of the Sui era and in the invasions of the 690s and because of epidemics and natural disasters. The population of Ho-tung (modern Shansi) and of Kuan-chung and Lung-yu (modern Shensi and Kansu) also fell, though not so dramatically. The population of the south, particularly the southeastern region around the lower Yangtze, took a leap upward, as did that of Szechwan.

Whereas under the Sui the population of the Great Plain (Hopeh and Honan) had accounted for more than half of the empire's total, by 742 this had dropped to 37 percent. The Huai–Yangtze area, which had contained only about 8 percent of the total in 609, now contained one-quarter of the entire population, and Szechwan's share jumped from 4 percent to 10 percent of the total, exceeding the population of the metropolitan province of Kuan-chung. The increase in the south was almost entirely concentrated in the lower Yangtze Valley and Delta and in Chekiang.

The southward migration

Although there are no reliable population figures from the late T'ang era, the general movement of population toward the south certainly continued; there were considerable increases in the population of the area south of the Yangtze, in modern Kiangsi and Hunan, and in Hupeh. The chaos of the last decades of the T'ang dynasty completed the ruin of the northwest. After the destruction of the city of Ch'ang-an in the Huang Ch'ao rebellion, no regime ever again established its capital in that region.

Growth of the economy. The 8th and 9th centuries were a period of growth and prosperity. The gradual movement of the population away from the north, with its harsh climate and dry farming, into the more fertile and productive south meant a great proportional increase in productivity. The south still had large areas of virgin land. Fukien, for example, was still only marginally settled along the coastline at the end of T'ang times. During the latter half of the T'ang, the Huai and lower Yangtze became a grain-surplus area, replacing Hopeh and Honan. From 763 to the mid-9th century, great quantities of grain were shipped from the south annually as tax revenue. New crops, such as sugar and tea, were grown widely. The productivity of the Yangtze Valley was increased by double-cropping land with rice and winter wheat and by developing new varieties of grain. Whereas in early T'ang times the chief silk-producing areas had been in the northeast, after the An Lu-shan rebellion silk production began to increase rapidly in Szechwan and the Yangtze Delta region.

Expansion of the grain crop

A boom in trade soon followed. The merchant class threw off its traditional legal restraints. In early T'ang times there had been only two great metropolitan markets, in Ch'ang-an and Lo-yang. Now every provincial capital became the centre of a large consumer population of officials and military, and the provincial courts provided a market for both staple foodstuffs and luxury manufactures. The diversification of markets was still more striking in the countryside. A network of small rural market towns, purely economic in function and acting as feeders to the county markets, grew up. At these periodic markets, held at regular intervals every few days, traveling merchants and peddlers dealt in the everyday needs of the rural population. By the end of the T'ang period these rural market centres had begun to form a new sort of urban centre, intermediate between the county town, with its administrative presence and its central market, and the villages.

The growth of trade brought an increasing use of money. In early T'ang times silk cloth had been commonly employed as money in large transactions. When the central government lost control of the major silk-producing region in Hopeh and Honan, silk was replaced in this use by silver. The government neither controlled silver production nor minted a silver coinage. Silver circulation and assay were in the hands of private individuals. Various credit and banking institutions began to emerge: silversmiths took money on deposit and arranged for transfers of funds; a complex system of credit transfers arose by which tea merchants would pay the tax quota for a district, sometimes even for a whole province, out of their profits from the sale of the crop at Ch'ang-an and receive reimbursement in their home province.

The increasing use of money and of silver also affected official finance and accounting. Taxes began to be assessed in money. The salt monopoly was collected and accounted for entirely in money. The government also began to look to trade as a source of revenue—to depend increasingly on taxes on commercial transactions, levies on merchants, transit taxes on merchandise, and sales taxes.

The merchants

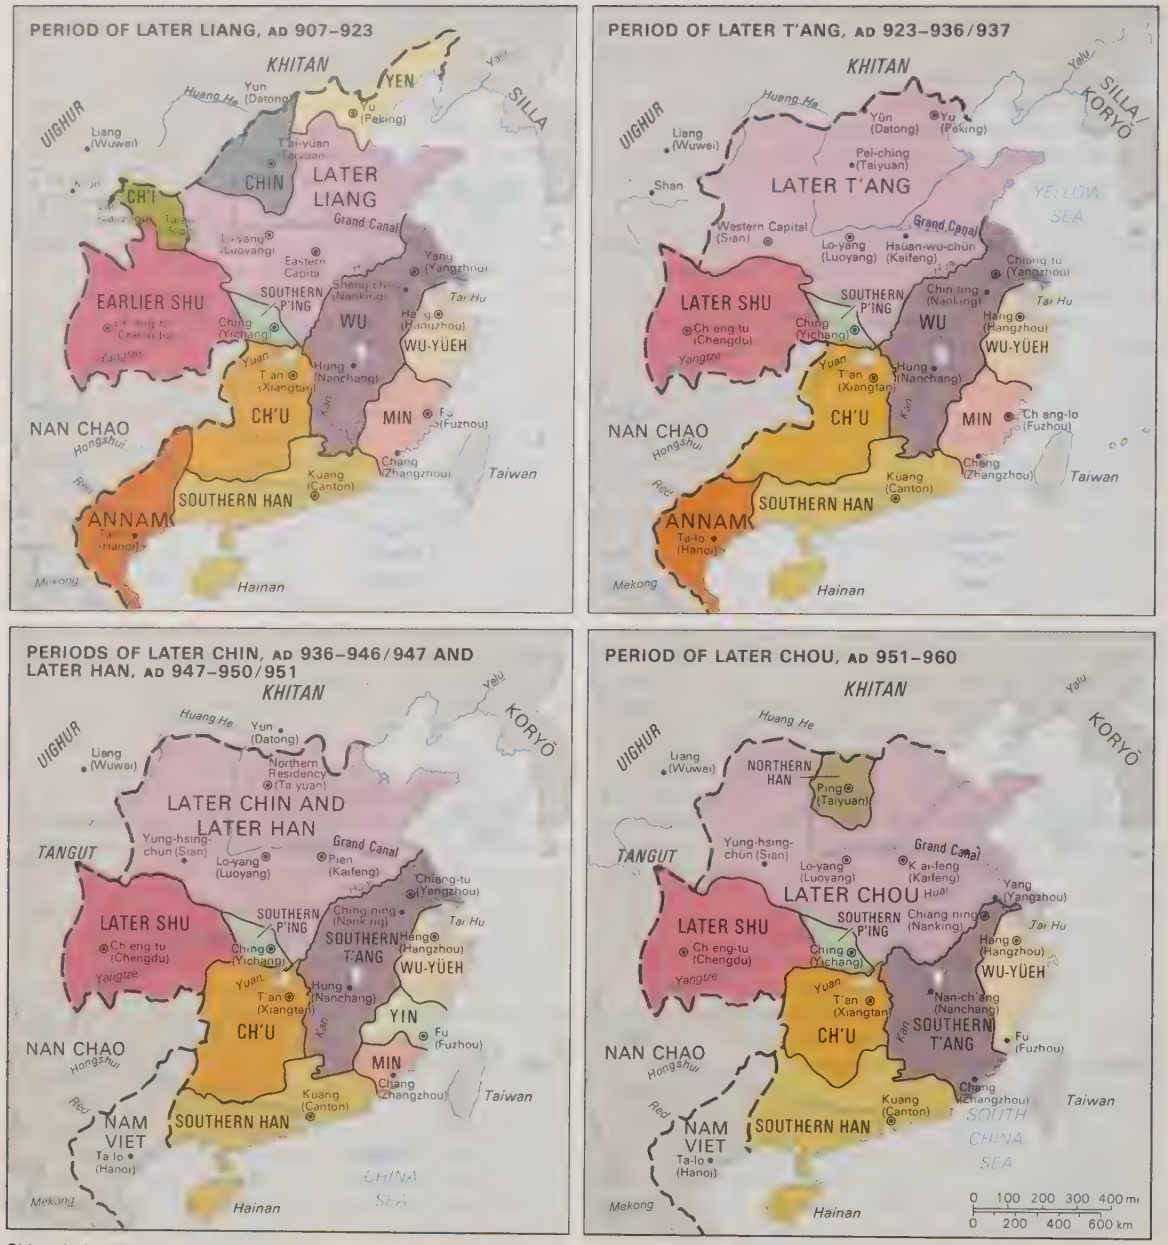
The most prosperous of the merchants were the great dealers in salt, the tea merchants from Kiangsi, the bankers of the great cities and particularly of Ch'ang-an, and the merchants engaged in overseas trade in the coastal ports. Foreign trade was still dominated by non-Chinese merchants. Yang-chou and Canton had large, Arab trading communities. The northern coastal traffic was dominated by the Koreans. Overland trade to Central Asia was mostly in the hands of Sogdian and later of Uighur merchants. Central Asian, Sogdian, and Persian merchants and peddlers carried on much local retail trade and provided restaurants, wine shops, and brothels in the great cities. Only in the 9th century did the foreign influence in trade begin to recede.

In the late T'ang many officials began to invest their money (and official funds entrusted to them) in commercial activities. High officials took to running oil presses and flour mills, dealing in real estate, and providing capital for merchants. The wall between the ruling class and the merchants that had existed since the Han period was rapidly breaking down in the 9th century, and the growth of urbanization, which characterized the Sung period (960–1279), had already begun on a wide scale. (D.C.T.)

The Five Dynasties and the Ten Kingdoms

The period of political disunity between the T'ang and the Sung lasted little more than half a century, from 907 to 960. During this brief era, when China was truly a multistate system, five short-lived regimes succeeded one another in control of the old Imperial heartland in northern China, hence the name Wu-tai (Five Dynasties). During these same years, 10 relatively stable regimes occupied sections of southern and western China, so the period is also referred to as that of the Shih-kuo (Ten Kingdoms).

Most of the major developments of this period were extensions of changes already under way during the late T'ang, and many were not completed until after the



China during the Five Dynasties and Ten Kingdoms period *c.* AD 907–960.

founding of the Sung dynasty. For example, the process of political disintegration had begun long before Chu Wen brought the T'ang dynasty to a formal end in 907. The developments that eventually led to reunification, the rapid economic and commercial growth of the period, and the decline of the aristocratic clans had also begun long before the first Sung ruler, T'ai-tsu, reconquered most of the empire, and they continued during the reigns of his successors on the Sung throne.

THE WU-TAI (FIVE DYNASTIES)

None of the Wu-tai regimes that dominated North China ever forgot the ideal of the unified empire. Each sought, with gradually increasing success, to strengthen the power of the central authorities. Even Chu Wen, who began the Wu-tai by deposing the last T'ang emperor in 907, sought to extend his control in the north. While consolidating his strength on the strategic plains along the Huang Ho (Yellow River) and connecting them with the vital transportation system of the Grand Canal, he made the significant choice of locating his base at Pien (modern K'ai-feng, in Honan); it later became the Pei (Northern) Sung capital. Pien's lack of historical prestige was balanced by the presence of the ancient capital, Lo-yang, a short distance to the west, which was still the nation's cultural centre. Chu Wen's short-lived Hou (Later) Liang dynasty, founded in 907, was superseded by the Hou T'ang in 923, by the Hou Chin in 936, by the Hou Han in 947, and by the Hou Chou in 951. These rapid successions of dynasties came to an end only with the rise in 960 of the Sung dynasty, which finally succeeded in establishing another lasting empire and in taking over much, though not all, of the former T'ang Empire.

Changes in the political process

Beneath the surface, however, were the continuous efforts of a reintegrative political process that heralded the coming of a new empire and helped to shape its political system. In this respect the successive rulers moved like a relay team along the tortuous road back to unification. These militarists expanded their personal power by recruiting peoples of relatively humble social origins to replace the aristocrats. Such recruits owed personal allegiance to their masters, on whose favours their political positions remained dependent, thus presaging the rise of absolutism.

Rather than being discarded, the T'ang administrative form underwent expedient alterations so that the new types of officials, promoted because of merit from regional posts to palace positions, could use the military administration to supervise the nearby provinces and gradually bring

them under direct control. Top priority went to securing fiscal resources from the salt monopoly, tribute transport, and in particular new tax revenues, without which military domination would have been hard to sustain and political expansion impossible. Eventually, a pattern of centralizing authority emerged. Fiscal and supply officials of the successive regimes went out to supervise provincial finances and the local administration. The minor militarists, heretofore the local governors in control of their own areas, were under double pressure to submit to reintegrative measures. They faced the inducement of political accommodation, which allowed them to keep their residual power, and the military threat of palace army units commanded by special commissioners, which were sent on patrol duty into their areas. The way was thus paved, in spite of occasional detours and temporary setbacks, for the ultimate unification.

The seemingly chaotic period was in fact less chaotic than other rebellious times, except from the standpoint of the aristocrats, who lost their preeminent status along with their large estates, which were usually taken over piecemeal by their former managers. The aristocratic era in Chinese history was gone forever; a new bureaucratic era was about to begin.

THE SHIH-KUO (TEN KINGDOMS)

From the time of the T'ang dynasty until the Ch'ing dynasty, which arose in the 17th century, China consisted of two parts: the north, militarily strong, and the south, economically and culturally wealthy. Between 907 and 960, 10 independent kingdoms emerged in China, mainly in the south: the Wu (902–937), the Nan (Southern) T'ang (937–975/976), the Nan P'ing (924/925–963), the Ch'u (927–951), the Ch'ien (Former) Shu (907–925), the Hou (Later) Shu (934–965), the Min (909–945/946), the Pei (Northern) Han (951–979), the Nan Han (917–971), and the Wu-Yüeh (907–978), the last located in China's most rapidly advancing area—in and near the lower Yangtze Delta.

Regional developments

Some of these separate regimes achieved relative internal stability; none attained enough strength to strive to unify China. Nonetheless, the regional developments in South China, in the upper Yangtze region in southwest China, and in the lower Yangtze region in southeast China were of great interest. In South China, the Min kingdom in modern Fukien and the Nan Han in modern Kwangtung and Kwangsi reflected sharp cultural differences. Along the coast, sea trade expanded, promoting both urban prosperity and cultural diversity. On land, wave after wave of refugees moved southward, settling along rivers and streams and in confining plains and mountain valleys, using a frontier agriculture but with highly developed irrigation and land reclamation. Usually they pushed aside the aboriginal minorities, earlier settlers, and previous immigrant groups. This process turned South China into a cultural chessboard of great complexity, with various subcultural pieces sandwiched between one another. Many eventually evolved along different lines.

In southwest China the valley of modern Szechwan presented an interestingly different picture of continuous growth. Usually protected from outside disturbances and invasions by the surrounding mountains, it enjoyed peace and prosperity except for one decade of instability between the Ch'ien Shu and Hou Shu. The beautiful landscape inspired poets who infused a refreshing vitality into old-style poetry and essays. In this region, a stronghold of Taoist religion, the people inserted into Confucian scholarship an admixture of Taoist philosophy. Buddhism also flourished. These intellectual trends in Szechwan foreshadowed an eclectic synthesis of the three major teachings—Confucianism, Taoism, and Buddhism.

The Buddhist monasteries owned large estates and were usually among the first to introduce new and better technology. Growing commerce created a demand for money. The ensuing shortage of copper was met by an increasing output of iron through more efficient methods and an elementary division of labour in production. When the limited number of copper coins could no longer meet the growing volume of trade, iron currency briefly went into circulation. Increasing commerce also resulted in the development of various paper credit instruments, the best known being drafts for transmitting funds called *fei-ch'ien* ("flying money"). Somewhat later the private assay shops in Szechwan began to issue certificates of deposit to merchants who had left valuables at the shops for safekeeping. These instruments, which began to circulate, were the direct ancestors of the paper money that emerged in the early 11th century.

During the Wu-tai printing became common. The most famous, and monumental, cultural production of the period was the editing and printing of the Confucian Classics and the Buddhist *Tipiṭaka,* but the period also saw the rise of a printing industry that produced works for private buyers. The best printing in the country during the Wu-tai and the Sung dynasty came from the regions of Szechwan and Fukien.

Leadership of the Yangtze Delta

From the Wu-tai onward southeast China, especially its core region of the Yangtze Delta, began to lead the country in both economic prosperity and cultural refinement. In this region fertile soil, irrigation networks, and highly selective crops combined to create the best model of intensive farming. Interlocking streams, rivers, and lakes fed an ever-increasing number of markets, market towns, cities, and metropolitan areas, where many farm products were processed into an ever-expanding variety of consumer goods. Such development enhanced regional trade, stimulated other regions to adopt specialization, and promoted overseas commerce.

The Sung conquerors from the north recognized the high level of cultural development in this region. After the surrender of the last Nan T'ang ruler, himself a renowned poet, the unexcelled royal library in the capital at Nanking was moved to the north; along with it went many officials who were skilled in art, literature, and bibliography. The surrender of the Wu-Yüeh kingdom, slightly farther south, followed the same pattern. Moreover, refined culture developed away from the coast in such inland mountainous areas as modern Kiangsi, which shortly thereafter produced internationally coveted porcelain and where many great artists and scholar-officials attained positions of cultural leadership. Thereafter, southeast China retained its cultural excellence. At the end of the Pei Sung period the Nan Sung based itself in the lower Yangtze Delta and located its capital at Hang-chou, the former capital of the Wu-Yüeh.

As traditional histories stress, this period of disunity definitely had its dark side: militarism, wars, disintegration of the old order, and an inevitable lowering of moral standards. The dark side, however, stemmed largely from underlying changes that were transforming China into a new pattern that would last for nearly a millennium.

The "barbarians": Tangut, Khitan, and Juchen

On the frontier the far-reaching influence of T'ang culture affected various nomadic, seminomadic, and pastoral peoples.

THE TANGUT

In the northwest the Tangut, a Tibetan people, inhabited the region between the far end of the Great Wall in modern Kansu and the Huang Ho bend in Inner Mongolia. Their semioasis economy combined irrigated agriculture with pastoralism. Their control over the terminus of the famous Silk Road made them middlemen in trade between Central Asia and China. They adopted Buddhism as a state religion, in government and education followed the T'ang model, and devised a written script for their own language. This richly mixed culture blossomed, as evidenced by the storing at the Tun-huang caves of an unparalleled collection of more than 30,000 religious paintings, manuscripts, and books in Chinese, Tibetan, Uighur, and other languages. In 1038 the Tangut proclaimed their own kingdom of Hsi Hsia, which survived for nearly two centuries with remarkable stability despite a series of on-and-off border clashes with the neighbouring states in North China. The kingdom's end came with the Mongols, the first nomads to conquer all of China.

THE KHITAN

To the north at the time of the Wu-tai rose the seminomadic but largely pastoral Khitan, who were related to the eastern Mongols. The word Khitan (or Khitai) is the source of Cathay, the name for North China in medieval Europe (as reported by Marco Polo), and of Kitai, the Russian name for China. The Khitan founded the Liao Empire (907–1125) by expanding from the border of Mongolia into both southern Manchuria and the 16 prefectures below the Great Wall. This area south of the line of the Great Wall was to remain out of Chinese political control for more than 400 years. Its control by a non-Chinese state posed a dangerous security problem for the Pei Sung. More importantly in the long run, this region acted for centuries as a centre for the mutual exchange of culture between the Chinese and the northern peoples.

The Liao made Yen-ching (modern Peking) their southern capital, thus starting that city's history as a capital, and claimed to be the legitimate successors to the T'ang. They incorporated their own tribes under respective chieftains and, with other subdued tribes in the area, formed a confederation, which they transformed into a hereditary monarchy. Leadership always remained in the hands of the ruling tribe, the Yeh-lü, who for the sake of stability shifted to the Chinese clan system of orderly succession.

The Liao economy was based on horse and sheep raising and on agriculture. Millet was the main crop, and salt, controlled by government monopoly, was an important source of revenue. There were also such other riches as iron produced by smelters. The Liao employed an effective dual system of administration to guard against the danger of being absorbed by Sinicization. They had one administration for their own people that enforced tribal laws, maintained traditional rites, and largely retained the steppe style of food and clothing. The Liao deliberately avoided the use of Chinese and added to their particular branch of the Mongolian language two types of writing—a smaller one that was alphabetical and a larger one related to Chinese characters. A second administration governed the farming region by the old T'ang system, using T'ang official titles, an examination system, Chinese-style tax regulations, and the Chinese language. The laws of the second administration enforced the established way of life, including such practices as ancestral worship among the Chinese subjects. The status of Chinese subjects varied. Some were free subjects who might move upward into the civil service; others might be held in bondage and slavery.

Dual system of administration

Though honouring the Confucian philosophy, the Liao rulers patronized Chinese Buddhism. Their achievements were generally military and administrative rather than cultural, but they did provide a model for their successors, the Chin, who in turn influenced the Mongols and, through them, succeeding Chinese dynasties.

THE JUCHEN

The Liao were eventually overthrown by the Juchen (Ju-chen in Wade–Giles, Ruzhen in Pinyin), another seminomadic and semipastoral people who originated in Manchuria, swept across North China, ended the Pei Sung, and established the Chin dynasty (1115–1234). This new and much larger empire in North China followed the Liao pattern of dual government and of some acculturation but at a much higher cultural level.

The Juchen, in establishing their Chinese-style Chin Empire, occupied a broader geographic region in the farming country than had any previous nomadic or pastoral conquerors. The migration of their own people in large numbers notwithstanding, they were proportionally a smaller minority than were the Khitan, for the Chin ruled a much larger Chinese population. Because they formed a small minority in their own empire, their tribesmen were kept in a standing army that was always prepared for warfare. Though quartered among their farming subjects, they were expected to respond to the command of their captains at short notice. In the military service the Juchen language was kept alive, and no Chinese-style names, clothing, or customs were permitted. They realized that protecting their separate ethnic and cultural identity was indispensable to maintaining military superiority.

Politically, however, it was necessary for the Juchen rulers to familiarize themselves with the higher culture of their Chinese subjects in order to manage state affairs. While limiting Chinese participation in the government, they shrewdly deflected the interests of their subjects toward the pursuit of such peaceful arts as printing, scholarship, painting, literature, and, significantly, the development of drama for widespread entertainment. (These trends continued under the Mongols and enriched the Chinese culture.) In spite of the Juchen efforts, time was on the side of the majority culture, which gradually absorbed the minority. The transplanted tribesmen, after settling on farmland, could not avoid being affected by the Chinese way of life, particularly during long periods of peace.

Juchen assimilation

Economically, the Juchen were no match for the Chinese. In time a number of Juchen became tenants on Chinese-owned land; some were reduced to paupers. Their economic decline altered social relations. Eventually they were permitted intermarriage, usually with parties wealthier than themselves. Their military strength also declined. It became normal for military units to be undermanned. Captains of "hundreds" often could put no more than 25 men into the field, and captains of "thousands" had no more than four or five such nominal "hundreds" under them. Their ruling class followed a parallel decline. The interests of the ruling group shifted from government affairs to Confucian studies, Chinese Classics, and T'ang- and Sung-style poetry. The rulers found little use for the two styles of Juchen script that their ancestors had devised.

Eventually the Juchen, much weakened, were brought down by the Mongols, led by Genghis Khan and his successors. (See below *The Yüan, or Mongol, dynasty: The Mongol conquest of China.*)

The Sung dynasty

PEI (NORTHERN) SUNG (960–1127)

The Pei Sung (also known simply as the Sung) was the last major Chinese dynasty to be founded by a coup d'état. Its founder, Chao K'uang-yin (known by his temple name, T'ai-tsu), the commander of the capital area of K'ai-feng and inspector general of the Imperial forces, usurped the throne from the Hou Chou, the last of the Wu-tai.

Unification. Though a militarist himself, T'ai-tsu ended militarism as well as usurpation. Even his own coup was skillfully disguised to make it appear that the popular acclaim of the rank and file left him with no choice. Masterful in political maneuvering, T'ai-tsu, as emperor (reigned 960–976), did not destroy other powerful generals as had many previous founding rulers. Instead, he persuaded them to give up their commands in exchange for honorary titles, sinecure offices, and generous pensions—an unheard-of arrangement in Chinese history. The Sung founder and his successors reduced the military power of the generals and used a variety of techniques to keep them weak, but Sung rulers continued to support their social importance by frequently marrying members of the Imperial clan to members of leading military families.

End of militarism and of usurpation

With a shrewd appreciation of the war-weariness among the population, T'ai-tsu stressed the Confucian spirit of humane administration and the reunification of the whole country. To implement this policy, he took power from the military governors, consolidated it at court, and delegated the supervision of military affairs to able civilians; but no official was regarded as above suspicion. A pragmatic civil service system evolved, with a flexible distribution of power and elaborate checks and balances. Each official had a titular office, indicating his rank but not his actual function, a commission for his normal duties, and additional assignments or honours. This seemingly confusing formula enabled the ruler to remove an official to a lower position without demotion of rank, to give an official a promotion in rank but an insignificant assignment, or to pick up a low-ranking talent and test him on a crucial commission. Councillors controlled only the civil administration because the division of authority made the military commissioner and the finance commissioner separate entities, reporting directly to the ruler, who coordinated all important decisions. In decision making, the Emperor

received additional advice from academicians and other advisers—collectively known as opinion officials—whose function was to provide separate channels of information and to check up on the administrative branches.

Similar checks and balances existed in the diffused network of regional officials. The empire was divided into circuits, which were units of supervision rather than administration. Within these circuits officials, or intendants, were charged with overseeing the civil administration. Below these intendants were the actual administrators. These included prefects, whose positions were divided into several grades according to an area's size and importance. Below the prefects there were district magistrates (also called subprefects), in charge of areas corresponding roughly in size to counties. The duties of these subprefects were catholic, for they were supposed to see to all aspects of the welfare of the people in their area. This was the lowest level of major direct Imperial rule (though there were some petty officials on levels below the district). Because the members of the formal civil service level of the government were so few, actual administration in the yamen, or administrative headquarters, depended heavily on the clerical staff. Beyond the yamen walls control was in the hands of an officially sanctioned but locally staffed sub-bureaucracy.

Following Confucian ideals, the founder of the Sung dynasty lived modestly, listened to his ministers, and curbed excessive taxation. The rising prestige of his regime preceded his conquests. He also absorbed the best military units under his own command and disciplined them in the same Confucian style. His superior force notwithstanding, he embarked upon a reunification program by mixing war with lenient diplomatic or accommodative terms that assured defeated rivals of generous treatment. A well-planned strategy first took Szechwan in the southwest in 965, the extreme south in 971, and the most prosperous lower Yangtze area in the southeast one year before his death, making the reunification nearly complete. The Wu-Yüeh, the sole survivor among the Shih-kuo (Ten Kingdoms), chose to surrender without a war in 978.

The sudden death of the founder of the Sung dynasty left a speculative legend of assassination, though it was probably caused by his heavy drinking. The legend stemmed from the fact that his young son was denied the orderly succession. Instead, the Emperor's younger brother, who had acquired much experience at his side, seized the throne. With reunification accomplished in the south, the new emperor, T'ai-tsung (reigned 976–997/998), turned northward to fight the Khitan Empire, only to suffer a disastrous defeat (986). A relative shortage of horses and grazing grounds to breed them, in contrast to the strong Khitan cavalries, was not the only reason for the defeat. It also resulted from a deliberate policy of removing generals from their armies, subordinating officers to civilians, concentrating strength in Imperial units, and converting most provincial armies into labour batallions.

Defeat by the Khitan Empire

The Sung never achieved a military prowess comparable to that of the Han or the T'ang. Despite the occasional bellicosity of its officials, the Sung government failed to penetrate Indochina or to break the power of the Hsi Hsia of Tibet. As a result, Sung China became increasingly isolated, especially from Central Asia, whence much cultural stimulus had come under preceding dynasties. Combined with a natural pride in internal advancements, China's cultural ethnocentrism deepened.

Consolidation. Under the third emperor, Chen-tsung (reigned 997/998–1022/23), the Sung achieved consolidation. A threatening Khitan offensive was directly met by the Emperor himself. A few battles assured neither side of victory. The two empires pledged peaceful coexistence in 1004 through an exchange of sworn documents that foreshadowed modern international treaties. The Khitan gave up its claim to a disputed area it had once occupied below the Great Wall, and the Sung agreed to a yearly tribute: 100,000 units (a rough equivalent of ounces) of silver and 200,000 rolls of silk. It was a modest price for the Sung to pay for securing the frontier.

The Emperor thereafter sought to strengthen his absolutist image by claiming a Taoist charisma. Prompted by magicians and ingratiating high officials, he proclaimed that he had received a sacred document directly from Heaven. He ordered a grand celebration with elaborate rites, accompanied by reconstructed music of ancient times; and he made a tour to offer sacrifices at Mt. T'ai, following a Han dynasty precedent.

After the Emperor's death, friction arose between his widow, the empress dowager, who was acting as regent, and Jen-tsung (reigned 1022/23–1063/64), his teenage son by a palace lady of humble rank. Following the death of the Empress Dowager, the Emperor divorced his empress, who had been chosen for him by and had remained in sympathy with the Empress Dowager. The divorce was unjustifiable in Confucian morality and damaged the Imperial image.

By this time the bureaucracy was more highly developed and sophisticated than that of the early Sung. Well-regulated civil service examinations brought new groups of excellent scholar-officials who, though a numerical minority, dominated the higher policy-making levels of government. The sponsorship system, which discouraged favouritism by putting responsibility upon the sponsors for the official conduct of their appointees, also ensured deserving promotions and carefully chosen appointments. Many first-rate officials—especially those from the south whose families had no previous bureaucratic background—upheld Confucian ideals. These new officials were critical not only of palace impropriety but also of bureaucratic malpractices, administrative sluggishness, fiscal abuses, and socioeconomic inequities. Respecting absolutism, they focused their attacks upon a veteran chief councillor, whom the Emperor had trusted for years. Factionalism developed because many established scholar-officials, mostly from the north, with long bureaucratic family backgrounds, stood by their leader, the same chief councillor.

Growth of the bureaucracy

A series of crises proved the complaints of the idealists justified. After half a century of complacency, peace and prosperity began to erode. This became apparent in the occurrence of small-scale rebellions near the capital itself; in the disturbing inability of local governors to restore order themselves; and in a dangerous penetration of the northwestern border by Hsi Hsia, which rejected its vassal status and declared itself an independent kingdom. The Khitan took advantage of the changing military balance by threatening another invasion. The idealistic faction, put into power under these critical circumstances in 1043–44, effectively stopped the Hsi Hsia on the frontier by reinforcing a chain of defense posts and made it pay due respect to the Sung as the superior empire (though the Sung no longer claimed suzerainty). Meanwhile, the peace with Khitan was reensured by an increase in yearly tribute.

The court also instituted administrative reforms, stressing the need for emphasizing statecraft problems in civil service examinations, eliminating patronage appointments for family members and relatives of high officials, and enforcing strict evaluation of administrative performance. It also advocated reduction of compulsory labour, land reclamation and irrigation construction, organization of local militias, and a thorough revision of codes and regulations. Though mild in nature, the reforms hurt vested interests. Shrewd opponents undermined the reformers by misleading the Emperor into suspecting that they had received too much power and were disrespectful of him personally. With the crises eased, the Emperor found one excuse after another to send most reformers away from court. The more conventionally minded officials were returned to power.

Despite a surface of seeming stability, the administrative machinery once again fell victim to creeping deterioration. When some reformers eventually returned to court, beginning in the 1050s, their idealism was modified by the political lesson they had learned. Eschewing policy changes and tolerating colleagues of varying opinions, they made appreciable progress by concentrating upon the choice of better personnel, proper direction, and careful implementation within the conventional system; but many fundamental problems remained unsolved. Mounting military expenditures did not bring greater effectiveness; an expanding and more costly bureaucracy could not reverse

Creeping deterioration of the administration

the trend of declining tax yields. Income no longer covered expenditures. During the brief reign of Ying-tsung (1063/64–1067/68), relatively minor disputes and symbolically important issues concerning ceremonial matters embroiled the bureaucracy in mutual and bitter criticism.

Reforms. Shen-tsung (reigned 1067/68–1085/86) was a reform emperor. Originally a prince reared outside the palace, familiar with social conditions and devoted to serious studies, he did not come into the line of Imperial succession until adoption had put his father on the throne before him. Shen-tsung responded vigorously (and rather unexpectedly, from the standpoint of many bureaucrats) to the problems troubling the established order, some of which were approaching crisis proportions. Keeping above partisan politics, he made the scholar-poet Wang An-shih his chief councillor and gave him full backing to make sweeping reforms. Known as the new laws, or new policies, these reform measures attempted drastic institutional changes. In sum, they sought administrative effectiveness, fiscal surplus, and military strength. Wang's famous "Ten Thousand Word Memorial" outlined the philosophy of the reforms. Contrary to conventional Confucian views, it upheld assertive governmental roles; but its ideal remained basically Confucian—economic prosperity would provide the social environment essential to moral well-being.

Economic gains from the reforms

Never before had the government undertaken so many economic activities. The Emperor empowered Wang to institute a top-level office for fiscal planning, which supervised the Commission of Finance, previously beyond the jurisdiction of the chief councillor. The government squarely faced the reality of a rapidly spreading money economy by increasing the supply of currency. The state became involved in trading, buying specific products of one area for resale elsewhere (thereby facilitating the exchange of goods), stabilizing prices whenever and wherever necessary, and making a profit itself. This did not displace private trading activities. On the contrary, the government extended loans to small urban and regional traders through state pawnshops—a practice somewhat like modern government banking but unheard-of at the time. Far more important, if not controversial, the government made loans at the interest rate, low for the period, of 20 percent to the whole peasantry during the sowing season, thus assuring their farming productivity and undercutting their dependency upon usurious loans from the well-to-do. The government also maintained granaries in various cities to ensure adequate supplies on hand in case of emergency need. The burden upon rich and poor alike was made more equitable by a graduated tax scale based upon a reassessment of the size and the productivity of the landholdings. Similarly, compulsory labour was converted to a system of graduated tax payments, which were used to finance a hired-labour service program that at least theoretically controlled underemployment in farming areas. Requisition of various supplies from guilds was also replaced by cash assessments, with which the government was to buy what it needed at a fair price.

Wang's reforms achieved increased military power as well. To remedy the Sung's military weakness and to reduce the immense cost of a standing professional army, the villages were given the duty of organizing militias, under the old name of *pao-chia,* to maintain local order in peacetime and to serve as army reserves in wartime. To reinforce the cavalry, the government procured horses and assigned them to peasant households in northern and northwestern areas, in consideration for which one member of the family had the privilege of serving in the army with his horse. Various weapons were also developed. As a result of these efforts, the empire eventually scored some minor victories along the northwestern border.

The gigantic reform program required an energetic bureaucracy, which Wang attempted to create—with mixed results—by means of a variety of policies: promotion of a nationwide state school system; establishment or expansion of specialized training in such utilitarian professions as the military, law, and medicine, which were neglected by Confucian education; placing a strong emphasis on supportive interpretations of Classics, some of which Wang himself supplied rather dogmatically; demotion and dismissal of dissenting officials (thus creating conflicts in the bureaucracy); and provision of strong incentives for better performances by clerical staffs, including merit promotion into bureaucratic ranks.

Opposition to the reforms

The magnitude of the reform program was matched only by the bitter opposition to it. Determined criticism came from the groups hurt by the reform measures: large landowners, big merchants, and moneylenders. Noncooperation and sabotage arose among the bulk of the bureaucrats, drawn as they were from the landowning and otherwise wealthy classes. Geographically, the strongest opposition came from the traditionally more conservative northern areas. Ideologically, however, the criticisms did not necessarily coincide with either class background or geographic factors. They were best expressed by many leading scholar-officials, some of whom were northern conservatives while others were brilliant talents from Szechwan. Both the Emperor and Wang failed to reckon with the fact that, by its very nature, the entrenched bureaucracy could tolerate no sudden change in the system to which it had become accustomed. It also reacted against the overconcentration of power at the top, which neglected the art of distributing and balancing power among government offices; against the overexpansion of governmental power in society; and against the tendency to apply policies relatively uniformly in a locally diverse empire.

Without directly attacking the Emperor, the critics attacked the reformers for deviations from orthodox Confucianism. It was wrong, the opponents argued, for the state to pursue profits, to assume inordinate power, and to interfere in the normal life of the common people. It was often true as charged that the reforms—and the resulting changes in government—brought about the rise of unscrupulous officials, an increase in high-handed abuses in the name of strict law enforcement, unjustified discrimination against many scholar-officials of long experience, intense factionalism, and resulting widespread miseries among the population—all of which were in contradiction to the claims of the reform objectives. Particularly open to criticism was the rigidity of the reform system, which allowed little regional discretion or desirable adjustment for differing conditions in various parts of the empire.

Effects of the reforms

In essence the reforms augmented growing trends toward both absolutism and bureaucracy. Even in the short run, the cost of the divisive factionalism that the reforms generated had disastrous effects. To be fair, Wang was to blame for his overzealous if not doctrinaire beliefs, his low tolerance for criticism, and his persistent support of his followers even when their errors were hardly in doubt. Nonetheless, it was the Emperor himself who was ultimately responsible. Determined to have the reform measures implemented, he ignored loud remonstrances, disregarded friendly appeals to have certain measures modified, and continued the reforms after Wang's retirement.

The traditional historians, by studying documentary evidence alone, overlooked the fact that scholar-officials rarely openly criticized an absolutist emperor, and they generally echoed the critical views of the conservatives in assigning the blame to Wang—a revisionist Confucian in public, a profound Buddhist practitioner in his old age, and a great poet and essayist.

Decline and fall. Careful balancing of powers in the bureaucracy, through which the rulers acted and from which they received advice and information, was essential to good government in China. The demonstrated success of this principle in early Pei Sung so impressed later scholars that they described it as the art of government. It became a lost art under Shen-tsung, however, in the reform zeal and more so in the subsequent eagerness to do away with the reforms.

Anti-reform period

The reign of Che-tsung (1085/86–1100) began with a regency under another empress dowager, who recalled the conservatives to power. An antireform period lasted until 1093, during which time most of the reforms were rescinded or drastically revised. Though men of integrity, the conservatives offered few constructive alternatives. They achieved a relaxation of tension and a seeming stability but did not prevent old problems from recurring. Some conservatives objected to turning back the clock, especially by

swinging to the opposite extreme, but they were silenced. Once the young emperor took control, he undid what the Empress Dowager had done; the pendulum swung once again to a restoration of the reforms, a period that lasted to the end of the Pei Sung. In such repeated convulsions, the government could not escape dislocation, and the society became demoralized. Moreover, the restored reform movement was a mere ghost without its original idealism. Enough grounds were found by conservatives out of power to blame the reforms for the fall of the dynasty.

Che-tsung's successor, Hui-tsung (reigned 1100–1125/26), was a great patron of the arts and an excellent artist himself, but such qualities did not make him a good ruler. Indulgent in pleasures and irresponsible in state affairs, he misplaced his trust in favourites. Those in power knew how to manipulate the regulatory system to obtain excessive tax revenues. At first the complacent emperor granted more support to government schools everywhere; the objection that this move might flood the already crowded bureaucracy was dismissed, seeing the significant gains it would bring in popular support among scholar-officials. Then the Emperor built a costly new Imperial garden. When his extravagant expenditures put the treasury in deficit, he rescinded scholarships in government schools. Support for him among scholar-officials soon vanished.

More serious was carelessness in war and diplomacy. The Sung disregarded the treaty and coexistence with the Liao Empire, allied itself with the expanding Juchen from Manchuria, and made a concerted attack on the Liao. The Sung commander, contrary to long-held prohibition, was a favoured eunuch; under him and other unworthy generals, military expenditures ran high, but army morale was low. The fall of Liao was cause for court celebration. But because the Juchen had done most of the fighting, they accused the Sung of not doing its share and denied it certain spoils of the conquest. The Juchen soon turned upon the Sung. At this point the Emperor chose to abdicate, giving himself the title of Taoist "emperor emeritus" and leaving affairs largely in the unprepared hands of his son, Ch'in-tsung (reigned 1125/26–1127), while seeking safety and pleasure himself by touring the Yangtze region.

Alliance with the Juchen

During this period the government became increasingly ineffective. The reform movement had enlarged both the size and duties of the clerical staff. The antireform period brought a cutback but also a confusion that presented manipulative opportunities to some clerks. Supervision was difficult because officials stayed only a few years, whereas clerks remained in office for long periods. Bureaucratic laxity spread quickly to the clerical level. Bribes for appointments went either to them or through their hands. It was they who made cheating possible at examinations, using literary agents as intermediaries between candidates and themselves.

The Juchen swept across the Huang Ho plain and found the internally decayed Sung an easy prey. During their long siege of K'ai-feng (1126) they repeatedly demanded ransoms in gold, silver, jewels, other valuables, and general supplies. The court, whose emergency call for help brought only undermanned reinforcements and untrained volunteers, met the invaders' demands and ordered the capital residents to follow suit. Finally, an impoverished mob plundered the infamous Imperial garden for firewood. The court remained convinced that financial power could buy peace, and the Juchen lifted the siege briefly. But once aware that local resources were exhausted and that the regime, even with the return of the Emperor Emeritus, no longer had the capability of delivering additional wealth from other parts of the country, the invaders changed their tactics. They captured the two emperors and the entire Imperial house, exiled them to Manchuria, and put a tragic end to the Pei Sung.

End of the Pei Sung

NAN (SOUTHERN) SUNG (1127–1279)

The Juchen could not extend their conquest beyond the Yangtze River. The Huai River valley, with its winding streams and crisscrossed marshlands, made cavalry operations difficult. Though the invaders penetrated this region and raided several areas below the Yangtze, they found the weather there too warm and humid for them. Moreover, the farther they went, the stronger the resistance they met. These areas had been leading the country in productivity and population and therefore in defense capability. Besides, the Juchen felt concerned about the areas in the rear that they had already occupied, where one after another of their puppet rulers had failed to secure popular support and the Juchen had been forced to consolidate control by setting up their own administration, following the Liao model of dual government.

Survival and consolidation. Despite the fall of the Pei Sung, the majority of scholar-officials refused to identify themselves with the alien conquerors. The same was generally true at the grass-roots level, among numerous roving bands of former volunteer militias, army units that had disintegrated, and bandits who had arisen during the disorder. As time went on, both civilians and military men turned toward the pretender to the throne, Kao-tsung. He was the only son of the former emperor Hui-tsung who had been absent from K'ai-feng and thus spared captivity.

As the founder of the Nan Sung, Kao-tsung devoted his long reign (1127–1162/63) to the arduous task of putting the pieces together. He rediscovered the lost arts of his ancestors: recruiting bureaucrats, securing fiscal resources, and extending centralized control. Since he started with no more than a few thousand troops, he had to place a much greater reliance on sophisticated politics, which he often artfully disguised. By praising the old, established ways of his predecessors, he pleased the conservatives who remained opposed to the reform system. In reality he modified the system he had inherited where it had obviously failed and pragmatically retained the parts that were working. Though he honoured the scholar-officials who had refused to serve under the puppet rulers, he was also glad to have those who had compromised their integrity in so serving. While he denounced the notorious favourites who had misled his father, he used the excuse of being broad-minded in picking many of their former subordinates for key positions, especially those experienced in raising tax revenues. A new network of officials called the fiscal superintendent generals was set up in each region, but they reported directly to court. Urban taxes were increased; they were easier to collect than rural revenues, and prosperous cities did not suffer much from the imposition. The high priority placed on fiscal matters, though not publicized as in the previous reform period in order to avoid a bad image, persisted throughout the Nan Sung, which was a long era of heavy taxation.

Use of sophisticated politics

Some officials, anxious for the recovery of the central plains, wished to have the capital located in Nanking, or farther up the Yangtze in central China. Kao-tsung discreetly declined such advice because these locations were militarily exposed. Instead, he chose Hang (present-day Hang-chou), renaming it Lin-an ("Temporary Safety"). Protected by the coastline and by the mountain ranges at its back, it was a securer retreat. It was popularly referred to as the place of Imperial headquarters (Hsing-tsai), later known to Marco Polo as Quinsai. Economically, it had the advantage of being at the corner of the lower Yangtze delta, the wealthy core of the new empire.

The Nan Sung, through continuous development, eventually became wealthier than the Pei Sung had been. Though its capital was near the sea—the only such case among Chinese empires—and international trade increased, the country was not sea-oriented. Kao-tsung maintained a defensive posture against periodic Juchen incursions from the north and meanwhile proceeded to restore Imperial authority in the hinterland as far west as the strategic Szechwan and in parts of Shensi to its immediate north.

No less important was the need for adequate military forces. Neither conscription nor recruitment would suffice. Because his position was militarily weak but financially strong, Kao-tsung adopted the *chao-an* policy, which offered peace to the various roving bands. The government granted them legitimate status as regular troops, and it overlooked their minor abuses in local matters. Thus, the size of Imperial forces swelled, and the problem of internal security was largely settled. The court then turned its attention to the control of these armies, which was inseparable from the issue of war or peace with the Juchen.

Quest for peace and security

Kao-tsung did not want to prolong the war; he valued most the security of his realm. A few minor victories did not convince him that he could hope to recover North China. Rather, he saw war as a heavy drain on available resources, with the risk of eventual defeat. Nor did he feel comfortable with the leading generals, on whom he would have to rely in case the war went on. He had to get around the critics at court, however, who found the Juchen peace terms humiliating and unacceptable: in addition to an enormous yearly tribute, the Juchen demanded that the Nan Sung formally admit, with due ceremonials, its inferior status as a vassal state. The shrewd emperor found an impeccable excuse for accepting the terms by claiming filial piety; he sought the return of his mother from captivity. To this, no Confucian could openly object. Significantly, Kao-tsung refrained from asking the release of former emperor Ch'in-tsung; such a move would have called into question the legitimacy of his succession.

A dramatic crisis occurred in 1141. On the eve of concluding peace negotiations, Kao-tsung decided to strip the three leading generals of their commands. The generals, summoned to the capital on the pretext of rewarding their merits, were promoted to military commissioners, while their units were reorganized into separate entities directly under Imperial control. Two of the generals reconciled themselves to the nominal honours and sizable pensions, but the third, Yüeh Fei, openly criticized the peace negotiations. He was put to death on a trumped-up charge of high treason. He later became the subject of a great legend, in which he was seen as a symbol of patriotism. At the time, however, his elimination signified full internal and external security for the court.

Relations with the Juchen. In spite of Kao-tsung's personal inclination, his artful guiding hand, and the success of his efforts to consolidate the empire, the impulse remained strong among many idealistic Confucians to attempt to recover the central plains. Even when silenced, they were potentially critical of court policies. Kao-tsung eventually decided to abdicate. He left the matter to his adopted heir, but he retained control from behind the throne. The new emperor, Hsiao-tsung (reigned 1162/63–1189/90), sympathetic to the idealists, appointed several of them to court positions and command posts. Information about a Juchen palace coup and alleged unrest in the Juchen Empire, particularly in the parts recently occupied, led to a decision to resume the war. An initial Sung attack was repulsed with such heavy losses that even regrouping took some time to accomplish. Sporadic fighting went on for nearly two years in the Huai Valley, reflecting a military stalemate. This resulted in a significant change in the new peace formula of 1165. The vassal state designation was dropped, and the Nan Sung attained a nearly equal footing with the Juchen, although it had to defer to the latter empire as the senior one.

Resumption of war

After the death of Kao-tsung in 1187, Hsiao-tsung followed the precedent of abdication. The international peace was kept during the brief reign of his son, Kuang-tsung (reigned 1189/90–1194/95), but it was broken again in 1205, during the reign of his grandson, Ning-tsung (reigned 1194/95–1224/25). The 40-year span of continuous peace dimmed the memory of difficulties in waging war. A new generation, nurtured by a flourishing Confucian education, tended to underestimate enemy strength and to think once more about recovering the central plains. The Nan Sung again initiated a northward campaign, and again it met with defeat. The event left no doubt that the Juchen Empire's hold over North China was far beyond the military capability of the southern empire alone. It was also obvious that the Chinese population in North China consisted of new generations brought up under alien domination and accustomed to it.

The Juchen not only retained their military edge over the Nan Sung but also revived their ambition of southward expansion. An offer was made to the governor of Szechwan, who decided to turn against the Sung court in faraway Lin-an and to become king of a vassal state allied with the Juchen. The civilian officials around him, however, took quick action and ended his separatist rebellion. Though a passing danger, it highlighted the fact that the Nan Sung consolidation was not entirely secure; peace was preferred.

The court's relations with the bureaucracy. Kao-tsung set the style for all subsequent Nan Sung emperors. The first two emperors in the Pei Sung, both strong militarists, had towered above the relatively modest bureaucracy they had created; most of their successors had found little difficulty in maintaining a balance in the bureaucracy. The circumstances under which the Nan Sung came into being, however, were quite different. Kao-tsung faced tough competition in building up a loyal bureaucracy, first with the two puppet rulers in the North and then from the dual administration the Juchen Empire had set up. He became keenly aware that a cautious handling of bureaucrats was essential. Later, the attempted rebellion in Szechwan taught his successors the same lesson.

Kao-tsung's handling of bureaucrats

Kao-tsung was an attentive student of history who consciously emulated the restoration by the Tung (Eastern) Han (AD 25–220) and defined his style as the "gentle approach." This meant using bureaucratic tactics to deal with the bureaucrats themselves. The gentle approach proved helpful in maintaining a balance at court and thus protecting councillors and Imperial favourites from the criticism of "opinion-officials." Absolutism had grown since the middle of the Pei Sung; the emperors had delegated much more power than before to a few ranking councillors. Similarly, Imperial favourites—*e.g.,* eunuchs, other personal attendants of the emperor, and relatives of the consorts—gained influence.

The opinion-officials by virtue of their rank or conviction wished to speak against those who abused power and influence; as a result of the factionalism that had plagued the late Pei Sung, their effectiveness had declined and never recovered. But as long as absolutism was qualified by Confucian values and the monarch cherished a Confucian image, he had to learn to deal with some adverse opinions; he often resorted to sophisticated delaying tactics. Skilled at bureaucratic manipulation, the Nan Sung emperors listened to criticism with ostensible grace, responded appreciatively, and made it known that they had done so, but they did not take concrete action. Sometimes an emperor would either order an investigation or express a general agreement with the criticism, thereby preventing the critics from making an issue of it by repeated remonstrances. On other occasions the emperors would listen to the critics and commend them for their courage, but, to avoid stirring up a storm, the court would explicitly forbid the circulating of private copies of the criticisms among other scholar-officials. More subtly, the court would sometimes announce an official version of such criticism, leaving out the most damaging part. Likewise, rectifying edicts that followed the acceptance of criticism often had little substance. Reconciliation at court was another technique; an emperor would deliberately, if not evasively, attribute criticism to probable misunderstanding, assemble the parties in dispute, ask them to compose their differences, caution those under attack to mend their ways, and suggest to the critics that their opinions, though valid, should be modified. The handling of severe critics who refused to change their stand required different tactics. Seemingly accepting their adverse opinion, the court might reward them by promotion to a higher position, whose functions did not include the rendering of further advice. Rarely did the court demote or punish opinion-officials, especially those with prestige; sometimes it would not even permit them to resign or to ask for a transfer. Any such move tended to damage the court's valuable Confucian image. On sensitive issues the emperors were likely to invoke their absolutist power, but this was usually handled gently, by quietly advising the opinion-officials to refrain from commenting on the issues again.

Under this bureaucratized manipulation by the court, the institution of opinion-officials degenerated. Often the emperors appointed their own friends to such posts; but just as often, when the emperors hinted that they were displeased with certain ministers, the opinion-officials dutifully responded with unfavourable evidence, thus furnishing the court with grounds for dismissals. Such Imperial manipulations served manifold purposes: safeguarding absolutist

power and its delegation to various individuals, disguising absolutism, and keeping the bureaucracy in balance.

The chief councillors. The later Nan Sung emperors preferred not to take on the awesome burden of managing the huge and complex bureaucracy. Most of them were concerned chiefly with security and the status quo.

Delegation of power in the Nan Sung

The Nan Sung court delegated a tremendous amount of power and thus had a series of dominant chief councillors; none of them, however, ever was a potential usurper. No bureaucrat during the Sung era had a political base, a hereditary hold, or a personal following in any geographic area. In addition, the size of the bureaucracy and fluidity of its composition precluded anyone from controlling it. The tenure of chief councillor was essentially dependent upon the sanction of the emperor. At times even the chief councillor had to reaffirm his loyalty along with other bureaucrats. Loyalty in absolutist terms being another name for submission, the court, bureaucratized as it was, retained its supreme position beyond challenge.

Nevertheless, the history of Nan Sung politics had much to do with powerful chief councillors, increasingly so as time went on. Kao-tsung at first had a rapid succession of ranking ministers, but none of them measured up to the difficult task at hand: seeking external security by maintaining peace with the northern empire, and internal security by undermining the power of leading generals. Only the chief councillor Ch'in Kuei did both; moreover, he increased tax revenues, strengthening the fiscal base of the court and enriching the private Imperial treasury. For these merits, he was given full support to impose tight control over the bureaucracy as long as he lived. Powerful as he was, he avoided doing anything that might arouse Imperial suspicion. He had many dissident scholar-officials banished from court, but only with Imperial sanction. He accommodated many bureaucrats, even those who neither opposed nor followed him, but he made many of them jealous of his great power and of the rapid promotions he gave to his son and grandson. Ch'in Kuei failed, however, to properly assess the wiles of his bureaucratized master, who turned out to be the more masterful politician. Upon Ch'in Kuei's death, the Emperor shifted all blame to him and recalled from banishment some of his opponents, thus restoring in time a balance in the bureaucracy.

After his voluntary abdication, Kao-tsung retained his power by using Hsiao-tsung more or less as a chief councillor. Hsiao-tsung subsequently failed to find a firm hand among his successive ministers, and the great burden on himself was probably one reason that he chose to abdicate. His son, Kuang-tsung, was mentally disturbed, unresponsive to bureaucratic consensus, and pathetically dominated by his consort. He turned against Hsiao-tsung and even refused to perform state funeral rites when the retired emperor died—an unprecedented default that shocked the court. The solution was equally unprecedented; the Empress Dowager, the palace personnel, and the ranking ministers agreed to force his abdication and oversee the accession of Ning-tsung. Through the crisis, Han T'o-chou, mentioned above in connection with the renewed war against the Juchen, moved rapidly into power. Related originally to the Empress Dowager and again to a new consort, he received deferential treatment from Ning-tsung. He was made chief councillor but found it hard to control many bureaucrats who objected to his lack of scholarly qualifications, questioned his political ability, and criticized his nepotistic appointments. Reacting to the hostility, he made first a crucial mistake and then a fatal one. First, he banned a particular school of Confucian idealists, led by Chu Hsi (see below *The rise of Neo-Confucianism*). This proved unpopular, even among neutral scholar-officials. After he rescinded the ban, he attempted to recruit support and to reunite the bureaucracy by initiating the war. After its defeat in the war, the Sung sacrificed him in its search for peace.

Rise of Han T'o-chou

Shih Mi-yüan emerged as the dominant chief councillor. Coming from a bureaucratic family background, he understood the gentle approach and the importance of accommodating various kinds of bureaucrats in order to achieve a political balance. Promoting on merit and refraining from nepotism, he restored stability. He recognized that the ideological prestige the followers of Chu Hsi had won had become a political factor, and he appointed some of their prominent leaders to highly respectable posts but without giving them real power. Like the emperors he served, he wanted to have both authority and a good political image. Ning-tsung had no son, and the chief councillor helped him adopt two heirs. When the Emperor died without designating an heir apparent, Shih Mi-yüan arbitrarily decided in favour of the younger one, which was contrary to the normal order of succession but had the backing of palace-connected personnel.

Both Li-tsung (reigned 1224/25–1264/65) and his successor Tu-tsung (reigned 1264/65–1274) indulged excessively in pleasure, though much of it was carefully concealed from the public. Shortly after the death of Shih Mi-yüan, the role of chief councillor went to Chia Ssu-tao. Though denounced in history, he actually deserves much credit. He dismissed many incompetents from the palace, the court, the bureaucracy, and the army. He curbed excessive corruption by instituting minor administrative reforms. His strict accounting made the generals personally liable for misappropriation of funds. A system of public fields was introduced, cutting into the concentration of landownership by requisitioning at a low price one-third of large estates beyond certain sizes and using the income for army expenditures when the government faced external danger and fiscal deficit. These measures, however, hurt the influential elements of the ruling class, making Chia unpopular. He too had failed to practice the gentle approach. He was denounced by those who had defected to the enemy and later reconciled their guilt by placing the blame on him.

Accomplishments of Chia Ssu-tao

Except in name, the several dominant chief councillors were nearly actual rulers by proxy. They ran the civil administration, supervised both state finance and military affairs, and controlled most scholar-officials by some varying combination of gentle accommodation and high-handed pressure. The emperors, however, kept their separate Imperial treasury—from which the government in deficit had to borrow funds—and their private intelligence systems to check upon the chief councillors. Moreover, potential competitors always existed in the bureaucracy, ready to criticize the chief councillors whenever state affairs went badly enough to displease or disturb the emperors. The chief councillors had enormous power only by virtue of the Imperial trust, and that lasted only as long as things went tolerably well.

The bureaucratic style. Regular posts in the Nan Sung civil service numbered about 20,000 without counting numerous sinecures, temporary commissions, and a slightly larger number of military officers. Besides eliminating most patronage privileges, by which high officials were entitled to obtain an official title for a son or other family member, the court occasionally considered a general reduction in the size of the bureaucracy. But vested interests always opposed it. Those who entered government service seldom dropped out or were thrown out. Meanwhile, new candidates waiting for offices came in waves from state examinations, from extra examinations on special occasions, from graduation from the National Academy, or from special recommendations and unusual sponsorship; others gained official titles because their families contributed to famine relief or to military expenditures. Thus, the ever-increasing supply of candidates far exceeded the vacancies.

According to Confucian theory, any prosperity that made possible more books in print, schools, and availability of a better educated elite was all for the good. But the original Confucian ideal intended to have the elite serve the society in general and the community in particular rather than flood the bureaucracy. Rising educational standards made the competition at examinations harder and perhaps raised the average quality of degree holders.

Families with members in the bureaucracy responded in part by successfully increasing the importance of other avenues of entrance into government service, especially the "protection" privilege that allowed high officials to secure official rank for their protégés (usually junior family members). People outside the civil service responded by altering their goals and values and by reducing the stress

on the importance of entering the bureaucracy. It is not accidental that this era saw the spread of Neo-Confucian academies that emphasized moral self-development, not success in examinations, as the proper goal of education.

Changes in the legal system

During the Sung period there was increased emphasis on morals and ethics and a continuous development of the law. The early Sung had adopted a legal code almost wholly traceable to an earlier T'ang code, but Sung circumstances differed from those of the T'ang. As a result, there was a huge output of legislation in the form of Imperial edicts and approved memorials that took precedence over the newly adopted code and soon largely displaced it in many areas of law. Sung legal bureaucrats periodically compiled and edited the results of this outpouring of new laws. The new rules not only altered the content of the (largely criminal) sphere covered by the code but also legislated in the areas of administrative, commercial, property, sumptuary, and ritual law. There were literally hundreds of compilations of various sorts of laws.

Perhaps as a result of the growth of this legal tangle from the late Pei Sung onward, magistrates made increasing use of precedents, decisions by the central legal authorities on individual cases, in reaching legal decisions. The government sought to help its officials by instituting a variety of devices to encourage officials and prospective officials to learn the law and to certify that those in office did have some familiarity with things legal. There was an increase in the writing and publication of other sorts of works concerned with the law, including casebooks and the world's oldest extant book on forensic medicine. Despite the appearance of such works, which were intended to help them, officials were under strong pressure to rule in a conservative way and to avoid rocking the boat.

Many scholar-officials sought simply to keep things quiet and maintain the appearance that there was no serious trouble. The bureaucratic style was to follow the accustomed ways in accordance with proper procedure, find expedient solutions based upon certain principles in spirit, make reasonable compromises after due consideration of all sides, and achieve smooth reconciliations of divergent views. To protect one's own career record it was essential to engage in time-consuming consultations with all appropriate offices and to report to all concerned authorities so that everyone else would have a share of responsibility. Anyone who criticized the bureaucratic style would be going against the prevalent mode of operation, namely, mutual accommodation. Even the emperor adopted the bureaucratic style.

The picture was not entirely dark. Evasions and deviations notwithstanding, the letter of the laws and the formalities of procedures had to be fulfilled. Definite limits were set on official negligence and misconduct. For example, suppressing evidence or distorting information were punishable offenses. Minor juggling of accounts went on, but outright embezzlement was never permissible. Expensive gifts were customary and even expected, but an undisguised bribe was unacceptable. The refined art of the bureaucratic style was not sophistry and hypocrisy alone; it required a circumspect adherence to the commonly accepted substandard norms, without which the maintenance of government would have been impossible.

The clerical staff. The norms for the clerks were even lower, especially in local government. Some 300 clerks in a large prefecture or nearly 100 in a small one were placed under the supervision of a few officials. The clerks had numerous dealings with various other elements in the community, whereas the officials, being outsiders, rarely had direct contacts. Holding practically lifelong tenure after benefiting from the cumulative experience of their fathers and uncles before them, the clerks knew how to operate the local administrative machinery far better than did the officials, who served only brief terms before moving elsewhere. Clerks often received inadequate salaries and were expected to support themselves with "gifts" from those needing their services. Under honest, strict, and hardworking magistrates, the clerks would recoil, but only briefly, because such magistrates would soon either gain promotion for their remarkable reputations, or their strict insistence on clean government would become intolerable to their superiors, colleagues, subordinates, and influential elements in the community who had connections with high circles. Though all bureaucrats complained of clerical abuses, many connived with the clerks and none had a viable alternative to the existing situation. One significant suggestion was to replace the clerks with the oversupply of examination candidates and degree holders, who presumably had more moral scruples. But this solution had no chance of being considered because it implied a downgrading of the status of those who considered themselves to be either potential or actual members of the ruling class.

Clerical abuses

The law did place definite limits on clerical misbehaviour. But when a clerk was caught in his wrongdoing, he knew enough to save himself—taking flight before arrest, getting a similar job elsewhere under a different name, defending himself through time-consuming procedures, appealing for leniency in sentencing, requesting a review, or applying for clemency on the occasion of Imperial celebrations. What prevented clerical abuses from getting worse was not so much official enforcement of legal limits as it was the social convention in the community. For themselves as well as for their descendants, the clerks could ill afford to overstep the socially acceptable limits.

The net result of a large bureaucracy and its supporting clerical staff, accommodating one another in various defaults, malfunctions, and misconduct within loose limits, was a declining tax yield, tax evasion by those who befriended colluding officials and clerks, and an undue shift of the tax burden onto those least able to pay.

The rise of Neo-Confucianism. The rise of the particular school of Neo-Confucianism led by Chu Hsi takes on special meaning in this context. The Neo-Confucian upsurge beginning in the late T'ang embraced many exciting extensions of the Classical vision. Noteworthy during the Pei Sung was the emergence of a new Confucian metaphysics that was influenced by Buddhism and that borrowed freely from Taoist terminology while rejecting both religions. Of relevance to Nan Sung political and social conditions was its continuous growth into a well-integrated philosophical system that synthesized metaphysics, ethics, social ideals, political aspirations, individual discipline, and self-cultivation.

Chu Hsi and his followers

The best thinkers of the early Nan Sung were disillusioned by the realization that previous Neo-Confucian attempts had failed. Reforms that had sought to apply statecraft had ended in abuses and controversies. The spread of education had not coincided with an uplifting of moral standards. The loss of the central plains was a great cultural shock, but to talk of recovering the lost territory was useless unless it was preceded by a rediscovery of the true meaning of Confucianism. To Chu Hsi and his followers, a state permeated by true Confucian practices would be so internally strong and would have such an attraction for outsiders that the retaking of the north would require only a minimal effort; a state lacking true Confucian practices would be so internally weak and unattractive that retaking the lost territories would be quite impossible.

Moreover, threatened by the Juchen adoption of the same heritage, the Sung felt driven to make an exclusive claim to both legitimacy and orthodoxy. Such a claim required that the new departures be interpreted as reaffirmation of ancient ideals. Thus, the intellectual trend that developed under Chu Hsi's leadership was at first referred to as Tao Hsüeh (the School of True Way) and later as Li Hsüeh (the School of Universal Principles). Education, to the thinkers of this school, meant a far deeper self-cultivation of moral consciousness, the ultimate extent of which was the inner experience of feeling at one with universal principles. These men, who might be described as transcendental moralists in Confucianism, also made a commitment to reconstruct a moral society—to them the only conceivable foundation for good government. With missionary-like zeal, they engaged in propagation of this true way and formed moral-intellectual fellowships. Chu Hsi, the great synthesizer, ranked the Classics in a step-by-step curriculum, interpreted his foremost choices, collectively known as the *Four Books,* summed up a monumental history in a short version full of moralistic judgments, prepared other extensive writings and sayings

of his own, and opened the way for an elementary catechism, entitled the "Three Word Classics," that conveyed the entire value system of this school in simple language for what approximated mass education.

Many idealistic scholars flocked to Chu Hsi, his associates, and his disciples. Frustrated and alienated by the prevalent conditions and demoralizing low standards, these intellectuals assumed a peculiar archaic and semireligious life-style. Prominent in scholarship, educational activities, and social leadership and filling some relatively minor government posts, they asserted their exclusive ideological authority with an air of superiority, much to the displeasure of many conventional Confucians. Though they were not keen about politics, the prestige they acquired was an implicit threat to those in power. The chief councillor Han T'o-chou was particularly alarmed when he found some of his political adversaries sympathetic to and even supporting this particular school. A number of other bureaucrats at various ranks shared Han's alarm; one after another, they accused this school of being similar to a subversive religious sect, calling it a threat to state security and attacking its alleged disrespect for the court. The school was proscribed as false learning and un-Confucian. Several dozen of its leaders, including Chu Hsi, were banished, some to distant places. Thenceforth, all state examination candidates had to declare that they had no connection with the school.

The government's response to Chu Hsi

Most historical accounts follow the view that the controversy was another example of factional strife, but that was not the case. The attackers were not a cohesive group, except for their common resentment toward this school, nor was the school itself an active group in politics. The conflict was in fact one between two polarized levels—political power and ideological authority. The nature of the Confucian state required that the two should converge if not coincide.

The persecution boomeranged by making heroes out of its victims and arousing sympathy among neutral scholar-officials. Realizing his mistake a few years later, Han lifted the ban. Most historical accounts leave an erroneous impression that, once the ban was removed, the Chu Hsi school of Neo-Confucianism by its preeminence soon gained wide acceptance, which almost automatically raised it to the coveted status of official orthodoxy. But in reality the rise to orthodoxy was slow and achieved by political manipulation, occasioned by an internal crisis of Imperial succession and then by the external Mongol threat. Shih Mi-yüan, the chief councillor who made Li-tsung emperor, created circumstances that forced the elder heir to commit suicide. This was damaging to the image of the court and to that of Shih himself. Mending political fences, he placed a few of the school's veteran leaders in prestigious positions in order to redress the balance of the bureaucracy. In 1233, the year before the Mongol conquest of Juchen, the Mongols honoured Confucius and rebuilt his temple in Peking. In 1237 their emerging nomadic empire, already occupying a large portion of North China, reinstituted a civil service examination, thus claiming that it, too, was a Confucian state. Threatened both militarily and culturally, the Nan Sung made Chu Hsi's commentaries official, his school the state orthodoxy, and its claim the accepted version—that the true way of Confucius had been lost for more than 1,000 years and that the line of transmission was not resumed until, inspired by the early Pei Sung masters, Chu Hsi reestablished it. This implied that whatever Confucianism the Mongols took over was but a pale imitation and without legitimacy.

Internal solidarity during the decline of the Nan Sung. Honouring the Chu Hsi school did not reinvigorate the Nan Sung administration, but the military, despite some weaknesses, maintained an effective defense against the Mongols for four decades—the longest stand against Mongol invasions anywhere. The final Sung defeat came in part because the Mongol forces, frustrated for many years in their attempts to break the main Sung line of resistance, drove through territories to the west and outflanked the Sung defenders. The Sung capital, Lin-an, finally fell in 1276 without much fighting, after high-ranking officials and officers had fled. The empire finally came to an end in 1279, after its last fleet had been destroyed near Canton, when a loyal minister with the boy pretender to the throne committed suicide by jumping into the sea.

Later Chinese historians attempted to explain the fall of the Nan Sung as the result of internal decay and abuses, and so they stressed the problems of heavy taxation, inflation of paper currency, bureaucratic laxity, and clerical abuses. The absence of any large-scale uprisings among the peasantry, however, suggests that they overstated the seriousness of such problems. To explain this lack of major uprisings, most historical accounts point to Chinese patriotism because the war against the Mongols was for cultural rather than merely dynastic survival. Though partly true, this was not the only reason. The impressive internal solidarity involved many other factors: (1) the government mobilized the resources of the wealthiest region, that of the lower Yangtze, without overburdening other parts; (2) the tax burden and the emergency requisitions fell mostly upon the prosperous urban sectors rather than on rural areas, the backbone of the empire; (3) scholar-officials in many areas, in spite of their shortcomings, were sophisticated in the art of administration, moving quickly to put down small uprisings before they got larger, or offering accommodative terms to induce some rebel leaders to come over while dividing the rest. Finally, the Neo-Confucian values had pervaded the country through more books, more schooling, and more efforts by Neo-Confucians to promote moral standards, community solidarity, and welfare activities, and through widespread Neo-Confucian roots planted at the local levels by half-literate storytellers, makeshift theatres, and traveling companies in various performing arts.

Factors in Nan Sung solidarity

The examination system itself played a major role in the Confucianization of Chinese society. Only a small percentage of the candidates actually passed the degree examinations and entered the civil service. The vast majority, thoroughly imbued with Confucian studies, returned to the larger society, often to serve as teachers to the next generation. Furthermore, the examination system reinforced the deeply Confucian character of the curriculum, from the lowest level of primary education to the highest level in the academies. Children began imbibing Confucian moral precepts when they began to read. These precepts stressed loyalty, and that in turn probably helped bolster the strength of the dynasty in the face of foreign invasion and helped limit internal disloyalty.

SUNG CULTURE

The Sung was an era of great change in most facets of Chinese life. Some of these developments were the outgrowths of earlier patterns, while others were largely born under that dynasty. These developments often related to or were made possible by major changes in Chinese economic life.

The agricultural revolution of the Sung

An agricultural revolution produced plentiful supplies for a population of more than 100,000,000—by far the largest in the world at the time. Acreages under cultivation multiplied in all directions, stretching across sandy lands, climbing uphill, and pushing back water edges. A variety of early ripening rice, imported during the 11th century from Champa in modern Kampuchea, shortened farming time to fewer than 100 days, making two crops a year the norm and three crops possible in the warm south. Among other new crops the most important was cotton, which provided clothing for rich and poor alike; silk and hemp were also important. Improved tools, new implements, and mechanical devices that raised manpower efficiency were widely used and found their way into guidebooks used by the literate community leaders. Mineral productivity of such substances as gold, silver, lead, and tin also increased. Consumption of iron and coal grew at a faster rate from 850 to 1050 than it had in England during the first two centuries of the Industrial Revolution. The Chinese, however, never combined the two resources to generate power mechanically.

Manufacturing made tremendous headway within the skill-intensive pattern but with the aid of new devices, better processing, a beginning of division of labour, and expertise. Chinese porcelain attained international fame. Though information on ordinary handicrafts was available

in handbooks and encyclopaedias, advanced skills were guarded as trade secrets. Specialization in production and regional trade stimulated mutual growth.

Improved transportation

Transportation facilities improved, allowing production away from the sources of supplies and making products available to distant parts. The state maintained highways, with staffed stations, for official travel and a courier service network, the latter being an index of centralized government control. Along the highways and branching byways stood private hostels and inns frequented by private traders. Rivers carried tribute vessels and barges, private shipping, transfer crafts, fishing boats, and pleasure yachts. Large ships with multiple decks were propelled by fast-moving wheels paddled by manpower; many sailed on the high seas, aided by accurate compasses, charts, and instruments as well as by experience in distant navigation. The expanding sea trade, apart from that with Japan and Korea, moved southward and linked up with merchants from Persia and Arabia. Some Chinese merchants began to settle in Southeast Asia. For the first time in history, Chinese naval forces assumed a vital military role, though China had not become a sea power.

An advanced money economy was everywhere in evidence. Many cultivated lands produced cash crops. By 1065 the Pei Sung government was taking in annual cash tax payments that were 20 times what the T'ang had received in 749. The income of the Nan Sung consisted of more cash revenues than grain and textile receipts. The economy had progressed to such a state that it needed more means of exchange. Merchants used drafts called *fei-ch'ien* ("flying money") and certificates of deposits made elsewhere. State monopoly agencies in salt and tea followed with their respective certificates, which were as good as money. The government first permitted printed paper money for limited regional circulation and then authorized it as nationwide legal tender. (China was the first country to do so.)

Busy transactions approached a commercial revolution, carried on by rapid calculations on the abacus, a specialized service skill that remained unmatched until the appearance of adding machines and computers. Cities changed: the T'ang pattern of walled-in blocks, each for a particular trade, broke down; stores appeared in various parts of cities, and trade guilds proliferated. Though official documents and scholarly essays adopted a downgrading tone toward commercial activities, Sung China became a society of wholesalers, shippers, storage keepers, brokers, traveling salesmen, retail shopkeepers, and peddlers. Urban life reached a new intensity. The populations of several metropolitan areas approached 1,000,000.

Changes in urban life

Crowding was serious. Houses usually had narrow frontages. Fires were frequent and disastrous. Neighbourhood fire squads, with water containers at hand, could not prevent destruction, and some fires lasted several days. Nonetheless, prosperity was the keynote of urban life. Teahouses, wine shops, exquisite cuisines, and catering services for private parties existed in multitude and variety. Pleasure grounds provided daily amusement and festival merriment with acrobats, jugglers, wrestlers, sword swallowers, snake charmers, fireworks, gambling, performing arts of all sorts, puppet shows, storytellers, singing girls, and professionally trained courtesans. Upper-class families enjoyed higher culture, with such diversions as music, pets, intricate games, hobbies, calligraphy, painting, and poetry. Noticeably declining were hunting, horseback riding, and polo. Gentility displaced sportsmanship. The prosperous cities also provided easy prey for pickpockets and professional thieves. Inasmuch as pauperism appeared in cities, parallel to rural underemployment and unemployment, the government undertook relief and such welfare measures as orphanages, nursing homes for the aged poor, charitable graveyards, and state pharmacies.

Expansion of knowledge

Knowledge expanded because of specialization. Medicine embraced such skills as acupuncture, obstetrics, dentistry, laryngology, ophthalmology, and treatment of rheumatism and paralysis. The demand for improvement in technology, aided by certain concerns of the Neo-Confucian philosophy, helped to promote numerous investigations approaching science. Literacy spread with printing, which evolved from rubbing through block printing to the use of movable type that facilitated a large quantity of production at reduced cost. A large number of scholars achieved high standing through Classical studies, newly developed archaeology, philosophical interpretations, statecraft ideas, classical forms of poetry, an evolving lyric poetry called *tz'u,* which had its origin in singing, and written versions of popular songs, called *san-ch'u.* Of greatest influence on scholar-officials in succeeding generations was a masterly prose style that was original and creative but that was always used in the name of reviving ancient models. Diversified and specialized developments widened knowledge so much that scholars compiled voluminous histories, collected works, comprehensive handbooks, compendiums, and encyclopaedias. Fine arts also reached new heights.

The term early modern has often been applied in describing Sung culture because it not only advanced beyond the earlier pattern in China and far ahead of the rest of the world at the time but it also had many startlingly new features that approximated later developments in western Europe. This characterization, though helpful to highlight and appreciate the Sung progress, tends to be misleading. The so-called early modern stage did not pave the way for more modernity later. On the contrary, the Sung pattern attained cultural stability, giving rise to the myth of an unchanging China.

These conflicting images stemmed from the cultural and regional diversity of the Sung, in which modern-style advances existed alongside continuing older practices. In some areas such as the delta lands immediately south of the Yangtze River, sizable estates grew up with a complicated social pattern characterized by tenant farming. Elsewhere, in less well-developed areas, there was a greater proportion of owner-farmers, while in still other regions, the landlords tried to bind the tillers to the soil. The same confusion was reflected in the status of women. During the Sung the notorious practice of foot binding first became common, clearly marking a fall in the status of women, but there is evidence that during the Nan Sung (unlike any other Chinese dynasty) daughters as well as sons could inherit property in their own names. Furthermore, Sung families tried in various ways to strengthen the ties created by the marriages of their daughters to other families.

The extraordinarily rapid pace of economic and technological change that marked the Pei Sung seems to have slowed during the Nan Sung. For reasons that are not wholly clear, Chinese society did not break through its inherited patterns in any radically new ways. It may be that, with an abundance of inexpensive labour, economic rationality moved men to produce through increased amounts of labour rather than through innovation or capital investment. This disincentive to investment helped create a relatively stable economic and technological pattern that remained with little change for centuries thereafter. Despite this slowing of economic and technological development, however, the Sung did give birth to changes. It not only saw the creation of a new Confucian synthesis but also helped create the devices that spread the new ideas among the people at large. The urban and urbanized culture that arose in the Sung was retained and developed in succeeding dynasties, when the early modern (or neotraditional) pattern created in the Sung provided both the model for and the basis of the gradual transformation of some aspects of Chinese life that belied the image of China as unchanging. (J.T.C.L./B.E.McK.)

The Yüan, or Mongol, dynasty

THE MONGOL CONQUEST OF CHINA

Genghis Khan rose to supremacy over the Mongol tribes in the steppe in 1206, and within a few years he attempted to conquer northern China. By securing the allegiance of the Tangut state of Hsi Hsia in what are now Kansu and northeastern Tibet (1209), he disposed of a potential enemy and prepared the ground for an attack against the Chin state of the Juchen in northern China. At that time the situation of Chin was precarious: the Juchen were exhausted by a costly war (1206–08) against their hereditary enemies, the Nan Sung. Discontent among the

Preparations for war against China

non-Juchen elements of the Chin population (Chinese and Khitan) had increased, and not a few Chinese and Khitan nobles defected to the Mongol side. Genghis Khan, in his preparation for the campaign against Chin, could therefore rely on foreign advisers who were familiar with the territory and the conditions of the Chin state.

Invasion of the Chin. The Mongol armies started their attack in 1211, invading from the north in three groups; Genghis Khan led the centre group himself. For several years they pillaged the country; finally, in 1214 they concentrated upon the central capital of the Chin, Chung-tu (modern Peking). Its fortifications proved difficult to overcome, so the Mongols concluded a peace and withdrew. Shortly afterward the Chin emperor moved to the southern capital at Pien (modern K'ai-feng). Genghis Khan considered this a breach of the armistice; a renewed attack brought large parts of northern China under Mongol control and finally resulted in 1215 in the capture of Chung-tu (renamed Ta-tu in 1272). The Mongols had had little or no experience in siege craft and warfare in densely populated areas; their strength had been chiefly in cavalry attacks. The assistance of defectors from the Chin state probably contributed to this early Mongol success. In subsequent campaigns the Mongols relied even more upon the sophisticated skills and strategies of the increased number of Chinese under their control.

After 1215 the Chin were reduced to a small buffer state between the Mongols in the north and Sung China in the south, and their extinction was but a matter of time. The Mongol campaigns against Hsi Hsia in 1226–27 and the death of Genghis Khan in 1227 brought a brief respite for Chin, but the Mongols resumed their attacks in 1230.

The Sung Chinese, seeing a chance to regain some of the territories they had lost to the Juchen in the 12th century, formed an alliance with the Mongols and besieged Pien in 1232. The Emperor of Chin left Pien in 1233, just before the city fell, and took up his last residence in Ts'ai Prefecture (Honan), but this refuge was also doomed. In 1234 the Emperor committed suicide, and organized resistance ceased. The southern border of the former Chin state—the Huai River—now became the border of the Mongol dominions in northern China.

Invasion of the Sung. During the next decades there was an uneasy coexistence between the Mongols in northern China and the Sung state in the south. The Mongols resumed their advance in 1250 under the grand khan Möngke and his brother Kublai Khan—grandsons of Genghis Khan. Their armies outflanked the main Sung defenses on the Yangtze River and penetrated deeply into southwestern China, conquered the independent Tai state of Nan Chao (in what is now Yunnan), and even reached present-day northern Vietnam. Möngke died in 1259 while leading an army to capture a Sung fortress in Szechwan, and Kublai succeeded him. Kublai sent an ambassador, Hao Ching, to the Sung court with an offer to establish peaceful coexistence. Hao did not reach the Sung capital of Lin-an (now Hang-chou), however, but was interned at the border and regarded as a simple spy. The Sung chancellor, Chia Ssu-tao, considered the Sung position strong enough to risk this affront against Kublai; he thus ignored the chance offered by Kublai and instead tried to strengthen the military preparations against a possible Mongol attack. He secured military provisions by a land reform that included the confiscation of land from large owners, but this alienated the greater part of the landlord and official class. The Sung generals, whom Chia distrusted, also had grievances, which may explain why a number of them later surrendered to the Mongols without fighting.

Mongol penetration into southwestern China

From 1267 onward, the Mongols, this time assisted by numerous Chinese auxiliary troops and technical specialists, attacked on several fronts. The prefectural town of Hsiang-yang (modern Hsiang-fan) on the Han River was a key fortress, blocking the access to the Yangtze River. The Mongols besieged Hsiang-yang for five years (1268–73). The Chinese commander finally surrendered in 1273, after he had obtained a solemn promise from the Mongols to spare the population, and he took office with his former enemies.

Kublai Khan's warning to his forces not to engage in indiscriminate slaughter seems to have been heeded to a certain extent. Several prefectures on the Yangtze River surrendered; others were taken after brief fighting. In January 1276, Mongol troops reached Lin-an. Last-minute attempts by the Sung court to conclude a peace failed, and the Mongol armies took Lin-an in February. The reigning Sung empress dowager and the nominal emperor—a boy—were taken to Ta-tu and granted an audience by Kublai Khan.

National resistance in the Sung state continued, however, and loyalists retreated with two Imperial princes into the southern province of Fukien and from there to the region of Canton. In 1277 the last remnants of the court left Canton and eventually fled the mainland by boat. A faithful minister drowned himself and the last surviving Imperial prince in the ocean in March 1279. When organized resistance ceased soon afterward, foreign invaders controlled the whole Chinese empire for the first time in history.

CHINA UNDER THE MONGOLS

Mongol government and administration. After their initial successes in northern China in 1211–15, the Mongols faced the problem of how to rule and extract material benefits from a largely sedentary population. They were assisted by Khitan and Chinese and even Juchen renegades; these defectors were treated as "companions" (*nökör*) of the Mongols and were given positions similar to the higher ranks of the steppe aristocracy—their privileges included the administration and exploitation of fiefs considered as their private domain.

Mongol use of defectors

Early Mongol rule. The government system during the early years of the Mongol conquest was a synthesis of Mongol military administration and a gradual return to Chinese traditions in those domains ruled by former subjects of the Chin state. The most important office or function in Mongol administration was that of the *darughatchi* (or seal bearer), whose powers were at first all-inclusive; only gradually were subfunctions entrusted to specialized officials in accordance with Chinese bureaucratic tradition. This refeudalization of northern China along Mongol lines with a slight understructure of Chinese-type bureaucrats lasted for many years.

The central administration of Mongol China was largely the creation of Yeh-lü Ch'u-ts'ai, originally a Chin state official of Khitan extraction who had acquired a profound Chinese scholarship and had become one of Genghis Khan's trusted advisers. Yeh-lü continued to serve under Ögödei, who became grand khan in 1229, and persuaded him to establish a formal bureaucracy and to replace indiscriminate levies with a rationalized taxation system along Chinese lines. An important part of Yeh-lü's reforms was the creation of the Central Secretariat (Chung-shu sheng), which centralized the civilian administration and achieved some continuity. The territory was divided into provinces, and the provincial administrations were responsible for regularized taxation. The people had to pay a land tax and a poll tax, either in kind (textiles and grain) or in silver. Merchants had to pay a sales tax. Monopolies on wine, vinegar, salt, and mining products were also introduced. All this enabled the treasuries of the Mongol court to accumulate considerable wealth.

In spite of the success of his economic policy, Yeh-lü's influence decreased during his later years. One reason was bitter opposition from the Mongol feudatories and from those Chinese, Juchen, and Khitan nobles who were used to ruling independently in their appanages, which they exploited at will. Also, Ögödei himself apparently lost interest in the internal conditions of the Mongol dominion in China. During the 1230s Muslims from the Middle East had already begun to fill the higher positions at the Mongol court, and their ruthless exploitation of the Chinese created widespread resentment of Mongol rule. A relapse into feudal anarchism seemed inevitable, and Yeh-lü's reforms fell into temporary abeyance. China was ruled more or less like a colony by the foreigners and their allies.

Changes under Kublai Khan and his successors. Kublai Khan's ascendancy in 1260 marked a definite change in Mongol government practice; Kublai moved the seat

of Mongol government from Karakorum in Mongolia to Shang-tu (Upper Capital) near modern To-lun in Inner Mongolia. In 1267 the official capital was transferred to Chung-tu, where Kublai ordered the construction of a new walled city, replete with grand palaces and official quarters, that was renamed Ta-tu ("Great Capital") before its completion. Under its Turkicized name, Cambaluc (Khanbaliq, "The Khan's Town"), the capital became known throughout Asia and even Europe. But, true to nomad traditions, the Mongol court continued to move between these two residences—Shang-tu in summer and Ta-tu in winter. With the establishment of Ta-tu as the seat of the central bureaucracy, Mongolia and Karakorum no longer remained the centre of the Mongol Empire. Mongolia began to fall back to the status of a northern borderland, where a nomadic way of life continued and where Mongol grandees, dissatisfied with the growing Sinicization of the court, repeatedly engaged in rebellions.

Kublai, who even prior to 1260 had surrounded himself with Chinese advisers such as the eminent Buddho-Taoist Liu Ping-chung and several former Chin scholar-officials, was still the nominal overlord of the other Mongol dominions (*ulus*) in Asia. By then, however, his Chinese entourage had persuaded him to accept the role of a traditional Chinese emperor. A decisive step was taken in 1271 when the Chinese dominion was given a Chinese dynastic name—Ta Yüan, the "Great Origin." Before this the Chinese name for the Mongol state was Ta Ch'ao ("Great Dynasty"), introduced *c.* 1217. It was a translation of the Mongol name Yeke Mongghol Ulus ("Great Mongol Nation") adopted by Genghis Khan *c.* 1206. The new name, however, was a departure from Chinese traditions. All earlier Chinese dynasties were named after ancient feudal states or geographic terms; even the Khitan and the Juchen had followed this tradition by naming their states Liao (after the Liao Ho in Manchuria) and Chin ("Gold," after a river in Manchuria that had a Juchen name with that meaning). Yüan was the first nongeographic name of a Chinese dynasty since Wang Mang established the Hsin dynasty (AD 9–25).

Foundation of the Yüan dynasty

During the 1260s the central bureaucracy and the local administration of the Chinese empire were remodeled on Chinese lines, with certain alterations introduced by the Chin, or Juchen, state. The Central Secretariat remained the most important civilian authority, with specialized agencies such as the traditional six ministries of finance, war, officials, rites, punishments, and public works. The Shu-mi yüan (Military Council) was another institution inherited from previous dynasties. A Yü-shih t'ai (Censorate) was originally created for remonstrations against the emperor and criticism of policies, but it became more and more an instrument of the court itself and a tool to eliminate other members of the bureaucracy. In the main, the territorial divisions followed Chinese models, but the degree of local independence was much smaller than it had been under the Sung; the provincial administrations were actually branches of the Central Secretariat. The structures of the various provincial administrations throughout China were smaller replicas of the Central Secretariat. According to Chinese sources, in 1260–61 the lower echelons in the Central Secretariat were mostly Chinese; the high offices, however, even if they had traditional Chinese names, were reserved for non-Chinese. Surprisingly, Kublai Khan had few Mongols in high administrative positions; apparently suspicious of some of his tribal leaders, he preferred absolute foreigners. The military sphere was affected least by the attempts to achieve a synthesis between Chinese and native ways of life; there the Mongol aristocracy remained supreme.

Too many antagonistic social and ethnic groups existed within the Yüan government to secure a stable rule. The traditional Chinese value system had largely disappeared, and no political ethics had replaced it. While personalized loyalty focused on the ruler, the companionship of *nökör* relations was not enough to amalgamate the heterogeneous ruling group into a stable body. This unbalanced system of government could function only under a strong ruler; under a weak or incompetent emperor disintegration was certain, and a decline in efficiency resulted.

Problems of non-assimilation

The former scholar-officials of China remained to a great extent outside the governmental and administrative structure; only minor positions were open to them. The Mongols never made full use of the administrative potential of the scholar-officials, fearing their competence and abilities. The ruling foreign minority in China was more an elite of the colonialist type than a part of the Chinese social system.

The unwillingness of the Mongols to assimilate with the Chinese is shown by their attempts to cement the inequalities of their rule. After the Sung Empire had been conquered, the population of China was divided into four classes. The first class was the Mongols themselves, a tiny but privileged minority. Next came the *se-mu jen* ("persons with special status"), such confederates of the Mongols as Turks or Middle Eastern Muslims. The third group was called the *han-jen* (a term that generally means Chinese but that was used to designate the inhabitants of only northern China); this class included the Chinese and other ethnic groups living in the former Chin state, as well as Hsi Hsia, Juchen, Khitan, Koreans, Po-hai, and Tangut, who could be employed in some functions and who also formed military units under Mongol leadership. The last group was the *man-tzu,* an abusive term in Chinese, meaning "southern barbarian," which designated the former subjects of Sung China, about three-fourths of the Chinese empire. The lowest stratum in Yüan China was the slaves, whose numbers were quite considerable. The slave status was hereditary, and only under certain conditions could a slave be freed.

More than 80 percent of the taxpayers came from the *man-tzu* group, which was generally barred from holding higher office (only rarely would one of them rise to some prominence). The Mongols and the *se-mu jen* were tax-exempt and enjoyed the protection of the law to a higher degree than did the *han-jen* and *man-tzu.*

The formal distinction between various ethnic groups and the corresponding graded status was no Mongol invention but a social differentiation inherited from the Chin state. In the same way, many institutions were taken over from the Chin. Law in Yüan China was based partly on the legislation of the Chin and partly on traditional Chinese law; but Mongol legal practices and institutions also played a great role, particularly in penal law. The Yüan legal code has been preserved in the dynastic history, *Yüan shih,* and other sources. In addition, many rules, ordinances, and decisions of individual cases are collected in such compilations as *Yüan tien-chang,* which throw much light not only on the legal system but also on social conditions in general.

Mongol and Chinese dualism was also reflected in the problem of administrative documents and languages. Few of the ruling Mongols, even in the later years of the Yüan, knew Chinese, and the number who mastered the Chinese script was still smaller. On the other hand, very few Chinese bothered to learn the language of the conquerors. Administration and jurisdiction, therefore, had to rely largely on interpreters and translators. Mongol was the primary language; most decisions, ordinances, and decrees were originally drafted in Mongol, and a Chinese interlineary version was added. This Chinese version was in the colloquial language instead of the formal documentary style, and it followed the Mongol word order so that these Chinese versions must have seemed barbaric to the native literati. Many of these Chinese versions have survived in such collections as *Yüan tien-chang.*

Economy. The Mongol conquest of the Sung Empire had for the first time since the end of T'ang reunified all China. Sung China had traded with its neighbours, the Liao and Chin, but trade had been strictly controlled and limited to authorized border markets. The Mongol conquest therefore reintegrated China's economy. The Mongol administration, in its desire to utilize the resources of the former Sung territory, the most prosperous part of China, tried to promote internal trade and aimed at a fuller integration of north and south. The region around the capital was dependent on grain transports from the south, and large quantities of food and textiles were needed to keep the Mongol garrisons. The Grand Canal, which

Reintegration of internal trade

had linked the river systems of the Yangtze, the Huai, and the Huang since the early 7th century, was repaired and extended to Ta-tu in 1292–93 with the use of corvée under the supervision of a distinguished Chinese astronomer and hydraulic engineer, Kuo Shou-ching—an action entirely within Chinese tradition. This was preceded, however, by another measure in the field of economic communications that was unorthodox in Chinese eyes: in about 1280, concessions for grain transport overseas were granted to some private Chinese entrepreneurs from the southeastern coastal region (some Chinese government officials were traditionally antagonistic toward private trade and enterprise, an attitude that the ruling Mongols did not share). These private shipowners transported in their fleets grain from the lower Yangtze region to northern Chinese harbours and from there to the capital. Early in the 14th century, however, these private fleet owners, who had made huge fortunes, were accused of treason and piracy, and the whole action was abolished. The Mongol government never replaced them with government fleets.

Another factor that contributed to the flourishing internal trade in China was the unification of currency. The Sung and Chin had issued paper money but only in addition to bronze coins, which had remained the basic legal tender. The Yüan government was the first to make paper money the only legal currency throughout the empire (1260). This facilitated financial transactions in the private sector as well as in the state treasuries. As long as the economy as such remained productive, the reliance on paper money as the basic currency had no detrimental effects. Only when the economy began to disintegrate under the last Mongol ruler did the paper money become gradually valueless and inflation set in. One reason for the paper currency might have been that much bronze and copper was used for the Buddhist cult and its statues, another that metal ores in China proper were insufficient to supply enough coins for some 80,000,000 people.

Religious and intellectual life. The Mongols did not try to impose their own religion (a cult of Heaven, the forces of nature, and shamanistic practices) on their subjects. This gave comparative freedom to the existing religions in China. These included what the Mongol rulers considered to be the *san chiao* ("three teachings"): Taoism, Buddhism, and Confucianism. Both Taoism and Buddhism retained their distinctive identities and organizations; although they often rivaled each other, they were not mutually exclusive. The Neo-Confucianism of the Chu Hsi school enjoyed orthodox status after the 1310s, but adherents of the three teachings interacted philosophically and intellectually in a way that popularized the "amalgamation" of the three schools among the common people and literati, if not the foreign residents, of China.

Mongol religious policies

Taoism. Under the Chin dynasty several popular Taoist sects had flourished in northern China, and Genghis Khan had apparently been impressed by the Taoist patriarch Ch'ang-ch'un. In 1223 Genghis Khan granted to Ch'ang-ch'un and his followers full exemption from taxes and other duties demanded by the government; this was the first of a series of edicts granting special privileges to the clergy of the various religions in China.

For some time it seemed as if Chinese Taoism would win favour with the Mongol rulers at the expense of Chinese Buddhism. The Buddhists, however, also profited from the open-minded attitude at the court; they tried to win influence within the Imperial family, prompted by the fact that many Buddhist institutions had been occupied by the Taoists, who relied on Mongol favour. Under the grand khan Möngke, several discussions were held between the Taoist and Buddhist clergy (1255–58), ending in a ruling that the former Buddhist temples should be returned to their original purpose. Imperial orders also outlawed some apocryphal Taoist texts, in which Buddhism was presented as a branch of Taoism and the Buddha as a reincarnation of Lao-tzu, the founder of Taoism. But Taoism as such continued to exist under the Yüan, and the fiscal privileges originally granted to the Taoist followers of Ch'ang-ch'un were extended on principle to all clergies.

Buddhism. The spokesmen of Chinese Buddhism under the early Mongol rulers came from the Ch'an sect (meditation Buddhism). Their high intellectuality and refined aestheticism, however, did not appeal to the Mongols, who felt more attracted by the mixture of magic practices, rather nebulous metaphysics, and impressive symbolism in the visual arts of Tibetan Buddhism. Kublai Khan appointed a young Tibetan lama known by the honorific name of 'Phags-pa as Imperial teacher (*ti-shih*); 'Phags-pa became the head of the Buddhist church in all Mongol dominions, including China. A special government agency to deal with Buddhism was established in 1264 and served as a sort of bureau for the Imperial teacher; it was in charge not only of Buddhist affairs in general but also of Tibetan affairs, although Tibet remained outside the administration of China proper, and no Mongol garrisons were ever established in Tibet. Tibetan politicians had thus succeeded in winning over the Mongol court and in retaining a more than nominal independence.

After the conquest of Sung China, a special agency for the supervision of Buddhism in southern China was established and placed under the control of another Tibetan lama. There thus existed two supervisory offices for Buddhism—one in Ta-tu for northern China and Tibet and one in Lin-an for southern China. The southern office caused great resentment among Chinese Buddhists and the population at large by its brutal and avaricious procedures, seizures of property, and extortions from the population. Throughout the Yüan dynasty, complaints continued against the arrogant behaviour of Tibetan lamas. (Under the last emperor, Togon-temür, Tibetan clerics introduced the court to sexual rites calling for intercourse with consecrated females—practices not unfamiliar in Indian and Tibetan cultures but shocking to the Chinese elite.)

Complaints against Tibetan lamas

Although Buddhism had won a victory among the ruling minority of China, it was a foreign rather than a Chinese Buddhism. The national varieties of Buddhism, especially Ch'an Buddhism, continued to exist, and monasteries in southern China sometimes became islands of traditional civilization where monks and lay Buddhists alike cultivated poetry, painting, and all the intellectual pastimes of the Chinese literati class; but, on the whole, Chinese Buddhism suffered from the general conditions in the Yüan Empire. The exemption from taxes and corvée attracted many persons to monastic life for purely utilitarian reasons, and, the more society disintegrated, the more people sought refuge behind the monastery walls. In about 1300 the number of monks throughout China was estimated at 500,000, and it must have grown during the last decades of Mongol rule. Monks played a great role in the rebellions to which the Yüan Empire eventually succumbed; also, the first Ming emperor had been a monk for some time.

Foreign religions. Tibetan Buddhism always remained outside Chinese civilization, as did other imported religions. A certain number of Muslims came to China, all from the Middle East or from Central Asia. The Turkic Öngüt tribe was largely Nestorian Christian. Many tombstones have been preserved with a bilingual Turkic and Chinese inscription, but none of these believers seems to have been Chinese by origin; a census taken about 1300 in Chen-chiang (in the present-day province of Kiangsu) lists the Nestorians together with foreign nationalities. The number of Nestorian Christians in China was so great that in 1289 a special agency for their supervision was established in Ta-tu. Manichaeism, which had spread to China under the T'ang, became extinct under the Yüan as an organized religion; but some Manichaean communities were probably absorbed by messianic Buddhist sects such as the White Lotus sect, a group that attracted many followers among the Chinese lower classes.

Confucianism. Confucianism was perceived by the Mongols as a Chinese religion, and it had mixed fortunes under their rule. The teachings of the Neo-Confucian school of Chu Hsi from the Sung period were introduced to the Mongol court at Chung-tu in the late 1230s but were confined to limited circles there and in North China. Confucian scholars enjoyed the benefits extended to the clergy of all religions, but they were dealt a strong blow by the discontinuation of the literary examinations following the Mongol conquest. For many centuries the examinations, based on Confucian texts, had been the basis for the selec-

tion of officials and for their privileged position within the state and society. After Kublai's accession, Confucianism had a more cordial reception at the Mongol court through the efforts of Chinese advisers like Liu Ping-chung and the great Confucian master Hsü Heng. Under their stewardship a certain Confucianization took place in government and education. Chinese rituals were performed for a while in the dynastic temple (*t'ai-miao*), erected in Chung-tu in 1263. State sacrifices were offered to Confucius, and the study of the Classics was encouraged. Many of the rites observed at the court that were either Tibetan Buddhist or inherited from the Mongol nomadic past were continued, however. The emperor Buyantu (ruled 1311–20), one of the most Sinicized Mongol rulers, reintroduced the examination system in 1313, but it remains doubtful how well the examinations functioned. They certainly did not guarantee an official career, as those under the Sung and, to a certain extent, under the Chin had done.

Examination system reintroduced

The system of the Yüan, as introduced in 1313, provided different types of curricula for Mongols, other foreigners (*se-mu jen*), and Chinese; also, the requirements were different—Chinese had to show their complete mastery of the curriculum, whereas Mongols and other foreigners had to give only a mediocre performance. This inequality was even formalized for the candidates who were to be admitted to the state academy (*kuo-tzu chien*). The first examinations were held in the presence of the Emperor in 1315, and, of the 300 persons granted the title of doctor (*chin-shih*), 75 were Mongols, 75 were other foreigners, 75 were northern Chinese (*han-jen*), and 75 came from southern China; they all received official positions within the bureaucracy, Mongols the higher and Chinese the lesser posts. The positions of power within the hierarchy remained in the hands of the Mongols and other foreigners.

Under Buyantu, for the first time, the interpretation and commentaries of the Neo-Confucian school were made obligatory. This cemented Neo-Confucian ideology not only among the Chinese literati who wished to pass an examination but also for future generations. Chinese Confucian orthodoxy from the 14th to the 19th century therefore rested largely on the foundations it had received under the Yüan. In spite of all this, Classical scholarship under the Yüan did not produce a single remarkable work but struggled under an adverse political and intellectual climate. Striving to preserve their sacred tradition, the Confucian scholars were content with expounding the doctrines laid down by the Sung philosophers, seeking to harmonize the different philosophical issues and points of view rather than exploring new horizons.

Literature. Chinese literature also shows conservative tendencies. Poetry composition remained a favourite pastime of the educated class, including the Sinicized scholars of Mongol, Central Asian, and western Asian origins, but no great works or stylistic innovations were created. During the last chaotic decades of the Yüan, some notable poets emerged, such as the versatile Yang Wei-chen and the bold and unconventional Kao Ch'i. Many prose works dealing with contemporary events and persons were written under the Yüan, but these were notable for their content, not their literary merit. Surprisingly harsh criticism and satire against the Mongols and also undisguised Sung loyalism found open expression, presumably because the Mongols were uninterested in what the Chinese wrote in Chinese and, moreover, were mostly unable to read it. Some writers collected rare or interesting and piquant items and transmitted many aspects of Sung culture to future generations. The lament for the refinement and grandeur of the Sung is a constant theme in Yüan writings.

Criticism and satirization of the Mongols

During the early Yüan period the traditional Chinese official historiography was restored under the charge of the Hanlin Academy, which sponsored the compilation of the official dynastic histories of the Sung, Liao, and Chin states conquered by the Mongols and undertook the compilation of the reign chronicles (*shih-lu*) and other governmental compendiums. The major achievement of official historiography was the compilation (1329–33) of the *Ching-shih ta-tien,* a repository of 800 *chüan* (chapters) of official documents and laws, but the text is now lost. Private historiography, especially works on the events of the Sung, fared rather poorly under the Yüan because of the adverse political and intellectual climate. The most distinguished contribution was written by Ma Tuan-lin and titled *Wen-hsien t'ung-k'ao* ("Comprehensive Survey of Literary Remains"). It was an encyclopaedic documentary history of Chinese institutions from the earliest times down to the middle reign of the Nan Sung dynasty.

In urban society a literature in the vernacular language began to flourish, untrammeled by rigid norms of formalistic or ideological orthodoxy. Novels and stories were written for the amusement of a wide-reading public. And dramatic literature reached such a peak in Yüan China that later literary criticism regarded the Yüan as the classical age for operatic arias (*ch'ü,* a word that also means a full opera, with arias and chanted recitativo). The collection *Yüan ch'ü hsüan* ("Selection from Yüan Operas"), with 100 opera librettos, and the storyteller "prompt books" for such dramatized historical romances as *San-kuo* ("Three Kingdoms") give ample evidence for the creativity and vitality of Chinese dramatic literature. This phenomenon may perhaps be considered as evidence that under the Yüan a certain urbanization took place and something like a bourgeoisie emerged, because dramatic literature and colloquial novels found their clientele chiefly among the merchant and artisan classes.

Popular literature

Foreigners, chiefly of Turkic or Persian origin, also contributed to Chinese literature under the Yüan. They wrote poetry and painted in the Chinese way in order to distinguish themselves in fields where they could gain prestige among the educated Chinese. All the foreigners who wrote in Chinese seem to have avoided any reference to their foreign origin or creed. Nothing, in fact, could be more Chinese than their productions. Even foreigners who, like the Persians, came from a country with a considerable literary tradition of its own never attempted to introduce their native forms, subject matter, or religions. No literary symbiosis seemed possible, and, although China was exposed to more external influences under the Yüan than ever before, Chinese literature shows little effect from such contacts with the outside world. It is perhaps symptomatic that under the Yüan no literary works from other civilizations were translated into Chinese and that practically no translations of Chinese Classical and historical works into Mongol have survived. There seemed to be only the alternatives of complete rejection of Chinese civilization, as practiced by most Mongols, or wholesale absorption by Chinese culture. (H.Fr./H.Ch.)

The arts. Conservatism played a dominant role in the arts during the Mongol period. In sponsored arts such as sculpture and ceramics, the Mongols' desire to lay claim to the Chinese Imperial heritage was not complemented by any strong artistic vision of their own, and conservatism meant mere perpetuation. Sung, Liao, and Chin ceramic types were continued, often altered only by increased bulk, while the great artistic achievement of the era, blue-and-white ware, probably derived from non-Imperial sources. Government-sponsored Buddhist sculpture often attained high artistic standards, preserving the realism and powerful expression of T'ang and Sung traditions, while in the finest sculpture of the time, such as the reliefs at the Chüyung Gate north of Ta-tu (1342–45), this was combined with a flamboyant surface decor and striking dramatization better suited to foreign taste than to the increasingly restrained Chinese aesthetic.

Conservatism also tempered the private arts of calligraphy and painting: the scholar-amateurs who produced them felt impelled to preserve their heritage against a perceived barbarian threat. Conservatism, however, often took the form of a creative revival that combed the past for sources of inspiration and then artistically transformed them into a new idiom. In calligraphy, Chao Meng-fu gave new impetus to the 4th-century style of Wang Hsi-chih, which then became a standard for Chinese writing and book printing for centuries. In painting, Chao and his contemporary Ch'ien Hsüan helped to complete the development of a distinctively amateur style that ushered in a new phase in the history of Chinese painting. Their work did not continue that of the previous generation but ranged widely over the available past tradition, and past

Works of Chao Meng-fu

styles rather than observed objects became the subject of artistic interpretation. The naturalism of Sung painting gave way to calligraphically inspired abstractions. Paintings became closely linked in style to the written inscriptions that appeared upon them with increasing frequency and prominence. Skillful professional techniques and overt visual attractiveness were avoided, replaced by deliberate awkwardness and an intellectualized flavour. Their works were done for private purposes, often displaying or concealing personal and political motives, to be understood only by fellow literati through the subtle allusions of their subject matter, stylistic references, or inscriptions.

Naturalistic painting styles also continued in popularity throughout the first two-thirds of the period, painted by such important artists as Li K'an and Jen Jen-fa. Perpetuating northern traditions of the T'ang and Sung periods, these styles were practiced chiefly by scholar-officials associated with the court at the capital. Several members of the Mongol royal family became major patrons or collectors of such conservative styles, although Imperial patronage remained slight in comparison with earlier periods.

In the latter third of the dynasty, with a sharp decline in the practice of painting by scholar-officials and northerners, Yüan painting was increasingly represented by the innovative approach of Chao Meng-fu as practiced by reclusive scholars from the Su-chou–Wu-hsing area. Four of these—the landscape painters Huang Kung-wang, Wu Chen, Ni Tsan, and Wang Meng—transformed and blended certain elements from the past into highly personal, easily recognizable styles and later came to be known as the Four Masters of the Yüan dynasty. In the early Ming period the Hung-wu emperor decimated the Su-chou literati and with it Su-chou painting, but by the end of the 15th century Su-chou artists came once again to dominate Chinese painting, and the styles of the Four Masters became the most influential of all painting models in later Chinese history. (Je.Si.)

The Four Masters of the Yüan dynasty

Yüan China and the West. As mentioned above, Mongol rulers favoured trade in all their dominions. In China, too, they eliminated state trade controls that had existed under the Sung and Chin, so that internal and external trade reached unprecedented proportions. It seems, however, that China's transcontinental trade with the Middle East and Europe was in the hands of non-Chinese (Persians, Arabs, Syrians). Silk, the Chinese export commodity par excellence, reached the Middle East and even Europe via the caravan routes across Asia; Chinese ceramics were also exported, chiefly into the Islāmic countries. The Asian countries concentrated their European trade largely with the Italian republics (*e.g.,* Genoa, Venice). To the Italians, trade with the East was so important that the *Practica della mercatura,* a handbook on foreign trade, included the description of trade routes to China.

Contacts with the Middle East and Europe

Direct contacts between China and Europe were insignificant, however, in spite of China's being a part of an empire stretching from Ta-tu to southern Russia. Chinese historical and geographic literature had little to say about the European parts of the Mongol Empire; in the official dynastic history of the Yüan, references to foreign countries are limited to countries such as Korea, Japan, Nam Viet, Burma, and Champa, with which China had carried on trade or tributary relations for centuries, and there are some scattered data on Russia. For some time a Russian guards regiment existed in Ta-tu, and some Russian soldiers were settled in military colonies in eastern Manchuria. As a whole, however, the civilizations of Europe and China did not meet, although contacts were made easy; Europe remained for the Chinese a vague region somewhere "beyond the Uighur."

More important were the contributions from the Muslim countries of the Middle East, chiefly in the fields of science and technology. During the reign of Kublai Khan, Arab-Persian astronomy and astronomical instruments were introduced into China, and the Chinese astronomer Kuo Shou-ching operated an observatory. Nevertheless, the basic conceptions of astronomy remained Chinese, and no attempt was made to adopt the Middle Eastern mathematical and theoretical framework. Similarly, Middle Eastern physicians and surgeons practiced successfully in China, but Chinese medical theory remained uninfluenced by Western practices. In geography a Chinese world map of the 14th century incorporates Arabic geographical knowledge into the Chinese worldview. It shows not only China and the adjacent countries but also the Middle East, Europe, and Africa; the African continent is already given in its actual triangular shape. But this knowledge probably never spread beyond a limited circle of professional geographers, and it is certain that the Sinocentric world conception continued unchallenged under the Yüan dynasty; no curiosity of what lay beyond the Chinese borders was aroused. For the countries to be reached by sea (such as Southeast Asian countries and India), Chinese works of the Yüan offer only a poor extract from the Sung work *Chu-fan chih* ("Description of the Barbarians") of *c.* 1225.

The situation is different regarding European knowledge of China. The Mongol advance into eastern Europe had given Europeans an acute awareness that actual people lived in regions hitherto shrouded in vague folkloric legends and myths; the Islāmic world had become a reality to Europeans with the first Crusades. It was, therefore, only natural that the Roman Catholic Church looked for potential converts among the obviously non-Muslim people of Asia. After Franciscan envoys brought back information on what was known as Cathay (China) in the mid-13th century, Pope Nicholas IV, a former Franciscan, dispatched a Franciscan mission to the court of the Grand Khan in Ta-tu (known in Europe as Cambaluc). The missionaries formed the nucleus of a Catholic hierarchy on Chinese soil: Cambaluc became the seat of an archbishopric, and in 1323 a bishopric was established in Ch'üan-chou. A famous Franciscan missionary was Odoric of Pordenone, who traveled in China in the 1320s; his reports—together with letters written by other Catholic missionaries—brought firsthand information on China to medieval Europe and today throw some light on the earliest missionary work in China. The Franciscan mission, which had to compete with the Nestorian clergy, was carried on more by the foreigners in China than by the Chinese themselves. The friars preached in Tatar, which means either Mongol or Turkic, and apparently won no Chinese converts. Significantly, no Chinese source mentions the activities of these missionaries; the Chinese probably regarded the Franciscans as one of the many strange, foreign sects, perhaps an outlandish variety of Buddhism. Archaeological evidence of the presence of Europeans and of Roman Catholicism has been discovered only in modern times, in Yang-chou (in present-day Kiangsu), on a Latin tombstone dated 1342 and recording the death of an Italian lady whose name suggests some relation to a Venetian family engaged in trade with Asia.

European knowledge of China

Only the last direct contact between the papal see and Yüan China can be corroborated by both Western and Chinese sources. In 1336 a group of Alani Christians in Ta-tu sent a letter to Pope Benedict XII, who sent John of Marignola with a mission to the Mongol court. The mission reached the summer capital, Shang-tu, in 1342. Chinese sources have recorded the date of its audience as Aug. 19, 1342. The country from where the envoys came is given by the Chinese source as Fu-lang, a Chinese version of the name Farang (Franks), which was used as a general term for Europeans in the Middle East. The arrival of envoys from what must have seemed the end of the world so impressed the court that an artist was commissioned to paint a portrait of the battle horse that Marignola had brought as a present; this portrait was still extant in the 18th century but is now lost. Chinese literati wrote many eulogies on the portrait of the horse; the country of Fu-lang, however, did not interest the Chinese poets, and the whole embassy of Marignola is invariably described in terms that point to an unbroken Sinocentric attitude. Thus, the contact between the pontiff and the Mongol court remained without further consequence. The end of Mongol rule over China and the strong nationalism of the Ming dynasty also doomed the Catholic missions of the 14th century. The reports of Marco Polo, on the other hand, inaugurated for Europe the era of discoveries and created a new vision of the world, with China as a part.

Although China as a separate cultural entity was only

Chinese influence in Asia

realized dimly and gradually in the European West, Chinese influences spread under the Yüan dynasty to other parts of Asia. Chinese medical treatises were translated into Persian, and Persian miniature painting in the 13th and 14th centuries shows many influences of Chinese art. Chinese-type administration and chancellery practices were adopted by various Mongol dominions in Central Asia and the Middle East. It has even been suggested that the invention of gunpowder and of printing in Europe was due to a sort of stimulus diffusion from China, although a direct influence from China cannot be proved.

Chinese civilization itself remained very much what it had been before the Yüan dynasty, with a certain cultural isolationism a distinctive element. Neither the self-image of the Chinese nor China's position in the world changed very drastically. The change and challenges to which China was exposed under the Yüan, however, can explain many of the characteristic traits of Ming history.

The end of Mongol rule. The basic dilemma of Mongol rule in China—the Mongols' inability to achieve a durable identification with Chinese civilian institutions and to modify the military and colonialist character of their rule—became more apparent under Kublai's successors and reached a maximum under Togon-temür, the last Yüan ruler. Togon-temür was not unfriendly toward Chinese civilization, but this could not alter the contempt of many leading Mongols for Chinese civilian institutions. For centuries China had known clique factionalism at court, but this was mostly fought with political means; Mongol factionalism usually resorted to military power. Militarization gradually spread from the Mongol ruling class into Chinese society, and not a few dissatisfied Chinese leaders established regional power based on local soldiery. The central administration, headed by a weak emperor, proved incapable of preserving its supremacy.

Thus, the military character of Mongol rule paved the way for the success of Chinese rebels, some of whom came from the upper class, while others were messianic sectarians who found followers among the exploited peasantry. The Mongol court and the provincial administrations could still rely on a number of faithful officials and soldiers, and so the progress of the rebel movement in the 1350s and 1360s remained slow. But the rebel armies who had chosen what is now Nanking as their base took Ta-tu in 1368; the Mongol emperor fled, followed by the remnants of his overthrown government.

Fall of Ta-tu

The Mongols remained a strong potential enemy of China for the next century, and the Genghis Khan clan in Mongolia continued to regard itself as the legitimate ruler of China. The century of Mongol rule had some undesirable effects upon the government of China—Imperial absolutism and a certain brutalization of authoritarian rule, inherited from the Yüan, were features of the succeeding Ming government. Yet, Mongol rule lifted some of the traditional ideological and political constraints on Chinese society. The Confucian hierarchical order was not rigidly enforced as it had been under the T'ang and Sung, and the Mongols thereby facilitated the upward mobility of some social classes, such as the merchants, and encouraged extensive growth of popular culture, which had been traditionally downgraded by the literati. (H.Fr./H.Ch.)

The Ming dynasty

POLITICAL HISTORY

Ineptitude on the throne, bureaucratic factionalism at court, rivalries among Mongol generals, and ineffective supervision and coordination of provincial and local administration had gravely weakened the Yüan government by the 1340s. And in 1351 disastrous flooding of the Huang and Huai river basins aroused hundreds of thousands of long-oppressed Chinese peasants into open rebellion in northern Anhwei, southern Honan, and northern Hupeh provinces. Capitalizing on the breakdown of Yüan control, rebel movements spread rapidly and widely, especially throughout central China. By the mid-1360s large regional states had been created that openly flouted Yüan authority: Sung in the Huai Basin, under the nominal leadership of a mixed Manichaean-Buddhist secret-society leader named Han Lin-erh; Han in the central Yangtze Valley, under a onetime fisherman named Ch'en Yu-liang; Hsia in Szechwan, under an erstwhile general of the rebel Han regime named Ming Yü-chen; and Wu in the rich Yangtze Delta area, under a former Grand Canal boatman named Chang Shih-ch'eng. A onetime salt trader and smuggler named Fang Kuo-chen had simultaneously established an autonomous coastal satrapy in Chekiang. While Yüan chieftains contended with one another for dominance at the capital, Ta-tu (present-day Peking), and in the North China Plain, these rebel states to the south wrangled for survival and supremacy. Out of this turmoil emerged a new native dynasty called Ming (1368–1644).

The dynasty's founder. Chu Yüan-chang, founder of the new dynasty, came from a family of physiognomists from K'ai-feng who in Yüan times had deteriorated into itinerant tenant farmers in northern Anhwei Province. Orphaned by famine and plague in 1344, young Chu was taken into a small Buddhist monastery near Feng-yang city as a lay novice. For more than three years he wandered as a mendicant through the Huai Basin; then he studied for the Buddhist priesthood in his monastery. In 1352, after floods, rebellions, and Yüan campaigns against bandits had devastated and intimidated the whole region, Chu was persuaded to join a Feng-yang branch of Han Lin-erh's uprising. He quickly made himself the most successful general on the southern front of the rebel Sung regime, and in 1356 he captured and set up his headquarters in Nanking, a populous and strategically located city on the Yangtze River. There he began assembling a rudimentary government and greatly strengthened his military power. Between 1360 and 1367, still nominally championing the cause of the Sung regime, his armies gained control of the vast central and eastern stretches of the Yangtze Valley, absorbing first the Han domain to the west of Nanking and then the Wu domain to the east. He also captured the Chekiang coastal satrap, Fang Kuo-chen. Chu then announced his intention of liberating all China from Mongol rule and proclaimed a new dynasty effective with the beginning of 1368. The dynastic name Ming, meaning "Brightness," reflects the Manichaean influence in the Sung-revivalist Han Lin-erh regime under which Chu had achieved prominence. Chu came to be known by his reign name, the Hung-wu ("Vastly Martial") emperor.

Background of the founding emperor

Vigorous campaigning in 1368 drove the Mongols out of Shantung, Honan, and Shansi provinces and from Ta-tu itself, which was occupied by Ming forces on September 14, and simultaneously extended Ming authority through Fukien and Hunan into Kwangtung and Kwangsi provinces on the south coast. In 1369–70 Ming control was established in Shensi, Kansu, and Inner Mongolia; and continued campaigning against the Mongols thereafter extended northwestward to Ha-mi (1388), northeastward to the Sungari River in Manchuria (1387), and northward into Outer Mongolia beyond Karakorum, almost to Lake Baikal (1387–88). In operations to the west and southwest, Ming forces destroyed the rebel Hsia regime in Szechwan in 1371, wiped out major Mongol and aboriginal resistance in Kweichow and Yunnan in 1381–82, and pacified aboriginal tribesmen on the Sino-Burmese border in 1398. Thus, by the end of the Hung-wu emperor's 30-year reign in 1398, his new dynasty controlled the whole of modern China proper and dominated the northern frontier regions, from Ha-mi through Inner Mongolia and into northern Manchuria.

The dynastic succession. The Ming dynasty, which encompassed the reigns of 16 emperors, proved to be one of the stablest and longest dynasties of Chinese history. Rulers of Korea, Mongolia, East Turkistan, Burma, Siam, and Nam Viet regularly acknowledged Ming overlordship, and at times tribute was received from as far away as Japan, Java and Sumatra, Ceylon and South India, the East African coast, the Persian Gulf region, and Samarkand. Modern Chinese honour the Ming emperors especially for having restored China's international power and prestige, which had been in decline since the 8th century. The Ming emperors probably exercised more far-reaching influence in East Asia than any other native rulers of China, and their attitude toward the representa-

tives of Portugal, Spain, Russia, Britain, and Holland who appeared in China before the end of their dynasty was a condescending one.

Ming reign names

For the first time in Chinese history the Ming rulers regularly adopted only one reign name (*nien-hao*) each; the sole exception was the sixth emperor, who had two reigns separated by an interval of eight years. Because of this reign-name practice, which was perpetuated under the succeeding Ch'ing dynasty, modern writers, confusingly but correctly, refer to the Wan-li emperor, for example, by his personal name, Chu I-chün, or as Ming Shen-tsung, or sometimes, incorrectly but conveniently, simply as Wan-li, as if the reign name were a personal name.

The Ming dynasty's founder, the Hung-wu emperor, was one of the strongest and most colourful personalities of Chinese history. His long reign established the governmental structure, policies, and tone that characterized the whole dynasty. After his death in 1398 his grandson and successor, the Chien-wen emperor, trying to assert control over his powerful uncles, provoked a rebellion on the part of the Prince of Yen and was overwhelmed in 1402. The Prince of Yen took the throne as the Yung-lo emperor (reigned 1402–24) and proved to be vigorous and aggressive. He subjugated Nam Viet, personally campaigned against the reorganizing Mongols in the north, and sent large naval expeditions overseas, chiefly under the eunuch admiral Cheng Ho, to demand tribute from rulers as far away as Africa. He also returned the empire's capital to Peking, giving that city its modern name.

For a century after the Yung-lo emperor, the empire enjoyed stability, tranquillity, and prosperity. But state administration began to suffer from exploitative domination of weak emperors by favoured eunuchs: Wang Chen in the 1440s, Wang Chih in the 1470s and 1480s, and Liu Chin from 1505 to 1510. The Hung-hsi (reigned 1424–25), Hsüan-te (1425–35), and Hung-chih (1487–1505) emperors were, nevertheless, able and conscientious rulers in the Confucian mode. The only serious disruption of the peace occurred in 1449 when the eunuch Wang Chen led the Cheng-t'ung emperor (first reign 1435–49) into a disastrous military campaign against the Oyrat (western Mongols). The Oyrat leader Esen Taiji ambushed the Imperial army, captured the Emperor, and besieged Peking. The Ming defense minister, Yü Ch'ien, forced Esen to withdraw unsatisfied and for eight years dominated the government with emergency powers. When the interim Ching-t'ai emperor (reigned 1449–57) fell ill in 1457, the Cheng-t'ung emperor, having been released by the Mongols in 1450, resumed the throne as the T'ien-shun emperor (1457–64). Yü Ch'ien was executed as a traitor.

Conflict with the western Mongols

The Cheng-te (reigned 1505–21) and Chia-ching (1521–1566/67) emperors were among the less esteemed Ming emperors. The former was an adventure-loving carouser, the latter a lavish patron of Taoist alchemists. For one period of 20 years, during the regime of an unpopular grand secretary named Yen Sung, the Chia-ching emperor withdrew almost entirely from governmental cares. Both emperors cruelly humiliated and punished hundreds of officials for their temerity in remonstrating.

China's long peace ended in the Chia-ching emperor's reign. The Oyrat, under the vigorous new leadership of Altan Khan, were a constant nuisance on the northern frontier from 1542 on; in 1550 Altan Khan raided the suburbs of Peking itself. During the same era Japan-based sea raiders repeatedly plundered China's southeastern coast. Such sea raiders, a problem in Yüan times and from the earliest Ming years, had been suppressed in the reign of the Yung-lo emperor, when the Ashikaga shogunate offered nominal submission to China in exchange for generous trading privileges. But eventually changes in the official trade system provoked new discontent along the coast, and during the 1550s corsair fleets looted the Shanghai–Ning-po region almost annually, sometimes sending raiding parties far inland to terrorize cities and villages throughout the whole Yangtze Delta. Although coastal raiding was not totally suppressed, it was brought under control in the 1560s. Also in the 1560s Altan Khan was repeatedly defeated, so that he made peace in 1571. For the next decade, during the last years of the Lung-ch'ing emperor (reigned 1566/67–1572) and the early years of the Chia-ching emperor (1572–1620), there was a high level of governmental stability. The court was dominated by the outstanding grand secretary of Ming history, Chang Chü-cheng, and capable generals such as Ch'i Chi-kuang restored and maintained effective military defenses.

In 1592, when Japanese forces under Toyotomi Hideyoshi invaded Korea, Ming China was still strong and responsive enough to campaign effectively in support of its tributary neighbour. But the Korean war dragged on indecisively until 1598, when Hideyoshi died and the Japanese withdrew. It made heavy demands on Ming resources and apparently precipitated a military decline in China.

The reign of the Wan-li emperor was a turning point of Ming history in other regards as well. Partisan wrangling among civil officials had flared up in the 1450s in reaction to Yü Ch'ien's dominance and again in the 1520s during a prolonged "rites controversy" provoked by the Chia-ching emperor on his accession; after Chang Chü-cheng's death in 1582, it became the normal condition of court life. Through the remainder of the Wan-li emperor's long reign a series of increasingly vicious partisan controversies absorbed the energies of officialdom, while the harassed emperor abandoned more and more of his responsibilities to eunuchs. The decline of bureaucratic discipline and morale continued under the T'ai-ch'ang emperor, whose sudden death after a reign of only one month in 1620 fueled new conflicts. The T'ien-chi emperor (reigned 1620–27) was too young and indecisive to provide needed leadership. In 1624 he finally gave almost totalitarian powers to his favourite, Wei Chung-hsien, the most notorious eunuch of Chinese history. Wei brutally purged hundreds of officials, chiefly those associated with a reformist clique called the Tung-lin party, and staffed the government with sycophants.

The threat from the Manchu

A new threat had meantime appeared on the northern frontier. The Manchu, quiet occupants of far eastern Manchuria from the beginning of the dynasty, were aroused in 1583 by an ambitious young leader named Nurhachi. During the Wan-li emperor's latter years they steadily encroached on central Manchuria. In 1616 Nurhachi proclaimed a new dynasty, and overwhelming victories over Ming forces in 1619 and 1621 gave him control of the whole northeastern segment of the Ming Empire, down to the Great Wall at Shan-hai-kuan.

The Ch'ung-chen emperor (reigned 1627–44) tried to revitalize the deteriorating Ming government. He banished Wei Chung-hsien but could not quell the partisan strife that was paralyzing the bureaucracy. The Manchu repeatedly raided within the Great Wall, even threatening Peking in 1629 and 1638. Taxes and conscriptions became more and more oppressive to the Chinese population, and banditry and rebellions spread in the interior. The Ming government became completely demoralized. Finally, a domestic rebel named Li Tzu-ch'eng captured the capital in April 1644, and the Ch'ung-chen emperor committed suicide. The Ming commander at Shan-hai-kuan accepted Manchu help in an effort to punish Li Tzu-ch'eng and restore the dynasty, only to have the Manchu seize the throne for themselves.

Ming loyalists ineffectively resisted the Manchu Ch'ing dynasty from various refuges in the south for a generation. Their so-called Nan (Southern) Ming dynasty principally included the Prince of Fu (Chu Yu-sung, reign name Hung-kuang), the Prince of T'ang (Chu Yü-chien, reign name Lung-wu), the Prince of Lu (Chu I-hai, no reign name), and the Prince of Kuei (Chu Yu-lang, reign name Yung-li). The loyalist coastal raider Cheng Ch'eng-kung (Koxinga) and his heirs held out on Taiwan until 1683.

GOVERNMENT AND ADMINISTRATION

Local government. The Ming state system was built upon a foundation of institutions inherited from the T'ang and Sung dynasties and modified by the intervening dynasties of conquest from the north, especially the Yüan. The distinctive new patterns of social and administrative organization that emerged in Ming times persisted, in their essential features, through the Ch'ing dynasty into the 20th century.

Social organization

At local and regional levels the traditional modes and personnel of government were perpetuated in ad hoc fashion in the earliest Ming years, but as the new empire became consolidated and stabilized, highly refined control structures were imposed that—in theory and probably also in reality—eventually subjugated all Chinese to the throne to an unprecedented and totalitarian degree. The Ming law code, promulgated in final form in 1397, reinforced the traditional authority and responsibility of the paterfamilias, considered the basis of all social order. Each family was classified according to hereditary status, the chief categories being civilian, military, and artisan; and neighbouring families of the same category were organized into groups, for purposes of self-government and mutual help and surveillance. Civilians were grouped in "tithings" of 10 families, and these, in turn, were grouped in "communities" totaling 100 families, plus 10 additional prosperous households, which in annual rotation provided community chiefs who were intermediaries between the citizenry at large and the formal agencies of government. This system of social organization, called *li-chia* (later replaced by or coexistent with a local defense system called *pao-chia*), served to stabilize, regulate, and indoctrinate the populace under relatively loose formal state supervision.

As in earlier times, formal state authority at the lowest level was represented by court-appointed magistrates of districts (*hsien*), and each cluster of neighbouring districts was subordinate to a supervisory prefecture (*fu*) normally governed from and dominated by a large city. Government at the modern provincial (*sheng*) level, after beginnings in Yüan times, was now regularized as an intermediary between the prefectures and the central government. There were 13 Ming provinces, each as extensive and populous as modern European states: Shantung, Honan, Shansi, Shensi (incorporating modern Kansu), Szechwan, Hukuang (comprising modern Hupeh and Hunan), Kiangsi, Chekiang, Fukien, Kwangtung, Kwangsi, Kweichow, and Yunnan. Nam Viet was a 14th province from 1407 to 1428. The large regions dominated by the great cities Peking (in modern Hopeh) and Nanking (in modern Kiangsu and Anhwei) were not subordinated to provincial-level governments but for administrative supervision were "directly attached" (*chih-li*) to the capital establishments in those cities; they are normally referred to as the northern and southern metropolitan areas (Pei Chih-li and Nan Chih-li). Nanking was the Ming capital through 1420. Thereafter Peking was the capital, but Nanking retained special status as auxiliary capital.

Ming provincial governments consisted of three coordinate agencies with specialized responsibilities for general administration, surveillance and judicial affairs, and military affairs. These were the channels for routine administrative contacts between local officials and the central government.

Central government. In its early form the Ming central government was dominated by a unitary Secretariat. The senior executive official of the Secretariat served the emperor as a chief counselor, or prime minister. Suspected treason on the part of the chief counselor Hu Wei-yung in 1380 caused the Hung-wu emperor to abolish all executive posts in the Secretariat, thus fragmenting general administration authority among the six functionally differentiated, formerly subordinate ministries of Personnel, Revenue, Rites, War, Justice, and Works. This effective abolition of the Secretariat left the emperor as the central government's sole coordinator of any significance, strengthened his control over the officialdom, and, in the view of many later scholars, gravely weakened the Ming state system.

Especially prominent among other agencies of the central government was a Censorate, which was charged with the dual functions of maintaining disciplinary surveillance over the whole of officialdom and remonstrating against unwise state policies and improprieties in the conduct of the emperor. Equally prominent were five chief military commissions, each assigned responsibility, jointly with the Ministry of War, for a geographically defined segment of the empire's military establishment. There was originally a unitary Chief Military Commission paralleling the Secretariat, but in the 1380s its authority was similarly fragmented. The hereditary soldiers, who were under the administrative jurisdiction of the chief military commissions, originated as members of the rebel armies that established the dynasty, as surrendering enemy soldiers, in some instances as conscripts, or as convicted criminals. They were organized and garrisoned, principally along the frontiers, near the capital, or in other strategic places, but also throughout the interior, in units called guards and battalions. Whenever possible, such units were assigned state-owned agricultural lands so that, by alternating military duties with farm labour, the soldiers could be self-supporting. The military families, in compensation for providing soldiers in perpetuity, enjoyed exemptions from labour services levied by the state on civilian families. Each guard unit reported to its Chief Military Commission at the capital through a provincial-level Regional Military Commission. Soldiers from local guards were sent in rotation to the capital for special training or to the Great Wall or another area of comparable military importance for active patrol and guard duty. At such times, as on large-scale campaigns, soldiers served under tactical commanders who were on ad hoc duty assignments, detached from their hereditary posts in guard garrisons or higher echelons of the military service.

Military organization

Later innovations. In the 15th century new institutions were gradually devised to provide needed coordination both in the central government and in regional administration. Later emperors found the Hung-wu emperor's system of highly centralized power and fragmented government structure inefficient and inconvenient. Litterateurs of the traditional and prestigious Hanlin Academy came to be assigned to the palace as secretarial assistants, and they quickly evolved into a stable Grand Secretariat (Nei-ko) through which emperors guided and responded to the ministries and other central government agencies. Similarly, the need for coordinating provincial-level affairs led to the delegation of high-ranking central government dignitaries to serve as regional commanders (*tsung-ping kuan*) and governor-like grand coordinators (*hsün-fu*) in the provinces. Finally, clusters of neighbouring provinces came under the supervisory control of still more prestigious central government officials, known as supreme commanders (*tsung-tu*), whose principal function was to coordinate military affairs in extended, multiprovince areas. As the dynasty grew older, as the population expanded, and as administration became increasingly complex, coordinators proliferated even at subprovincial levels in the form of circuit intendants (*tao-t'ai*), who were delegated from provincial agencies as functionally specialized intermediaries with prefectural administrations.

Examinations for civil service

To an extent unprecedented except possibly in Sung times, Ming government was dominated by nonhereditary civil service officials recruited on the basis of competitive written examinations. Hereditary military officers, although granted ranks and stipends higher than their civil service counterparts and eligible for noble titles rarely granted to civil officials, always found themselves subordinate to policymaking civil servants except in the very early years of the dynasty. Members of the Imperial clan, except in the earliest and latest years of the dynasty, were forbidden to take active part in administration, and the Ming practice of finding Imperial consorts in military families effectively denied Imperial in-laws access to positions of significant authority. High-ranking civil officials usually could place one son each in the civil service by hereditary right, and, beginning in 1450, wealthy civilians often were able to purchase nominal civil service status in government fund-raising drives. But those entering the service in such irregular ways rarely had notable, or even active, careers in government. In the early decades of the dynasty, before competitive examinations could provide sufficient numbers of trustworthy men for service, large numbers of officials were recruited directly from government schools or through recommendations by existing officials; and such recruits often rose to eminence. But after about 1400, persons entering the civil service by avenues other than examinations had little hope for successful careers.

In a departure from traditional practices but in accordance with the Yüan precedent, there was only one type

of examination given in Ming times. It required a general knowledge of the Classics and history and the ability to relate Classical precepts and historical precedents to general philosophical or specific political issues. As in Yüan times, interpretations of the Classics by the Chu Hsi school of Neo-Confucianism were prescribed. By the end of the Ming dynasty the writing of examination responses had become highly stylized and formalized in a pattern called "the eight-legged essay" (*pa-ku-wen*), which in subsequent centuries became notoriously repressive of creative thought and writing.

Local schools

Beginning in the Hung-wu emperor's reign, the government sponsored district-level schools, in which state-subsidized students prepared for the civil service examinations. Especially talented students could be promoted from such local schools into programs of advanced learning and probationary service at a National University in the capital. Especially after 1500 there was a proliferation of private academies in which scholars gathered to discuss philosophy and students were also prepared for the examinations. Education intendants from provincial headquarters annually toured all localities, examining candidates who presented themselves and certifying those of "promising talent" (*hsiu-ts'ai*) as being qualified to undertake week-long examination ordeals that were conducted every third year at the provincial capitals. Those who passed the provincial examinations (*chü-jen*) could be appointed directly to posts in the lower echelons of the civil service. They were also eligible to compete in triennial metropolitan examinations conducted at the national capital. Those who passed were given degrees often called doctorates (*chin-shih*) and promptly took an additional palace examination, nominally presided over by the emperor, on the basis of which they were ranked in order of excellence. They were registered as qualified officials by the Ministry of Personnel, which assigned them to active-duty posts as vacancies occurred. While on duty they were evaluated regularly by their administrative superiors and irregularly by touring inspectors from the Censorate. It was normally only after long experience and excellent records in low- and middle-grade posts, both in the provinces and in the capital, that an official might be nominated for high office and appointed by personal choice of the emperor.

Although acceptance into, and success in, the civil service were the most highly esteemed goals for all and were nominally determined solely by demonstrated scholastic and administrative abilities, other factors inevitably intruded to prevent the civil service system from being wholly "open." Differences in the economic status of families made for inequalities of educational opportunity and, consequently, inequalities of access to civil service careers. The sons of well-to-do families clearly had advantages, and men of the affluent and cultured southeastern region so threatened to monopolize scholastic competitions that regional quotas for passers of the metropolitan examinations were imposed by the government, beginning in 1397. Once in the service one's advancement or even survival often depended on shifting patterns of favouritism and factionalism. Modern scholarship strongly suggests, nevertheless, that "new blood" was constantly entering the Ming civil service, that influential families did not monopolize or dominate the service, and that men regularly rose from obscurity to posts of great esteem and power on the basis of merit. Social mobility, as reflected in the Ming civil service, was very possibly greater than in Sung times and was clearly greater than in the succeeding Ch'ing era.

Weaknesses of Ming government

The Ming pattern of government has generally been esteemed for its stability under civil service dominance, its creativity in devising new institutions to serve changing needs, and its suppression of separatist warlords on one hand and disruptive interference by Imperial clansmen and palace women on the other. It suffered, however, from sometimes vicious factionalism among officials, from recurrences of abusive influence on the part of palace eunuchs, and from defects in its establishment of hereditary soldiers. The military system not only failed to achieve self-support but stagnated steadily, so that from the mid-15th century onward it had to be supplemented by conscripts and, finally, all but replaced by mercenary recruits. Most notoriously, the Ming state system allowed emperors to behave capriciously and abusively toward their officials. Despite their high prestige, officials had to accept being ignored, humiliated, dismissed, or subjected to bodily punishment and to risk being cruelly executed (sometimes in large numbers), as suited the Imperial fancy. Power was concentrated in the hands of the Ming emperors to a degree that was probably unparalleled in any other long-lived dynasty of Chinese history, and the Ming emperors often exercised their vast powers in abusive fashion.

FOREIGN RELATIONS

Whereas in Ming times the Chinese organized themselves along wholly bureaucratic and tightly centralized lines, the Ming emperors maintained China's traditional feudal-seeming relationships with foreign peoples. These included the aboriginal tribes of south and southwest China, who often rose in isolated rebellions but were gradually being assimilated. The Chinese took for granted that their emperor was everyone's overlord and that de facto (mostly hereditary) rulers of non-Chinese tribes, regions, and states were properly his feudatories. Foreign rulers were thus expected to honour and observe the Ming ritual calendar, to accept nominal appointments as members of the Ming nobility or military establishment, and, especially, to send periodic missions to the Ming capital to demonstrate fealty and present tribute of local commodities. Tributary envoys from continental neighbours were received and entertained by local and provincial governments in the frontier zones. Those from overseas were welcomed by special maritime trade supervisorates (*shih-po ssu,* often called offices of trading ships) at three key ports on the southeast and south coasts: Ning-po in Chekiang (for Japanese contacts), Ch'üan-chou in Fukien (for contacts with Taiwan and the Ryukyu Islands), and Canton in Kwangtung (for contacts with Southeast Asia). The frontier and coastal authorities forwarded foreign missions to the national capital, where the Ministry of Rites offered them hospitality and arranged for their audiences with the emperor. All envoys received valuable gifts in acknowledgement of the tribute they presented. They also were permitted to buy and sell private trade goods at specified, officially supervised markets, both in the capital and on the coasts and frontiers. Thus, copper coins and luxury goods (notably silks and porcelains) flowed out of China, and pepper, other spices, and similar rarities flowed in. On the western and northern frontiers the principal exchange was in Chinese tea and steppe horses. On balance, the combined tribute and trade activities were highly advantageous to foreigners—so much so that the Chinese early established limits for the size and cargoes of foreign missions and prescribed long intervals that must elapse between missions.

Aims of foreign policy

The principal aim of Ming foreign policy was political: to maintain China's security and, especially, to make certain the Mongols could not threaten China again. To this end the Hung-wu emperor repeatedly sent armies northward and northwestward to punish resurgent Mongol groups and prevent any reconsolidation of Mongol power. The Yung-lo emperor was even more zealous: he personally campaigned into the Gobi (desert) five times, and his transfer of the national capital from Nanking to Peking, completed in 1421 after long preparations, was largely a reflection of his concern about the frontier. His successors, though less zealous than he in this regard, were vigilant enough so that the Great Wall was restored and expanded to its present-day extent and dimensions. Frontier defense forces, aligned in nine defense commands stretching from Manchuria to Kansu, kept China free from Mongol incursions, except for occasional raiding forays such as those by Esen Taiji and Altan Khan.

The fact that the Mongols could not reunite themselves was a fortunate circumstance for Ming China. As early as the Yung-lo emperor's time the Mongols were divided into three groups that were often antagonistic to one another. They were the so-called western Mongols or Oyrat (also known as Eleuthes, Kalmycks, or Dzungar), the eastern Mongols or Tatars, and a group in the Ch'engte area known as the Urianghad tribes. The Urianghad tribes surrendered to the Hung-wu emperor and were in-

corporated into China's frontier defense system under a Chinese military headquarters. Because they served the Yung-lo emperor as a loyal rear guard during his seizure of the throne, he rewarded them with virtual autonomy, withdrawing the Chinese command post from their homeland beyond the Great Wall. Subsequently, the Hsüan-te emperor similarly withdrew the command post that the Hung-wu emperor had established at the Mongols' old extramural capital, Shang-tu. These withdrawals isolated Manchuria from China proper, terminated active Chinese military control in Inner Mongolia, and exposed the Peking area in particular to the possibility of probing raids from the nearby steppes. They reflected an essentially defensive Chinese posture in the north, which by late Ming times allowed the Oyrat to infiltrate and dominate Ha-mi and other parts of the northwestern frontier, and the Manchu to rise to power in the northeast.

As for foreign peoples other than the Mongols, the Ming attitude was on the whole unaggressive: so long as they were not disruptive, the Ming emperors left them to themselves. The Hung-wu emperor made this his explicit policy. Even though he threatened the Japanese with punitive expeditions if they persisted in marauding along China's coasts, he dealt with the problem by building strong fortresses and coastal-defense fleets that successfully repulsed the marauders. He did send an army to subdue T'u-lu-p'an in 1377 when the Turko-Mongol rulers of that oasis region rebelled and broke China's traditional transport routes to the west. But he refused to intervene in dynastic upheavals in Nam Viet and Korea (where the Koryŏ fell to the Yi), and he was unmoved by the rise of the Turko-Mongol empire of Timur in the far west at Samarkand, even though Timur murdered Chinese envoys and planned to campaign against China.

Tribute-collecting voyages of the Yung-lo emperor's reign

The Yung-lo emperor was much more aggressive. He sent the eunuch admiral Cheng Ho on tribute-collecting voyages into Southeast Asia, the Indian Ocean, the Persian Gulf, and as far as East Africa. On one early voyage Cheng Ho intervened in a civil war in Java and established a new king there; on another, he captured the hostile king of Ceylon and took him prisoner to China. The Yung-lo emperor also reacted to turbulence in Nam Viet by sending an expeditionary force that incorporated the area into the Ming domain as a province in 1407.

After the Yung-lo era the Ming government reverted to the founding emperor's unaggressive policy toward foreign states. Nam Viet was abandoned in 1428 after protracted guerrilla-style resistance had thoroughly undermined Chinese control there. A new civil war in Nam Viet provoked the Chinese, after long and agonized discussion, to prepare to intervene there again in 1540; but the offer of ritual submission by a usurper gave the Chinese an opportunity to avoid war, and they welcomed it. On only two other occasions were Ming military forces active outside China's borders: in 1445–46 when Chinese troops pursued a rebellious border chief into Burma despite Burmese resistance, and in 1592–98 when the Ming court undertook to help Chosŏn (Korea under the Yi dynasty) repulse Japanese invaders, in a long and costly effort.

In order to preserve the government's monopolistic control of foreign contacts and trade, and, at least in part, to keep the Chinese people from being contaminated by "barbarian" customs, the Ming rulers prohibited private dealings between Chinese and foreigners and forbade any private voyaging abroad. The rules were so strict as to disrupt even coastal fishing and trading, on which large populations in the south and southeast had traditionally depended for their livelihood. Such unrealistic prohibitions were unpopular and unenforceable, and from about the mid-15th century Chinese readily collaborated with foreign traders in widespread smuggling, for the most part officially condoned. By late Ming times, also, thousands of venturesome Chinese had migrated to become mercantile entrepreneurs in the various regions of Southeast Asia and even in Japan. In efforts to enforce its laws the Ming court closed all maritime trade supervisorates except the one at Canton early in the 16th century, and by the 1540s it had begun to reinvigorate coastal defenses against marauders throughout the southeast and the south.

These circumstances shaped the early China coast experiences of the Europeans, who first appeared in Ming China in 1514. The Portuguese had already established themselves in southern India and at Malacca, where they learned of the huge profits that could be made in the regional trade between the China coast and Southeast Asia. Becoming involved in what the Ming court considered smuggling and piracy, the Portuguese were not welcomed to China; but they would not be rebuffed and by 1557 had taken control of a settlement at the walled-off end of a coastal peninsula (modern Macau) and were trading periodically at nearby Canton. In 1575 Spaniards from Manila visited Canton in a vain effort to get official trading privileges, and soon they were developing active though illegal trade on the Kwangtung and Fukien coasts. Representatives of the Dutch East India Company, after unsuccessfully trying to capture Macau from the Portuguese in 1622, took control of coastal Taiwan in 1624 and began developing trade contacts in nearby Fukien and Chekiang provinces. In 1637 a squadron of five English ships shot its way into Canton and disposed of its cargoes there. Russia, meanwhile, had sent peaceful missions overland to Peking, and by the end of the Ming dynasty the Russians' eastward expansion across Siberia had carried them finally to the shores of the Pacific north of the Amur River.

Missionary activities

Christian missionaries from Europe were handicapped by the bad reputation their trader countrymen had acquired in China, but the Jesuit tactic of accommodating to local customs eventually got the Jesuits admitted to the mainland. Matteo Ricci was the successful pioneer, beginning his work in 1583 well trained in the Chinese language and acquainted with Confucian learning. By the time of his death in 1610, despite hostility in some quarters, Jesuit communities were established in many cities of south and central China, a church had been built in Peking under Imperial patronage, and Christianity was known and respected by many Chinese scholar-officials. Before the end of the dynasty, Jesuits had won influential converts at court (notably the grand secretary Hsü Kuang-ch'i, or Paul Hsü), had produced Chinese books on European science as well as theology, and were manufacturing Portuguese-type cannon for Ming use against the Manchu. They also held official appointments in China's Directorate of Astronomy, which had the important responsibility of determining the official calendar. Both European technology and European ideas were beginning to have some effect on China, albeit still very limited.

ECONOMIC POLICY AND DEVELOPMENTS

Population. Ming China's northward orientation in foreign relations was accompanied by a flow of Chinese migrants from the crowded South back into the vast North China Plain, and by a concomitant shift in emphasis from an urban and commercial way of life back to a rural and agrarian pattern. Thus, demographic and economic trends that had characterized China for centuries—the southward movement of population and the urbanization and commercialization of life—were arrested or even reversed.

Migration to the North

The North China Plain had been neglected since early Sung times, and its rehabilitation became a high-priority project of the early Ming emperors. The Ming founder's ancestral home was in the North, and his son, the Yung-lo emperor, won the throne from a personal power base in the newly recovered North at Peking. Securing the northern frontier was the major political goal of both these emperors, and both had reasons for being somewhat suspicious of Southerners and hostile toward them. In consequence, both emperors regularly moved well-to-do city dwellers of the Yangtze Delta region to northern towns for their cultural adornment, resettled peasants from the overpopulated southeast into the vacant lands of the North for their agrarian redevelopment, and instituted water-control projects to restore the productivity of the Huang and Huai river basins. (Notable among these were rehabilitation and extension of the Grand Canal, which reopened in 1415.) Colonists were normally provided with seeds, tools, and animals and were exempted from taxes for three years. The numerous army garrisons that were stationed in the North for defense of the frontier and of the

post-1420 capital at Peking were also given vacant lands to develop and were encouraged to become self-supporting. Such government measures were supplemented, following political reunification, by popular migration into the relatively frontier-like and open North. Rehabilitation of the North was no doubt also facilitated by the new availability of sorghum for dry farming. All these elements produced a substantial revival of the North. In Yüan times censuses credited the northern provinces with only one-tenth of the total Chinese population, but by the late 16th century they claimed 40 percent of the registered total; and until the late Ming years they were productive enough to sustain themselves as well as most of the large frontier defense forces. Suspension of government incentives late in the 15th century caused the northwest to enter into agrarian decline, and Shensi eventually became impoverished and bandit-infested. Support of the frontier defenses became an increasing burden on the central government.

During the migrations back to the North, the registered populations of the largest urban centres of the southeast declined. For example, between 1393 and 1578 Nanking declined from 1,193,000 to 790,000; Chekiang Province from 10,487,000 to 5,153,000; and Kiangsi Province from 8,982,000 to 5,859,000. Despite this leveling trend in the regional distribution of population, the South, and especially the southeast, remained the most populous, the wealthiest, and the most cultured area of China in Ming times. Such great southeastern cities as Nanking, Su-chou, and Hang-chou remained the major centres of trade and manufacturing, of entertainment, and of scholarship and the arts. Peking was their only rival in the North—solely because of its being the centre of political power.

Population changes

Although official census figures suggest that China's overall population remained remarkably stable in Ming times at a total of about 60,000,000, modern scholars have estimated that there was, in fact, substantial growth, probably to a total well over 100,000,000 and perhaps almost as high as 150,000,000 in the early 17th century. Domestic peace and political stability in the 15th century clearly set the stage for great general prosperity in the 16th century. This can be accounted for in part as the cumulative result of the continuing spread of early ripening rice and of cotton production—new elements that had been introduced into the Chinese economy in Sung and Yüan times. The introduction in the 16th century of food crops originating in America—peanuts (groundnuts), corn (maize), and sweet potatoes—created an even stronger agrarian basis for rapidly escalating population growth in the Ch'ing period.

Agriculture. Neofeudal land-tenure developments of late Sung and Yüan times were arrested with the establishment of the Ming dynasty. Great landed estates were confiscated by the government, fragmented, and rented out; and private slavery was forbidden. In the 15th century, consequently, independent peasant landholders dominated Chinese agriculture. But the Ming rulers were not able to provide permanent solutions for China's perennial land-tenure problems. As early as the 1420s the farming population was in new difficulties despite repeated tax remissions and other efforts to ameliorate its condition. Large-scale landlordism gradually reappeared, as powerful families encroached upon the lands of poor neighbours. Sung-style latifundia do not seem to have reemerged, but by the late years of the dynasty, sharecropping tenancy was the common condition of millions of peasants, especially in central and southeastern China—and a new gulf had opened between the depressed poor and the exploitative rich. The later Ming government issued countless pronouncements lamenting the plight of the common man but never undertook any significant reform of land-tenure conditions.

Taxation. The Ming laissez-faire policy in agrarian matters had its counterpart in fiscal administration. The Ming state took the collection of land taxes—its main revenues by far—out of the hands of civil service officials and entrusted this responsibility directly to well-to-do family heads in the countryside. Each designated tax captain was, on the average, responsible for tax collections in an area for which the land-tax quota was 10,000 piculs (one picul = 107 litres) of grain. In collaboration with the *li-chia* community chiefs of his fiscal jurisdiction, he saw to it that tax grains were collected and then delivered, in accordance with complicated instructions: some to local storage vaults under control of the district magistrate, and some to military units, which, by means of the Grand Canal, annually transported more than 3,000,000 piculs northward to Peking. In the early Ming years venal tax captains seem to have been able to amass fortunes by exploiting the peasantry. Later, however, tax captains normally faced certain ruin because tax-evading manipulations by large landlords thrust tax burdens increasingly on those least able to pay and forced tax captains to make up deficiencies in their quotas out of their personal reserves.

Collection of land taxes

The land-tax rate was highly variable, depending not on the productivity of any plot but on the condition of its tenure, which might be as freehold or as one of several categories of land rented from the government. The land tax was calculated together with labour levies, or corvée, which, though nominally assessed against persons, were assessed against land in normal practice. Corvée obligations also varied widely and were usually payable in paper money or in silver rather than in actual service. Assessments against a plot of land might include several other considerations as well, so that a farmer's tax bill was a complicated reckoning of many different tax items. Efforts to simplify land-tax procedures in the 16th century, principally initiated by conscientious local officials, culminated in the universal promulgation of a consolidated-assessment scheme called "a single whip" (*i-t'iao-pien*) in 1581. Its main feature was the reduction of land tax and corvée obligations to a single category of payment in bulk silver or its grain equivalent. This reform was little more than a bookkeeping change at best, and it was not universally applied. Land-tax inequities were unaffected, and assessments rose sharply and repeatedly from 1618 to meet spiraling costs of defense.

Other revenues

Many revenues other than land taxes contributed to support of the government. Some, such as mine taxes and levies on marketplace shops and vending stalls, were based on proprietorship; others, such as salt taxes, wine taxes, and taxes on mercantile goods in transit, were based on consumption. Of all state revenues, more than half always seem to have remained in local and provincial granaries and treasuries; and of those forwarded to the capital, about half seem normally to have disappeared into the emperor's personal vaults. Revenues at the disposal of the central government were always relatively small. Prosperity and fiscal caution had resulted in the accumulation of huge surpluses by the 1580s, both in the capital and in many provinces; but thereafter the Sino-Japanese war in Chosŏn, unprecedented extravagances on the part of the long-lived Wan-li emperor, and defense against domestic rebels and the Manchu bankrupted both the central government and the Imperial household.

Coinage. Copper coins were used throughout the Ming dynasty. Paper money was used for various kinds of payments and grants by the government, but it was always nonconvertible and, consequently, lost value disastrously. It would, in fact, have been utterly valueless except that it was prescribed for the payment of certain types of taxes. The exchange of precious metals was forbidden in early Ming times, but gradually bulk silver became common currency, and after the mid-16th century government accounts were reckoned primarily in taels (ounces) of silver. By the end of the dynasty silver coins produced in Mexico, introduced by Spanish sailors based in the Philippines, were becoming common on the south coast.

Because during the last century of the Ming dynasty there emerged a genuine money economy, and because concurrently there developed some relatively large-scale mercantile and industrial enterprises under private as well as state ownership (most notably in the great textile centres of the southeast), some modern scholars have considered the Ming age one of "incipient capitalism" from which European-style mercantilism and industrialization might have evolved had it not been for the Manchu conquest and expanding European imperialism. It would seem clear, however, that private capitalism in Ming times flourished only insofar as it was condoned by the state, and it was

never free from the threat of state suppression and confiscation. State control of the economy—for that matter, of society in all its aspects—remained the dominant characteristic of Chinese life in Ming times as earlier.

CULTURE

Role of the state in intellectual life

The predominance of state power also marked the intellectual and aesthetic life of Ming China. By requiring use of their interpretations of the Classics in education and in the civil service examinations, the state prescribed the Neo-Confucianism of the great Sung thinkers Ch'eng I and Chu Hsi as the orthodoxy of Ming times; by patronizing or commandeering craftsmen and artists on a vast scale, it set aesthetic standards for all the minor arts, for architecture, and even for painting; and by sponsoring great scholarly undertakings and honouring practitioners of traditional literary forms, the state established norms in these realms as well. It has consequently been easy for historians of Chinese culture to categorize the Ming era as an age of bureaucratic monotony and mediocrity. But the stable, affluent Ming society, in fact, proved irrepressibly creative and iconoclastic. Drudges by the hundreds and thousands may have been content with producing second-rate imitations or interpretations of T'ang and Sung masterpieces in all genres, but independent thinkers, artists, and writers were striking out in many new directions. The final Ming century, especially, was a time of intellectual and artistic ferment akin to the most seminal ages of the past.

Philosophy and religion. Taoism and Buddhism by Ming times had declined into ill-organized popular religions, and what organization they had was regulated by the state. State espousal of Chu Hsi thought, and state repression of noted early Ming litterateurs, such as the poet Kao Ch'i and the thinker Fang Hsiao-ju, made for widespread philosophical conformity during the 15th century. This was perhaps best characterized by the scholar Hsüeh Hsüan's insistence that the Way had been made so clear by Chu Hsi that nothing remained but to put it into practice. Philosophical problems about man's identity and destiny, however, especially in an increasingly autocratic system, rankled in many minds; and new blends of Confucian, Taoist, and Buddhist elements appeared in a sequence of efforts to find ways of personal self-realization in contemplative, quietistic, and even mystical veins. These culminated in the antirationalist individualism of the famed scholar-statesman Wang Yang-ming, who denied the external "principles" of Chu Hsi and advocated striving for wisdom through cultivation of the innate knowledge of one's own mind and attainment of "the unity of knowledge and action." Wang's followers carried his doctrines to extremes of self-indulgence, preached to the masses in gatherings resembling religious revivals, and collaborated with so-called mad Ch'an Buddhists to spread the notion that Confucianism, Taoism, and Buddhism are equally valid paths to the supreme goal of individualistic self-fulfillment. Through the 16th century intense philosophical discussions were fostered, especially in rapidly multiplying private academies (*shu-yüan*). Rampant iconoclasm climaxed with Li Chih, a zealous debunker of traditional Confucian morality, who abandoned a bureaucratic career for Buddhist monkhood of a highly unorthodox type. Excesses of this sort provoked occasional suppressions of private academies, occasional persecutions of heretics, and sophisticated counterarguments from traditionalistic, moralistic groups of scholars, such as those associated with the Tung-lin Academy near Su-chou, who blamed the late Ming decline of political efficiency and morality on widespread subversion of Chu Hsi orthodoxy. The zealous searching for personal identity was only intensified, however, when the dynasty finally collapsed.

Fine arts. In the realm of the arts, the Ming period has long been esteemed for the variety and high quality of its state-sponsored craft goods—cloisonné and, particularly, porcelain wares. The sober, delicate monochrome porcelains of the Sung dynasty were now superseded by rich, decorative polychrome wares. The best known of these are of blue-on-white decor, which gradually changed from floral and abstract designs to a pictorial emphasis. From this eventually emerged the "willow-pattern" wares that became export goods in great demand in Europe. By late Ming times, perhaps because of the unavailability of the imported Iranian cobalt that was used for the finest blue-on-white products, more flamboyant polychrome wares of three and even five colours predominated. Painting—chiefly portraiture—followed traditional patterns under Imperial patronage, but independent gentlemen painters became the most esteemed artists of the age, especially four masters of the Su-chou area: Shen Chou, Ch'iu Ying, T'ang Yin, and Wen Cheng-ming. Their work, always of great technical excellence, became less and less academic in style; and out of this tradition, by the late years of the dynasty, emerged a conception of the true painter as a professionally competent but deliberately amateurish artist bent on individualistic self-expression. Notably in landscapes, a highly cultivated and somewhat romantic or mystical simplicity became the approved style, perhaps best exemplified in the work of Tung Ch'i-ch'ang.

Ming porcelain

Literature and scholarship. As was the case with much of the painting, Ming poetry and belles lettres were deliberately composed "after the fashion of" earlier masters, and groups of writers and critics earnestly argued about the merits of different T'ang and Sung exemplars. No Ming practitioner of traditional poetry has won special esteem, though Ming literati churned out poetry in prodigious quantities. The historians Sung Lien and Wang Shih-chen and the philosopher-statesman Wang Yang-ming were among the dynasty's most noted prose stylists, producing expository writings of exemplary lucidity and straightforwardness. Perhaps the most admired master was Kuei Yu-kuang, whose most famous writings are simple essays and anecdotes about everyday life—often rather loose and formless but with a quietly pleasing charm, evoking character and mood with artless-seeming delicacy. The iconoclasm of the final Ming decades was mirrored in a literary movement of total individual freedom, championed notably by Yüan Tsung-tao; but writings produced during this period were later denigrated as being insincere, coarse, frivolous, and so strange and eccentric as to make impossible demands on the readers.

The importance of popular fiction

The late Ming iconoclasm did successfully call attention to popular fiction in colloquial style. In retrospect, this must be reckoned the most significant literary work of the late Yüan and Ming periods, despite its being disdained by the educated elite of the time. The late Yüan–early Ming novels *San-kuo chih yen-i* (*Romance of the Three Kingdoms*) and *Shui-hu chuan* (*The Water Margin,* also translated as *All Men Are Brothers*) became the universally acclaimed masterpieces of the historical and picaresque genres, respectively. Sequels to each were produced throughout the Ming period. Wu Ch'eng-en, a 16th-century local official, produced *Hsi-yu chi* (*Journey to the West,* also partially translated as *Monkey*), which became China's most treasured novel of the supernatural; and late in the 16th century an unidentifiable writer produced *Chin P'ing Mei* (also translated as *Golden Lotus*), a realistically Rabelaisian account of life and love among the bourgeoisie, which established yet another genre for the novel. By the end of the Ming period iconoclasts such as Li Chih and Chin Sheng-t'an, both of whom published editions of *Shui-hu chuan,* made the then astonishing assertion that this and other works of popular literature should rank alongside the greatest poetry and literary prose as treasures of China's cultural heritage. Colloquial short stories also proliferated in Ming times, and collecting anthologies of them became a fad of the last Ming century. The master writer and editor in this realm was Feng Meng-lung, whose creations and influence dominate the best-known anthology, *Chin-ku ch'i-kuan* ("Wonders Old and New"), published in Su-chou in 1624.

Operatic drama, which had emerged as a major new art form in Yüan times, was popular throughout the Ming dynasty, and Yüan masterpieces in the tightly disciplined four-act *tsa-chü* style were regularly performed. Ming contributors to the dramatic literature were most creative in a more rambling, multiple-act form known as "southern drama" or as *ch'uan-ch'i.* Members of the Imperial clan and respected scholars and officials such as Wang Shih-chen and particularly T'ang Hsien-tsu wrote for the stage.

A new southern opera aria form called *k'un-ch'ü*, originating in Su-chou, became particularly popular and provided the repertoire of sing-song girls throughout the country. Sentimental romanticism was a notable characteristic of Ming dramas.

Ming scholarship

Perhaps the most representative of all Ming literary activities, however, were voluminous works of sober scholarship in many realms. Ming literati were avid bibliophiles, both collectors and publishers. They founded many great private libraries, such as the famed T'ien-i-ko collection of the Fan family at Ning-po. They also began producing huge anthologies (*ts'ung-shu*) of rare or otherwise interesting books and thus preserved many works from extinction. The example was set in this regard by an Imperially sponsored classified anthology of all the esteemed writings of the whole Chinese heritage completed in 1407 under the title *Yung-lo ta-tien* ("Great Canon of the Yung-lo Era"). Its more than 11,000 volumes being too numerous for even the Imperial government to consider printing, it was preserved only in manuscript copies. Private scholars also produced great illustrated encyclopaedias, including *Pen-ts'ao kang-mu* (late 16th century; "Index of Native Herbs"), a monumental materia medica listing 1,892 herbal concoctions and their applications; *San-ts'ai t'u-hui* (1607–09; "Assembled Pictures of the Three Realms"), a work on subjects such as architecture, tools, costumes, ceremonies, animals, and amusements; *Wu-pei chih* (1621; "Treatise on Military Preparedness"), on weapons, fortifications, defense organization, and war tactics; and *T'ien-kung k'ai-wu* (1637; "Creations of Heaven and Human Labour"), on industrial technology. Ming scholars also produced numerous valuable geographical treatises and historical studies. Among the creative milestones of Ming scholarship, which pointed the way for the development of modern critical scholarship in early Ch'ing times, were the following: a work by Mei Tsu questioning the authenticity of sections of the ancient *Shu Ching* ("Classic of History"); a phonological analysis by Ch'en Ti of the ancient *Shih Ching* ("Classic of Poetry"); and a dictionary by Mei Ying-tso that for the first time classified Chinese characters under 214 radicals and subclassified them by number of brushstrokes—the arrangement of most standard modern dictionaries.

One of the great all-around literati of Ming times, representative in many ways of the dynamic and wide-ranging activities of the Ming scholar-official at his best, was Yang Shen. Yang won first place in the metropolitan examination of 1511, remonstrated vigorously against the caprices of the Cheng-te and Chia-ching emperors, and was finally beaten, imprisoned, removed from his post in the Hanlin Academy, and sent into exile as a common soldier in Yunnan. But he produced poetry and belles lettres in huge quantities, as well as a study of bronze and stone inscriptions through history, a dictionary of obsolete characters, suggestions about the phonology of ancient Chinese, and a classification of fish in Chinese waters. (C.O.Hu.)

The Ch'ing dynasty

EARLY CH'ING

The rise of the Manchu. The Manchu, who ruled China from 1644 to 1911, were descendants of the Juchen tribes who had ruled North China as the Chin dynasty in the 12th century. From the 15th century they had paid tribute to the Ming and been organized in the commandery system, so they had long had extensive and regular contact with the Chinese state and, more importantly, with the Chinese military officers stationed in the Ming frontier garrisons. By the 16th century these officers had become a hereditary regional military group in southern Manchuria, the Manchu homeland. Transformed by their long residence on the frontier, the Chinese soldiers mingled with the "barbarians," adopting Manchu names and tribal customs. Still other Chinese were in the area as enslaved "bond servants" who worked the land or helped manage the trade in ginseng root, precious stones, and furs with China and Korea. Later, after the conquest of China, many of these bond servants became powerful officials who were sent on confidential missions by the emperor and staffed the powerful Imperial Household Department.

Rule of Nurhachi and Abahai

Under Nurhachi and his son Abahai, the Aisin Gioro clan of the Chien-chou tribe won hegemony among the rival Juchen tribes of the northeast, then extended its control through warfare and alliances into Inner Mongolia and Korea. Nurhachi created large permanent civil-military units called "banners" to replace the small hunting groups used in his early campaigns. A banner was composed of smaller companies; it included some 7,500 warriors and their households, including slaves, under the command of a chieftain. Each banner was identified by a coloured flag that was yellow, white, blue, or red, either plain or with a border design. Originally there were four, then eight, Manchu banners; new banners were created as the Manchu conquered new regions, and eventually there were Manchu, Mongol, and Chinese banners, eight for each ethnic group. By 1648 less than 16 percent of the bannermen were actually of Manchu blood. The Manchu conquest was thus achieved with a multiethnic army, led by Manchu nobles and Han Chinese generals. Han Chinese soldiers were organized into the Army of the Green Standard, which became a sort of Imperial constabulary force posted throughout China and on the frontiers.

Modern scholarship on the rise of the Manchu emphasizes the contributions of Chinese collaborators to the Manchu cause. The Manchu offered rewards and high positions to these Chinese, who not only brought military skills and technical knowledge with them but also encouraged the adoption of Chinese institutional models. From Chinese and Korean artisans the Manchu learned iron-smelting technology and acquired the advanced European artillery of the Ming. They created a replica of the Ming central government apparatus in their new capital, Mukden (modern Shen-yang), established in 1625. Whereas Nurhachi had initially based his claim to legitimacy on the tribal model, proclaiming himself khan in 1607, he later adopted the Chinese political language of the T'ien Ming ("Mandate of Heaven") and in 1616 created the Hou (Later) Chin dynasty. Abahai continued to manipulate the political symbols of both worlds by acquiring the great seal of the Mongol khan in 1635, and thus the succession to the Yüan dynasty, and by taking on a Chinese dynastic name, Ch'ing, for his own dynasty the following year.

Factors in the Ming's downfall

The downfall of the Ming house was the product of factors that extended far beyond China's borders. In the 1630s and '40s China's most commercialized regions, the Yangtze Delta and the southeast coast, suffered an acute economic depression brought on by a sharp break in the flow of silver entering ports through foreign trade from Acapulco, Malacca, and Japan. The depression was exacerbated by harvest shortfalls resulting from unusually bad weather during 1626–40. The enervated government administration failed to respond adequately to the crisis, and bandits in the northwest expanded their forces and began invading north and southwest China. One of these bandit leaders, Li Tzu-ch'eng, marched into Peking in 1644 unopposed, and the Emperor, forsaken by his officials and generals, committed suicide. A Ming general, Wu San-kuei, sought Manchu assistance against Li Tzu-ch'eng. Dorgon, the regent and uncle of Abahai's infant son (who became the first Ch'ing emperor), defeated Li and took Peking, where he declared the Manchu dynasty.

It took the Manchu several decades to complete the military conquest of China. In 1673 the conquerors confronted a major rebellion led by three generals (among them Wu San-kuei), former Ming adherents who had been given control over large parts of south and southwest China. This revolt, stimulated by Manchu attempts to cut back on the autonomous power of these generals, was finally suppressed in 1681. In 1683 the Ch'ing finally eliminated the last stronghold of Ming loyalism on Taiwan.

The Ch'ing Empire. After 1683 the Ch'ing rulers turned their attention to consolidating control over their frontiers. Taiwan became part of the empire, and military expeditions against perceived threats in north and west Asia created the largest empire China has ever known. From the late 17th to the early 18th century Ch'ing armies destroyed the Oyrat Empire based in Dzungaria and incorporated into the empire the region around the Koko Nor (Blue

Lake) in Central Asia. In order to check Mongol power, a Chinese garrison and a resident official were posted in Lhasa, the centre of the Dge-lugs-pa (Yellow Hat sect) of Buddhism that was influential among Mongols as well as Tibetans. By the mid-18th century the land on both sides of the Tien Shan range as far west as Lake Balkhash had been annexed and renamed Sinkiang ("New Dominion").

Internal migration

Military expansion was matched by the internal migration of Chinese settlers into parts of China that were dominated by aboriginal or non-Han ethnic groups. The evacuation of the south and southeast coast during the 1660s spurred the westward migration of an ethnic minority, the Hakka, who moved from the hills of southwest Fukien, northern Kwangtung, and southern Kiangsi. Although the Ch'ing dynasty tried to forbid migration into its homeland, Manchuria, in the 18th and 19th centuries Chinese settlers flowed into the fertile Liao River basin. Government policies encouraged Han movement into the southwest during the early 18th century, while Chinese traders and assimilated Chinese Muslims moved into Sinkiang and the other newly acquired territories. This period was punctuated by ethnic conflict stimulated by the Han Chinese takeover of former aboriginal territories and by fighting between different groups of Han Chinese.

Political institutions. The Ch'ing had come to power because of their success at winning Chinese over to their side; in the late 17th century they adroitly pursued similar policies to win the adherence of the Chinese literati. Ch'ing emperors learned Chinese, addressed their subjects using Confucian rhetoric, reinstated the civil service examination system and the Confucian curriculum, and patronized scholarly projects, as had their predecessors. They also continued the Ming custom of adopting reign names, so that Hsüan-yeh, for example, is known to history as the K'ang-hsi emperor. The Ch'ing rulers initially used only Manchu and bannermen to fill the most important positions in the provincial and central governments (half of the powerful governors-general throughout the dynasty were Manchu), but Chinese were able to enter government in greater numbers in the 18th century, and a Manchu-Han dyarchy was in place for the rest of the dynasty.

The early Ch'ing emperors were vigorous and forceful rulers. The first emperor, Fu-lin (reign name, Shun-chih), was put on the throne when a child of six *sui* (about five years in Western calculations). His reign (1644–61) was dominated by his uncle and regent, Dorgon, until Dorgon died in 1650. Because the Shun-chih emperor had died of smallpox, his successor, the K'ang-hsi emperor, was chosen in part because he had already survived a smallpox attack. The K'ang-hsi emperor (reigned 1661–1722) was one of the most dynamic rulers China has known. During his reign the last phase of the military conquest was completed, and campaigns were pressed against the Mongols to strengthen Ch'ing security on its Inner Asian borders. China's literati were brought into scholarly projects, notably the compilation of the Ming history, under Imperial patronage.

The K'ang-hsi emperor's designated heir, his son Yin-jeng, was a bitter disappointment, and the succession struggle that followed the latter's demotion was perhaps the bloodiest in Ch'ing history. Many Chinese historians still question whether the K'ang-hsi emperor's eventual successor, his son Yin-chen (reign title, Yung-cheng), was truly the emperor's deathbed choice. During the Yung-cheng reign (1722–35) the government promoted Chinese settlement of the southwest and tried to integrate non-Han aboriginal groups into Chinese culture; it reformed the fiscal administration and rectified bureaucratic corruption.

Ch'ien-lung reign

The Ch'ien-lung reign (1735–96) marked the culmination of the early Ch'ing. The Emperor had inherited an improved bureaucracy and full treasury from his father and expended enormous sums on the military expeditions known as the Ten Great Victories. He was both noted for his patronage of the arts and notorious for the censorship of anti-Manchu literary works that was linked with the compilation of the *Ssu-k'u ch'üan-shu* ("Complete Library of the Four Treasuries"; Eng. trans. under various titles). The closing years of his reign were marred by intensified court factionalism centred on the meteoric rise to political power of an Imperial favourite, a young officer named Ho-shen. Yung-yen, who reigned as the Chia-ch'ing emperor (1796–1820), lived most of his life in his father's shadow. He was plagued by treasury deficits, piracy off the southeast coast, and uprisings among aboriginal groups in the southwest and elsewhere. These problems, together with new pressures resulting from an expansion in opium imports, were passed on to his successor, the Tao-kuang emperor (reigned 1820–50).

The early Ch'ing emperors succeeded in breaking from the Manchu tradition of collegial rule. The consolidation of Imperial power was finally completed in the 1730s, when the Yung-cheng emperor destroyed the power base of rival princes. By the early 18th century the Manchu had adopted the Chinese practice of father–son succession but without the custom of favouring the eldest son. Because the identity of the Imperial heir was kept secret until the emperor was on his deathbed, Ch'ing succession struggles were particularly bitter and sometimes bloody.

The Manchu also altered political institutions in the central government. They created an Imperial Household Department to forestall the usurpation of power by eunuchs that had plagued the Ming ruling house, and they staffed this agency with bond servants. The Imperial Household Department became a power outside the control of the regular bureaucracy. It managed the large estates that had been allocated to bannermen and supervised various government monopolies, the Imperial textile and porcelain factories in central China, and the customs bureaus scattered throughout the empire. The size and strength of the Imperial Household Department reflected the accretion of power to the throne that was part of the Ch'ing political process. Similarly, revisions of the system of bureaucratic communication and the creation in 1729 of a new top decision-making body, the Grand Council, permitted the emperor to control more efficiently the ocean of government memorandums and requests.

Imperial Household Department

Foreign relations. The Manchu inherited the tributary system of foreign relations from previous dynasties. This system assumed that China was culturally and materially superior to all other nations, and it required those who wished to trade and deal with China to come as vassals to the emperor, who was the ruler of "all under Heaven." The tributary system was used by the Ch'ing Board of Rites to deal with the countries along China's eastern and southern borders and with the European nations that sought trade at the ports of south and southeast China.

The tributary system operated in its fullest form in the Ch'ing treatment of Korea. The Korean court used the Chinese calendar, sent regular embassies to Peking to present tribute, and consulted the Chinese on the conduct of foreign relations. The Ch'ing emperor confirmed the authority of the Korean rulers, approved the Korean choice of consorts and heirs, and bestowed noble ranks on Korean kings. The Korean envoy performed the kowtow (complete prostration and knocking of the head on the ground) before the Ch'ing emperor and addressed him using the terms appropriate to someone of inferior status.

Central Asia was another matter. Tribes on the Inner Asian frontiers had repeatedly invaded China, and the Manchu, who had been part of the world of the steppe, were keenly aware of the need for military supremacy on China's northern borders. Inner Asian affairs were handled by a new agency, the Court of Colonial Affairs, that was created before 1644. Ch'ing policies toward Central Asia frequently deviated from the tributary ideal. Chinese relations with Russia are a case in point. The early Ch'ing rulers attempted to check the Russian advance in north Asia and used the Russians as a buffer against the Mongols. The Sino-Russian Treaty of Nerchinsk (1689), which tried to fix a common border, was an agreement between equals. The Treaty of Kyakhta (1727) extended agreement on the borders to the west and opened markets for trade. When Chinese ambassadors went to Moscow (1731) and St. Petersburg (1732) to request that Russia remain neutral during the Chinese campaigns against the Oyrat in Central Asia, they performed the kowtow before the Empress.

Foreign trade was not always restricted to the formal exchanges prescribed by the tributary system. Extensive trad-

ing was carried out in markets along China's borders with Korea, at the Russo-Mongolian border town of Kyakhta, and at selected ports along the coast, whence ships traded with Southeast Asia. Perhaps the most striking example of trade taking precedence over tribute was the Ch'ing trade with Japan. The Tokugawa shogunate viewed the Ch'ing as barbarians whose conquest sullied China's claim to moral superiority in the world order. They refused to take part in the tributary system and themselves issued trade permits (counterparts of the Chinese tributary tallies) to Chinese merchants coming to Nagasaki after 1715. The Ch'ing need for Japanese copper, a money metal in China, required that trade with Japan be continued, and it was.

Relations with Japan

Economic development. In the 1640s and '50s the Manchu abolished all late Ming surtaxes and granted tax exemptions to areas ravaged by war. Tax remissions were limited, however, by the urgent need for revenues to carry on the conquest of China. It was not until the 1680s, after the consolidation of military victory, that the Ch'ing began to permit tax remissions on a large scale. The permanent freezing of the *ting* (corvée quotas) in 1712 and the subsequent merger of the *ting* and land tax into a single tax that was collected in silver were part of a long-term simplification of the tax system. The commutation of levies from payment in kind to payment in money and the shift from registering males to registering land paralleled the increasing commercialization of the economy.

A healthy tax base required that land be brought under cultivation. Because more than one-quarter of the total cultivated land had slipped off the tax rolls in the early 17th century, the restoration of agriculture was an important goal. The new dynasty began to resettle refugees on abandoned land with offers of tax exemptions for several years and grants of oxen, tools, seeds, or even cash in some areas. In the late 17th century the resettlement of the Ch'eng-tu Basin in western China and of Hunan, Hupeh, and the far southwest proceeded on this basis.

Land reclamation went hand in hand with the construction and reconstruction of water-control projects. This was an activity so characteristic of a new dynasty that one can speak of "hydraulic cycles" moving in tandem with political consolidations in China. These water-control projects varied in scale with terrain and ecology. In central and South China irrigation systems were the foundation for rice cultivation and were largely the product of private investment and management. In North China control of the heavily silted Huang Ho (Yellow River), which frequently inundated the eastern portion of the North China Plain, required large-scale state management and coordination with the related water level of the Grand Canal, the major north–south waterway supplying Peking.

The preferred crops—rice in central and South China, wheat in North China—retained their primacy in Ch'ing agriculture. In the course of the dynasty, the cultivation of wheat and other northern staple grains continued to creep southward; rice was transplanted to the best lands on the frontiers, and there was a gradual intensification of the cropping cycle. Both on the frontiers and within China proper new lands were opened for settlement using the New World crops that had been introduced into China in the late 16th century. Corn (maize) and the Irish potato permitted Chinese to cultivate the marginal hilly lands. The sweet potato provided insurance against famine, while peanuts (groundnuts) were a new source of oil in the peasant diet. Tobacco, another 16th-century import, competed with rice and sugarcane for the best lands in South China and became an important cash crop.

Once the economy had been restored, the Ch'ing state attempted to keep it running smoothly. For the most part, the state did not actively intervene in what was becoming an extremely complex market economy. The major exception was its successful effort to offset regional food shortages in years of crop failure. Every province was supposed to purchase or retain reserves in the "ever-normal" granaries located in each county, so named because they were intended to stabilize the supply, and hence the price, of grain. Even relatively uncommercialized hinterlands were thus armoured against famine. The ability of the government to respond effectively to food scarcity was dependent on its information gathering. During the 18th century data on local grain prices became a regular feature of county, prefectural, and provincial reports.

The Ch'ing government played a relatively minor role in the commercial economy. There were state monopolies in salt, precious metals, pearls, and ginseng, but the long-run trend was to reduce the number of monopolies. The state barely began to tap the growing revenue potential of trade, just as it failed to tap the expanding agricultural base. Its rare interventions in trade were motivated by a desire to dampen economic fluctuations in employment. Its major goal was stability, not growth.

Economic growth

And yet the early Ch'ing was a period of economic growth and development. With the imposition of the Ch'ing peace, the economy resumed a commercial expansion that had begun in the 16th century. This expansion in turn stimulated specialization in crops sent to market, which included raw materials to be used in the textile industry as well as consumption goods such as tea, sugar, and tobacco. Profit enticed merchants, landlords, and peasants to buy or rent land to produce cash crops. A new kind of managerial landlord, who used hired labour to grow market crops, emerged in the 18th century.

The tenant's position improved vis-à-vis the landlord's, a wage-labour force arose in agriculture, and land was increasingly used as a marketable commodity. Systems that guaranteed tenants permanent rights of cultivation spread in the 18th century through the wet-rice cultivation zone and in some dryland cultivation systems. Multiple layers of rights to the land generally benefited the tenant and improved incentives to maintain the fertility of the soil and to raise output. There was a general shift from servile to contractual labour in agriculture that was part of a long trend toward the elimination of fixed status and the increased mobility of labour and land.

Equally important processes of commercialization gained momentum with the recovery of the domestic economy. The 16th-century boom created new layers of rural markets that linked villages more firmly to a market network. Although the majority of economic transactions continued to take place within local and intermediate markets, there was a significant expansion of interregional and national trade in grain, tea, cotton, and silk. In the 18th century Shanghai became a thriving entrepôt for the coastal trade that extended from Manchuria to South China.

Emergence of a banking system

The most dramatic economic innovations of the 18th century resulted from the needs of long-distance traders for credit and new mechanisms that would ease the transfer of funds. Native banks, as they were called by foreigners in the 19th century, accepted deposits, made loans, issued private notes, and transferred funds from one region to another. Promissory notes issued by native banks on behalf of merchants facilitated the purchase of large quantities of goods, and money drafts and transfer accounts also helped ease the flow of funds. By the early 19th century, paper notes may have constituted one-third or more of the total volume of money in circulation. The demands of large-scale, long-distance trade had, without government participation, inspired merchants to transform a metallic monetary system into one in which paper notes supplemented copper coins and silver.

Customary law evolved outside the formal legal system to expedite economic transactions and enable strangers to do business with one another. Business partnerships in mining, commerce, and commercial agriculture could be formalized and protected through written contract. Reliance on written contracts for the purchase and mortgaging of land, purchase of commodities and people, and hiring of wage labourers became commonplace.

The early Ch'ing economy was intimately tied to foreign trade, which consisted of a junk trade with ports in Southeast Asia, Japan, and the Philippines and the expanding trade conducted by Europeans. After 1684, when the ban on maritime trade was lifted, Western traders flocked to Canton, and foreign commerce was finally confined to this port in 1759. The "Canton system" of trade that prevailed from that year until 1842 specified that Europeans had to trade through the cohong, a guild of Chinese firms that had monopoly rights to the trade in tea and silk.

From 1719 to 1833 the tonnage of foreign ships trading at Canton increased more than 13-fold. The major export was tea; by 1833 tea exports were more than 28 times the export levels of 1719. Silk and porcelain were also exported in increasing quantities through the early 18th century. Although exports remained a small fraction of total output, the effect of foreign trade on the Chinese economy was direct and perceptible. Its repercussions were not limited to the merchants and producers involved in specific export commodities but also had a general impact on domestic markets through the monetary system.

The Chinese economy had long been based on a metallic currency system in which copper cash was used for daily purchases and silver for large business transactions and taxes. The exchange ratio between silver and copper cash was responsive to fluctuations in the supply of the metals, and changes in the exchange ratio affected all citizens. The economic expansion of the 18th century brought rising demand for silver and copper. Although domestic production of copper increased, silver was primarily obtained from abroad. After 1684 the net balance of trade was consistently in China's favour, and silver flowed into the Chinese economy. Perhaps 10,000,000 Spanish silver dollars a year came into China during the early Ch'ing, and in the 18th century Spanish silver dollars became a common unit of account in the southeast and south.

Ch'ing society. Chinese society continued to be highly stratified during the early Ch'ing. Hereditary status groups in the society ranged from the descendants of the Imperial line down to the "mean people" at the bottom of the social ladder. Many professions were hereditary: bannermen, brewers, dyers, doctors, navigators, and Taoist priests usually passed on their occupations to at least one son in each generation. The "mean people" included remnants of aboriginal groups who had survived Chinese expansion and settlement and certain occupational groups, including prostitutes, musicians, actors, and local government underlings (jailers and gatekeepers, for example). Ch'ing laws forbade intermarriage between respectable commoners ("good people") and the mean people, who were also barred from sitting for the civil service examinations. Despite attempts in the 1720s to return some of these mean people to ordinary commoner status, the social stigma persisted throughout the dynasty.

Servitude was commonplace in Ch'ing society. The Manchu had enslaved prisoners of war, and in China persons could be sold by their families. Many well-to-do households owned some domestic servants. Grouped with the mean people in Ch'ing law, some servants nonetheless achieved considerable power and authority. Bond servants of the Imperial house ran the powerful Imperial Household Department and themselves owned slaves. Servile tenants of the wealthy Hui-chou merchants were sometimes raised as companions to the master's son and trusted to help run the long-distance trade on which Hui-chou fortunes were based. Servitude in some cases was thus an important avenue for social advancement.

Social mobility

Social mobility increased during the early Ch'ing, supported by a pervasive belief that it was possible for a peasant boy to become the first scholar in the land. An ethic that stressed education and hard work motivated many households to invest their surplus in the arduous preparation of sons for the civil service examinations. Although the most prestigious career in Ch'ing society remained that of the scholar-official, the sharpened competition for degrees in the prosperous 18th century brought a significant expansion in socially acceptable forms of achievement. At one pole, alienated literati deliberately eschewed the morally ambiguous role of official to devote their energies to scholarship, painting, poetry, and the other arts. Others turned to management of their localities and assumed leadership in public welfare, mediation of disputes, and local defense. Families with a long tradition of success in examinations and official service were increasingly preoccupied with strategies for ensuring the perpetuation of their elite status and countering the inexorable division of family estates stemming from the Chinese practice of partible inheritance. Downward mobility was a more general phenomenon than upward mobility in Ch'ing society: those at the bottom of the social scale did not marry and reproduce themselves, while the wealthy practiced polygyny and tended to have many children.

In China's long-settled and densely populated regions, degree holders who confronted the prospect of downward mobility for their sons were profoundly disturbed about the circumstances that permitted rich merchants to mimic their way of life. The money economy and its impersonal values penetrated more deeply into Chinese society than ever before, challenging former indicators of status for preeminence. Alarmed, the Chinese elite joined the Ch'ing state in trying to propagate traditional values and behaviour. Morality books, published in increasing quantities from the late 16th century onward, tied virtuous behaviour to concrete rewards in the form of educational success, high office, and sons. The Ch'ing bestowed titles, gifts, and Imperial calligraphy on virtuous widows and encouraged the construction of memorial arches and shrines in their honour to reinforce this female role. Rural lectures (*hsiang-yüeh*) were public ceremonies staged for citizens that combined religious elements with the recitation of the Sacred Edict promulgated by the emperor.

Social organization. The basic unit of production and consumption in Chinese society remained the *chia* ("family"), consisting of kin related by blood, marriage, or adoption, with a common budget and common property. The Chinese family system was patrilineal; daughters married out, while sons brought in wives and shared the residence of their fathers. The head of the family, the patriarch, had the power to direct the activities of each member in an effort to optimize the family's welfare. The family was a metaphor for the state, and family relations were the foundation of the hierarchical social roles that were essential in the Confucian vision of a morally correct society.

In southeast and South China the early Ch'ing saw an expansion of extended kinship organizations based on descent from a common ancestor. In these areas lineages became a powerful tool for collective action and local dominance, using revenues from corporate property to support education, charity, and ancestral rites. Other types of lineages, possessing little corporate property, existed in other parts of China. These lineages seem to have been composed of only the most elite lines within a descent group, who focused their efforts on national rather than local prominence and emphasized their marriage networks rather than ties to poorer kinsmen.

Kinship was of limited use to the increasingly numerous sojourners who were working away from home in the early Ch'ing. Other kinds of organizations emerged to meet the needs of a more mobile population. The share partnership permitted unrelated persons to pool their resources to start a business, and it was used to finance a wide variety of enterprises, including mining ventures, coastal and overseas shipping, commercial agriculture, money shops, and theatres. The trading empires created by the Hui-chou and Shansi merchants were examples of how such partnerships, cemented by kinship and native-place ties, could be used for large-scale business operations.

The *hui-kuan* and *kung-so* organizations

"Native place" was the principle used to organize the *hui-kuan* (native-place associations) that spread throughout Ch'ing market centres. Some *hui-kuan* were primarily intended for officials and examination candidates; these were located in the capitals of provinces and in Peking. Others, located in the southwest, were for immigrants, but the vast majority were created and used by merchants. The *hui-kuan* provided lodging and a place to meet fellow natives, receive financial aid, and store goods. In the course of the 18th century another kind of organization that encompassed all the men in a trade, the *kung-so* (guild), emerged in China's cities. *Hui-kuan* frequently became subunits of *kung-so,* and both groups participated in the informal governance of cities.

New kinds of social organization also emerged on China's frontiers. Native-place ties were frequently expressed in worship of a deity, so that a temple or territorial cult would become a vehicle for collective action. White Lotus sectarianism appealed to other Chinese, most notably to women and to the poor, who found solace in worship of the Eternal Mother who was to gather all her children at

the millennium into one family. The Ch'ing state banned the religion, and it was generally an underground movement. Although the White Lotus faith was practiced by boatmen on the Grand Canal with no attempts to foment uprising, its millenarian message spurred spectacular rebellions, the most notable being the White Lotus Rebellion at the close of the 18th century.

A new form of social organization, based on sworn brotherhood, emerged among male sojourners in southeast China in the late 18th century. The Triad fraternities built on kinship, native-place, and contractor–worker ties but added special rituals that bound fellow workers together as "brothers" in discipleship to a monk founder. Secret lore, initiation rituals, and an elaborate origin myth evolved, but the fraternities tended to be highly decentralized autonomous units. Appearing first on Taiwan, the Triads expanded with transport workers into South China and became a powerful organization that dominated the Chinese underworld.

State and society. The state barred literati from using the academies and literary societies for explicitly political activities. Scholars in Peking and in the rich cities of the Yangtze Delta turned from politics to the study of texts that marked the empirical school of scholarship (*k'ao-cheng hsüeh*). Influenced by their knowledge of European mathematics and mathematical astronomy, these scholars laid down new rules for verifying the authenticity of the Classical texts and, by revealing flaws in previously accepted canons, challenged the Neo-Confucian orthodoxy. Turning away from the Confucian quest for sagehood, the empirical scholars were increasingly secular and professional in their pursuit of textual studies. Scholarly associations, poetry societies, and academies were the organizational loci for the empirical schools. Great libraries were created, rare texts were reprinted, and compilation projects proliferated, culminating in the great government-sponsored *Ssu-k'u ch'üan-shu* (1772–82), which undertook to collect for reprinting the best editions of the most important books produced in China, using as selection criteria the methods of the empirical school.

Spread of urban culture

Ch'ing society saw the expansion and extension of a national urban culture into various parts of the empire. Urban culture circulated through the market network into the hinterland, as sojourners disseminated culture from localities into the cities and back again. The dissemination of this culture was also supported by increased functional literacy and the expansion of large-scale printing for commercial and scholarly audiences. There was a wide variety of written materials available in market towns and cities—collections of winning examination essays, route books for commercial travelers, religious pamphlets and scriptures, novels, short story collections, jokebooks, and almanacs. Storytelling, puppet plays, and regional drama in rural and urban places provided yet another mode of cultural dissemination. In China's cities sojourning merchants sponsored visits of drama troupes from their own localities; in this way, regional drama also spread outside its own territory. Drama was the bridge connecting the oral and written realms, the "living classroom" for peasants who learned about cultural heroes and history through watching plays. The expansion of a national urban culture supported the state's efforts to systematize and standardize Chinese society.

China's non-Han minorities found themselves surrounded by an aggressive, expansionist Han Chinese culture during the early Ch'ing. Early attempts by the emperors to protect minorities from the Han onslaught were largely unavailing, and some rulers such as the Yung-cheng emperor actually tried to hasten the assimilation of aboriginal groups into the Chinese order. The Ch'ing categorized these ethnic minorities into two groups: those who were "raw," or still possessed of their own culture, and those who were "cooked," or assimilated. Despite violent resistance, the ethnic minorities were gradually assimilated or pushed further south and west during the early Ch'ing.

Trends in the early Ch'ing. The tripling of China's population from the beginning of the Ch'ing dynasty to the mid-19th century rested on the economic expansion that followed the consolidation of Manchu rule. This population growth has been frequently cited as the major cause of the decline of China in the 19th century. Certainly the year 1800 saw the Ch'ing state's surpluses, sufficient through the 18th century to pay for numerous military expeditions, exhausted in the long campaign to quell the White Lotus Rebellion. Whereas fiscal reforms had strengthened the state in the 18th century, fiscal weakness plagued Ch'ing governments in the 19th. The vaunted power of the Ch'ing armies also waned after 1800, in part because of new modes of warfare. Increased commercialization had tied more and more Chinese into large market fluctuations. In the 18th century the world market economy into which China was increasingly integrated worked in its favour and stimulated a long period of internal prosperity. But the favourable trend was reversed in the 1820s and '30s, when rising importation of opium altered the net balance of trade against China and ushered in a period of economic depression. (E.S.R.)

LATE CH'ING

Western challenge, 1839–60. The opium question, the direct cause of the first Sino-British clash in the 19th century, began with a late 18th-century British attempt to counterbalance their unfavourable China trade with traffic in Indian opium. After monopolizing the opium trade in 1779, the East India Company's government began to sell the drug at auction to private British traders in India, who shipped it to buyers in China. The silver acquired from the sale of opium in China was sold at Canton for the company's bills of exchange, payable in London, and was used by the company to purchase its large annual tea cargo for sale in Europe. This "triangular trade" became a major vehicle for realizing the potential gains from the British conquest of India, providing as it did a means to repatriate the company's Indian revenue in opium in the form of Chinese teas. In 1819 the company began to handle larger amounts of opium. Substantial social and economic disruption resulted from the spread of the opium habit and of corruption among petty officials and from a fall in the value of copper in China's bimetallic monetary system as silver was drained from the economy. The Peking court repeatedly banned the importing of opium but without success, because the prohibition itself promoted corruption among the officials and soldiers concerned. There was no possibility of the opium question being solved as a domestic affair.

Trade in tea and opium

After the turn of the 19th century the main vehicle of opium smuggling was the country traders who were allowed only to manage the inter-Asian trade under the company's license. Without protection from the company, they cultivated the opium market in China on their own. They defied the opium ban in China and gradually became defiant toward Chinese law and order in general, having nothing in mind but making money. After Parliament revoked the East India Company's monopoly in 1834, William John Napier was appointed chief superintendent of British trade in China and arrived at Canton. He tried to negotiate with the Canton authorities on equal footing, but the latter took his behaviour as contrary to the established Sino-foreign intercourse. His mission failed.

In Peking an 1836 proposal to relax the opium restraint acquired much support. But the Tao-kuang emperor appointed a radical patriot, Lin Tse-hsü, as Imperial commissioner for an anti-opium campaign. Chinese anti-opium efforts, in fact, began to make considerable headway in controlling the Chinese side of the smuggling trade in late 1838 and early 1839. The critical foreign side of the opium trade was, however, beyond Commissioner Lin's direct reach. Arriving at Canton in March 1839, Lin confiscated and destroyed more than 20,000 chests of opium. Skirmishes began after September between the Chinese and the British.

The first Opium War and its aftermath. In February 1840 the British government decided on an expedition, and Rear Adm. George Elliot was appointed first commissioner and plenipotentiary to China. In June, 16 British warships arrived in Hong Kong and sailed northward to the mouth of the Pei River to press China with its demands. No agreement was reached. In May 1841 the

British attacked the walled city of Canton and received a ransom of $6,000,000, which provoked a counterattack on the part of the Cantonese. This was the beginning of a continuing conflict between the British and the Cantonese.

The Ch'ing had no effective tactics against the powerful British Navy. They retaliated merely by setting burning rafts on the enemy's fleet; and they encouraged people to take the heads of the enemies, for which they offered a prize. The Imperial banner troops, although they sometimes fought fiercely, were ill-equipped and lacked training for warfare against the more modern British forces. The Green Standard battalions were similarly in decay and without much motivation or good leadership. To make up the weakness, local militias were urgently recruited, but they were useless. The British proclaimed that their aim was to fight the government officials and soldiers who abused the people, not to make war against the Chinese population. And indeed there was a deep rift between the government and people, of which the British could easily take advantage, a weakness in Ch'ing society that became apparent in the crisis of the war.

Elliot's successor, Henry Pottinger, arrived at Macau in August and campaigned northward, seizing Amoy, Tinghai, and Ning-po. Reinforced from India, he resumed action in May 1842 and took Wu-sung, Shanghai, and Chen-chiang. Nanking yielded in August, and peace was restored with the Treaty of Nanking. The main provisions of the treaty were the cession of Hong Kong, the opening of five ports to British trade, the abolition of the cohong system of trade, equality of official recognition, and an indemnity of $21,000,000. This was the result of the first clash between China, which had regarded foreign trade as a favour given by the Heavenly empire to the poor barbarians, and the British, to whom trade and commerce had become "the true herald of civilization."

The Treaty of Nanking

The Treaty of Nanking was followed by two supplementary arrangements with the British in 1843. In July 1844 China signed the Treaty of Wanghia with the United States and in October the Treaty of Whampoa with France. These arrangements made up a complex of foreign privileges by virtue of the most-favoured-nation clauses (guaranteeing trading equality) conceded to every signatory. All in all, they provided a basis for such later evils as the loss of tariff autonomy, extraterritoriality (exemption from the application or jurisdiction of local law or tribunals), and the free movement of missionaries.

With the signing of the treaties—which began the so-called treaty-port system—the Imperial commissioner Ch'i-ying, newly stationed at Canton, was put in charge of foreign affairs. Following a policy of appeasement, his dealing with foreigners started fairly smoothly. But contrary to the British expectation, the amount of trade dropped after 1846; and, to their dissatisfaction, the question of opium remained unsettled in the postwar arrangements. The core of the Sino-Western tension, however, rested in an antiforeign movement in Kwangtung.

Antiforeign movement and the Arrow, or second Opium, War. At the signing of the Treaty of Nanking there was a difference between China and Britain as to whether foreigners were allowed to enter the walled city of Canton. Though Canton was declared open in July 1843, the British faced Cantonese opposition. After 1847 trouble rapidly grew, and as a result of an incident at nearby Fo-shan, a promise was given the British that they would be allowed to enter the city in 1849. Yet troubles continued. As a result of his inability to control the situation, Ch'i-ying was recalled in 1848 and replaced with the less compliant Hsü Kuang-chin. As the promised date neared, the Cantonese demonstrated against British entry. Finally, the British yielded, and the antiforeigners won a victory despite the fact that the Peking court conceded a "temporary entrance" into the city.

After the Cantonese resistance in 1841, the gentry in Kwangtung began to build a more organized antiforeign movement, promoting the militarization of village society. The city of Canton was also a centre of diffusion of xenophobia because the scholars at the city's great academies were proclaiming the Confucian theory that uncultured barbarians should be excluded. The inspired antiforeign mood also contained a strong antigovernment sentiment and perhaps a tendency toward provincialism; the Cantonese rose up against the barbarians to protect their own homeland, without recourse to the government authorities.

In the strained atmosphere in Canton, where the xenophobic governor-general, Yeh Ming-ch'en, was inciting the Cantonese to annihilate the British, the *Arrow* incident occurred in October 1856. Canton police seized the *Arrow*, a Chinese-owned but British-registered ship flying a British flag, and charged its Chinese crew with piracy and smuggling. The British consul Harry Parkes sent a fleet to fight its way up to Canton. French forces joined the venture on the plea that a missionary had been officially executed in Kwangsi. The British government sent an expedition under Lord Elgin as a plenipotentiary. The Russians and the Americans abstained but sent their representatives for diplomatic maneuvering. At the end of 1857 an Anglo-French force occupied Canton; in March 1858 they took the Ta-ku fort and marched to Tientsin.

Foreign gains

The Ch'ing representatives had no choice but to comply with the demands of the British and French; the Russian and U.S. diplomats also gained the privileges their militant colleagues secured by force. During June four Tientsin treaties were concluded that provided for, among other measures, the residence of foreign diplomats in Peking and the freedom of Christian missionaries to evangelize their faith.

In 1859 when the signatories arrived off the Ta-ku fort on their way to sign the treaties in Peking, they were repulsed, with heavy damage inflicted by the gunfire from the fort. In 1860 an allied force invaded Peking, driving the Hsien-feng emperor (reigned 1850–61) out of the capital to the summer palace at Cheng-te. A younger brother of the emperor, Prince Kung Ch'in-wang, was appointed Imperial commissioner in charge of negotiation. But the famous summer palace was destroyed by the British in October. Following the advice of the Russian negotiator, Prince Kung exchanged ratification of the 1858 treaties; in addition, he signed new conventions with the British and the French. The U.S. and Russian negotiators had already exchanged the ratification in 1859, but the latter's diplomatic performance in 1860 was remarkable.

Russian interests in the East had been activated in competition with the British effort to open China. A Russian spearhead, directed to Kuldja (modern I-ning) by way of the Irtysh River, resulted in the Sino-Russian Treaty of Kuldja in 1851, which opened Kuldja and Chuguchak (modern T'a-ch'eng) to Russian trade. Another drive was directed to the Amur watershed under the initiative of Nikolay Muravyov, who had been appointed governor-general of eastern Siberia in 1847. By 1857 Muravyov had sponsored four expeditions down the Amur; in the third one, in 1856, the left bank and lower reaches of the river had actually been occupied by the Russians. In May 1858 Muravyov pressed the Ch'ing general I-shan to sign a treaty at Aigun (modern Ai-hui), by which the territory on the northern bank of the Amur was ceded to Russia and the land between the Ussuri River and the sea was placed in joint possession by the two nations, pending further disposition. But Peking refused to ratify the treaty. When the Anglo-French allies attacked North China in 1860, the Russian negotiator Nikolay Ignatyev acted as China's friend and mediator in securing the evacuation of the invaders from Peking. Soon after the allies had left Peking, Ignatyev secured, as a reward for his mediatory effort, the Sino-Russian Treaty of Peking, which confirmed the Treaty of Aigun and ceded to Russia the territory between the Ussuri and the sea.

Effects of the treaties of 1858–60

The 1858–60 treaties extended the foreign privileges granted after the first Opium War and confirmed or legalized the developments in the treaty-port system. The worst effects for the Ch'ing authorities were not the utilitarian rights, such as trade, commerce, and tariff, but the privileges that affected the moral and cultural values of China. The right to propagate Christianity threatened Confucian values, the backbone of the Imperial system. The permanent residence of foreign representatives in Peking signified an end to the long-established tributary relationship between China and other nations. The partial collapse of

the tribute system meant a loss of the emperor's virtue, a serious blow to dynastic rule in China.

During the turbulent years 1858–60, the Ch'ing bureaucracy was divided between the war and peace parties; and it was the peace party's leaders—Prince Kung, Kuei-liang, and Wen-hsiang—who took charge of negotiating with the foreigners. But they did so because the imminent crisis forced them to and not as a matter of principle.

In 1861 in response to the settlement of the foreign representatives in the capital, the Tsungli Yamen (office for General Management) was opened to deal with foreign affairs, with a main staff filled by the peace-party leaders. The Ch'ing officials themselves, however, deemed this as still keeping a faint silhouette of the tribute system.

The delay and difficulty in the Ch'ing adjustment to the West may possibly be ascribed to both external and internal factors. The Chinese must have seen the Westerners who had appeared in China as purveyors of poisonous drugs, as barbarians in the full sense of the word, from whom they could learn nothing. But the Chinese staunchly held to their tradition, which also had two aspects—ideological and institutional. The core of the ideological aspect was the Confucian distinction between China and foreign nations. The institutional aspect had recently been much studied, however, and precedents in Chinese history had been found, for example, of treaty ports with foreign settlements, consular jurisdiction, and employment of Westerners as Imperial personnel; thus, the Chinese regarded the Western impact as an extension of their tradition rather than as a totally new situation that necessitated a new adjustment. And at least until 1860 the Ch'ing leaders remained withdrawn in the shell of tradition, making no effort to cope with the new environment by breaking the yoke of the past.

Popular uprising. The third quarter of the 19th century saw a series of uprisings, again as a result of social discontent.

The Taiping Rebellion. In the first half of the 19th century the province of Kwangtung, the homeland of the Taiping people, was beset with accelerating social unrest. After the first Opium War, government prestige declined, and officials lost their capacity to reconcile communal feudings. The greatest among such conflicts was that between the native settlers and the so-called guest settlers—the Hakka, who had migrated to Kwangsi and western Kwangtung, mainly from eastern Kwangtung. The Pai Shang-ti Hui (God Worshipers' Society) was founded by Hung Hsiu-ch'üan, a fanatic who believed himself a son of God, and his protégé, Feng Yün-shan, an able organizer. Their followers were collected from among miners, charcoal workers, and poor peasants in central Kwangsi, most of whom belonged to the Hakka. In January 1851 a new state named T'ai-p'ing T'ien-kuo (Heavenly Kingdom of Great Peace) was declared in the district of Kuei-p'ing in Kwangsi with Hung Hsiu-ch'üan proclaimed Heavenly king. That September the Taiping shifted their base to the city of Yung-an, where they were besieged by the Imperial army until April 1852. Then they broke the siege and rushed into Hunan. Absorbing some secret-society members and outlaws, they dashed to Wu-han, the capital of Hupeh, and proceeded along the Yangtze to Nanking, which they captured in March 1853 and made their capital.

Taiping religion

The core of the Taiping religion was a monotheism tinged with fundamental Protestant Christianity. But it was mixed with a hatred of the Manchu and an intolerance of the Chinese cultural tradition. In the early years of the rebellion this politico-religious faith sustained the fighting spirit of the Taiping. In the ideal Taiping vision the population was to give all of its belongings to a "general treasury," which would be shared by all alike. While this extreme egalitarianism was rarely implemented outside the original Hakka core from Kwangsi, it probably at times attracted the distressed and lured them to the Taiping cause. The origin of many Taiping religious ideas, morals, and institutions can be traced to China's Confucian tradition; but the Taiping's all-out antiregime struggle, motivated by strong religious beliefs and a common sharing, also had precedents in earlier religious rebellions.

After the Taiping settled in Nanking, village officials were appointed, and redistribution of farmland was planned in accordance with an idea of primitive communism. But in fact the land reform was impracticable. The village officials' posts were filled mainly by the former landlords or the clerks of the local governments, and the old order in the countryside was not replaced by a new one that the oppressed people could dominate.

In May 1853 the Taiping sent an expedition to northern China, which reached the neighbourhood of Tientsin but finally collapsed during the spring of 1855. After this, the Yangtze Valley provinces were the main theatre of struggle. Of the government armies in those years, the Green Standards were too ill disciplined, and not much could be expected of the bannermen. The Ch'ing government had no choice but to rely on the local militia forces, such as the "Hunan Braves" (later called the Hunan Army), organized by Tseng Kuo-fan in 1852, and the "Huai Braves" (later called the Huai Army), organized by Li Hung-chang in 1862. These armies were composed of the village farmers, inspired with a strong sense of mission for protecting the Confucian orthodoxy, and were used for wider operations than merely protecting their own villages. The necessary funds for maintaining them were provided initially by local gentry.

The fall of Nanking

The Taiping were gradually beaten down: with the capture of An-ch'ing, the capital of Anhwei, in October 1861 by the Hunan Army, the revolutionary cause was doomed. But the fall of Nanking was accelerated by the cooperation of Chinese mercenaries equipped with Western arms, commanded by an American, Frederick T. Ward; a Briton, Charles G. Gordon; and others. Nanking's fall in July 1864 marked the end of one of the greatest civil wars in world history. The main cause of the Taiping failure was internal strife among the top leaders in Nanking. Not only did they give themselves over to luxury, but also their energy was exhausted and their leadership lost by a fratricidal conflict that occurred in 1856. In addition, religious fanaticism, though it inspired the fighters, became a stumbling block that interfered with the rational and elastic attitude necessary to handle delicate military and administrative affairs. The intolerance toward traditional culture alienated the gentry and the people alike. Presumably, the failure of the land-redistribution policy also estranged the landless paupers from the Taiping cause.

The Nien Rebellion. Often in the first half of the 19th century plundering gangs, called *nien,* ravaged northern Anhwei, southern Shantung, and southern Honan. In mid-century, however, their activities were suddenly intensified, partly by the addition to their numbers of a great many starving people who had lost their livelihood from repeated floods of the Huang Ho in the early 1850s, and partly because they had become emboldened by the Taiping advance north of the Yangtze. From 1856 to 1859 the Nien leaders consolidated their bases north of the Huai River by winning over the masters of the earth-wall communities, consolidated villages that had been fortified for self-defense against the Taiping. The Nien strategy was to use their powerful cavalry to plunder the outlying areas and carry the loot to their home bases.

Many influential clans, with all their members, joined the Nien cause; and among the Nien leaders, the clan chiefs played an important role. Gentry of lower strata also joined the Nien. The greater part of the Nien force consisted of poor peasants, although deserters from the government-recruited militias and salt smugglers were important as military experts. The real cause of their strength was supposed to have been the people's support and sympathy for their leaders; but there was difficulty in creating a power centre, because the Nien's basic social unit was the earth-wall community, where a powerful master exercised autonomy. In 1856 Chang Lo-hsing received the title of "lord of the alliance" of the Nien, but he was far too weak to form a centre. Imperial pacification was launched by Gen. Seng-ko-lin-ch'in, who led a powerful cavalry into the affected area in 1862; but his pursuit was ineffective, and the general himself was killed in Shantung in May 1865. Thus, the last Imperial crack unit disappeared. Tseng Kuo-fan succeeded Seng as general and enforced a

policy of detaching the earth-wall masters from their men and of employing the latter as his troops. Finally, Li Hung-chang succeeded Tseng in 1866 and set up encirclement lines along the Huang Ho and the Grand Canal, by means of which he destroyed the revolts in 1868.

Muslim rebellions. Muslim rebellions in Yunnan and in Shensi and Kansu originated from clashes between the Chinese and Muslims in those provinces. Religious antipathy must be taken into account, but more important were the social and political factors. In the frontier provinces the late dynastic confusions were felt as keenly as elsewhere, which aggravated the problems between the Chinese and the Muslims. Yunnan had been haunted by Muslim-Chinese rivalries since 1821, but in Shensi small disturbances had been seen as early as the Ch'ien-lung reign. Government officials supported the Chinese, and the Muslims were obliged to rise up against both the Chinese and the authorities.

Clashes between Chinese and Muslims

A rivalry between the Chinese and Muslim miners in central Yunnan triggered a severe clash in 1855, which developed into a slaughter of a great many Muslims in and around the provincial capital, K'un-ming, the following April. This caused a general uprising of Yunnan Muslims, which lasted until 1873. Lack of a unified policy weakened the Muslims, and the rebellion was brought to an end partly through the pacifiers' policy of playing the rebel leaders off against one another.

Another Muslim uprising, in Shensi in 1862, promptly spread to Kansu and East Turkistan and lasted for 15 years. The general cause of the trouble was the same as in Yunnan, but the Taiping advance to Shensi stimulated the Muslims into rebellion. The first stage of the uprising developed in the Wei Valley in Shensi; in the next stage the rebels, defeated by the Imperial army, fled to Kansu, which became the main theatre of fighting. Encouraged by the Nien invading Shensi at the end of 1866, the core of the rebel troops returned to Shensi, and sporadic clashes continued in the two provinces. In the last phase, Tso Tsung-t'ang, a former protégé of Tseng Kuo-fan, appeared in Shensi with part of the Huai Army and succeeded in pacifying the area in 1873.

In Shensi and Kansu there were many independent Muslim leaders, but they had neither a common headquarters nor unified policy, and there were no all-out revolutionaries. Pacification was delayed because the Imperial camp was preoccupied with the Taiping and the Nien and could not afford the expenditure needed for an expedition to the remote border provinces.

Effects of the rebellions. To meet the large popular uprisings, the Ch'ing authorities had to rely on local armies, which were financed by the provincial and local gentry class. To meet this need, a special tax on goods in transit (called the likin) was started in 1853, the proceeds of which remained largely outside the control of the central government. The provincial governors-general and governors came to enlarge their military and financial autonomy, bringing about a trend of decentralization. Moreover, the locus of power shifted from the Manchu to those Chinese who had played the main part in putting down the rebellions. The Hunan Army was gradually disbanded after the fall of Nanking; but the Huai Army, after its success against the Muslims, served as a strong basis for the political maneuvers of its leader, Li Hung-chang, until its defeat and collapse in the Sino-Japanese War in 1894–95.

Shift of power away from the Manchu

The rebellions brought immeasurable damage and devastation to China. Both the Taiping and the pacifiers were guilty of brutality and destruction. A contemporary estimate of 20,000,000 to 30,000,000 victims is certainly far less than the real number. In the course of the Taiping Rebellion the lower Yangtze provinces lost much of their surplus population, but thereafter the region was resettled by immigrants from less damaged areas. Its ruined industry and agriculture had not fully recovered even by the beginning of the 20th century. The area of the Muslim rebellions, too, suffered catastrophic devastation and depopulation.

During the first half of the 19th century a number of natural disasters left large hordes of starving victims who had no choice but to join the Taiping and other rebel groups. The worst calamity, however, was a drought that attacked the northern provinces of Shansi, Shensi, and Honan in 1877–78 and caused hardship for 9,000,000 to 13,000,000 people. These disasters were a serious setback to China, which had just begun to promote industrialization to meet the Western challenge.

The Self-Strengthening Movement. Upon the Hsien-feng emperor's death at Cheng-te in 1861, his antiforeign entourage entered Peking and seized power; but Tz'u-hsi, the mother of the newly enthroned boy emperor Tsai-ch'un (reigned as the T'ung-chih emperor, 1861–75), and Prince Kung succeeded in crushing their opponents by a coup d'état in October. There emerged a new system in which the leadership in Peking was shared by Tz'u-hsi and another empress dowager, Tz'u-an, in the palace and by Prince Kung and Wen-hsiang, with the Tsungli Yamen as their base of operation. The core of their foreign policy was expressed by Prince Kung as "overt peace with the Western nations in order to gain time for recovering the exhausted power of the state."

Foreign relations in the 1860s. The Tsungli Yamen had two offices attached to it: the Inspectorate General of Customs and the Language School, called T'ung-wen-kuan. The former was the centre for the Maritime Custom Service, administered by Western personnel appointed by the Ch'ing. The latter was opened to train the children of bannermen in foreign languages, and later some Western sciences were added to its curriculum; but the quality of candidates for the school was not high. Similar schools were opened in Shanghai and Canton.

A superintendent of trade for the three northern ports (later known as high commissioner for *pei-yang,* or "northern ocean") was established in 1861 at Tientsin, parallel to a similar, existing post at Shanghai (later known as high commissioner for *nan-yang,* or "southern ocean"). The creation of the new post was presumably aimed at weakening the foreign representatives in Peking by concentrating foreign affairs in the hands of the Tientsin officials.

In 1865–66 the British strongly urged the Ch'ing authorities to make domestic reforms and to become westernized. Prince Kung asked the high provincial officials to submit their opinions about the proposed reforms. The consensus advocated diplomatic missions abroad and the opening of mines but firmly argued against telegraph and railway construction. Against this background, a roving mission was sent to the United States in 1868, which then proceeded to London and Berlin. This first mission abroad was a success for China, but its very success had an adverse effect on China's modernization by encouraging the conservatives, who learned to regard the Westerners as easy to manipulate.

First mission abroad

The Anglo-Chinese Treaty of Tientsin provided for its revision in the year 1868, at which time the Ch'ing were able to negotiate with due preparations and in a mood of peace for the first time after the Opium Wars. The result was the Alcock Convention of 1869, which limited the unilateral most-favoured-nation clause, a sign of gradual improvement in China's foreign relations; but under pressure from British merchants in China, the London government refused to ratify it. The resentment engendered by the refusal, together with an anti-Christian riot at Tientsin in 1870, brought an end to the climate of Sino-foreign cooperation that had prevailed in the 1860s.

The post-Opium Wars arrangements forced China to remove the ban on Christianity, but the Peking court tried to keep the fact secret and encouraged provincial officials to prohibit the religion. The pseudo-Christian Taiping movement furthered the anti-Christian move on the part of royalists. Under such circumstances, anti-Christian riots had spread throughout the country, culminating in the Tientsin Massacre in 1870, in which a French consul and two officials, 10 nuns, and two priests died, and in which three Russian traders were killed by mistake. At the negotiating table the French sternly demanded the lives of three responsible Chinese officials as a preventive against further such occurrences, but the Ch'ing negotiators, Tseng Kuo-fan and Li Hung-chang, were successful at least in refusing the demanded execution. After the incident, however, Tseng was denounced for his infirm

stand and Prince Kung's political influence began to wane in the growing antiforeign climate.

As to the nature of the anti-Christian movement, there are various interpretations: some emphasize the antiforeign Confucian orthodoxy, while others stress the patriotic and nationalistic reaction against the missionaries' attempt to westernize the Chinese. Still others point to the Christian support of the oppressed in their struggle against the official and gentry class. What is clear, however, is that Christianity sowed dissension and friction in the already disintegrating late Ch'ing society and undermined the prestige of the Ch'ing dynasty and the Confucian orthodoxy.

Industrialization for "self-strengthening." Stimulated by the military training and techniques exhibited during the Westerners' cooperation against the Taiping and supported by Prince Kung in Peking, the Self-Strengthening Movement was launched by the anti-Taiping generals Tseng Kuo-fan, Li Hung-chang, and Tso Tsung-t'ang, who sought to consolidate the Ch'ing power by introducing Western technology. The ideological champion of the movement was Feng Kuei-fen, who urged "the use of the barbarians' superior techniques to control the barbarians" and proposed to give the gentry stronger leadership than before in local administration.

Introduction of Western technology

In the first period of modern industrial development (1861–72), effort was focused on the manufacture of firearms and machines, the most important enterprises being the Kiangnan Arsenal in Shanghai, the Tientsin Machine Factory, and the Fu-chou Navy Yard. There were many other smaller ones. But the output was disappointing—the shipyard at Fu-chou, for example, built 15 vessels during the five years after 1869 as scheduled, but thereafter it declined and was destroyed in 1884 during the Sino-French War—and the weapons industry was significant not so much for its direct military purpose as for the introduction of Western knowledge and techniques through the many educational facilities that were attached to each installation.

In the second period (1872–94), weight shifted from the weapons industry to a wider field of manufacture, and the operation shifted from direct government management to a government-supervised and merchant-managed method. Leading among the several enterprises of the second period were the China Merchants' Steam Navigation Company and the K'ai-p'ing Coal Mines. These enterprises were sponsored by high provincial officials—the central figure was Li Hung-chang—but their management was left to joint operation by shareholders' representatives and the lower officials appointed by the sponsors.

Bureaucratic malpractice and corruption

Management, however, was beset with bureaucratic malpractices. The seat of decision making and responsibility was obscure, business was spoiled by nepotism and corruption, and the sponsors tended to use the enterprises as a basis for their regional power. The central government not only was unable to supply capital but also looked for every opportunity to exploit these enterprises as it had exploited the monopolistic salt business after which those companies were modeled. Under such circumstances, the enterprises inevitably slid into depression after some initial years of apparent success.

Compounding the problems were the compradors (Chinese agents employed by foreign firms in China) who, acting as a link between Chinese commerce and the foreign firms in the treaty ports, accumulated vast wealth from the new enterprises. Though active in supplying capital and managerial personnel to the enterprises, the compradors themselves lacked technical training and knowledge and often indulged in speculation and embezzlement. Each comprador belonged to an exclusive community by strong family or regional ties that focused his concerns on his community rather than on national interests.

These shortcomings were deeply rooted in the late Ch'ing social conditions and more than offset efforts to construct and maintain the new enterprises. Thus, Chinese society as a whole did not change structurally before 1911.

Changes in outlying areas. With the decline of the Ch'ing power and prestige, beginning in the early 19th century, China's peripheral areas began to free themselves from the Ch'ing influence.

East Turkistan. To the west of Kashgaria in East Turkistan, a khanate of Khokand emerged in Ferghana after 1760 as a powerful caravan trade centre. When Muslim rebellion spread rapidly from Shensi and Kansu to East Turkistan, a Khokandian adventurer, Yakub Beg, seized the opportunity to invade Kashgaria and established power there in 1865; he soon showed signs of advancing to the Ili region in support of the British in India. In Ili rebel Muslims had set up an independent power at Kuldja in 1864, which terrorized the Russian borders in defiance of the Sino-Russian Treaty of 1851. The Russians, therefore, occupied Kuldja in 1871 and remained there for 10 years.

Having subdued the Kansu Muslim rebellion in 1873, Tso Tsung-t'ang captured Urumchi (Wu-lu-mu-ch'i) in August 1876 and restored the whole region northward to the Tien Shan range, except for the Kuldja area, and painstakingly recovered Kashgaria at the end of 1877.

Li Hung-chang hoped to regain Ili through negotiation. A treaty for the restitution of Ili, signed at Livadia in October 1879, was extremely disadvantageous to China. Upon returning home amid a storm of condemnation, the Chinese negotiator Ch'ung-hou was sentenced to death; the Russians considered this to be inhuman and they stiffened their attitude. But the minister to Britain and France, Tseng Chi-tse, son of Tseng Kuo-fan, succeeded in concluding a treaty at St. Petersburg in February 1881 that was more favourable yet still conceded the Russians many privileges in East Turkistan.

Establishment of Sinkiang

Though at a cost of nearly 58,000,000 taels in expedition and indemnity, the northwest was finally restored to China, and in 1884 a new province, Sinkiang, was established over the area, which had never before been integrated into China.

Tibet and Nepal. Ch'ing control of Tibet reached its height in 1792. But thereafter China became unable to protect Tibet from foreign invasion. When an army from northern India invaded western Tibet in 1841, China could not afford to reinforce the Tibetans, who expelled the enemy on their own. China was a mere bystander during a coup d'état in Lhasa in 1844 and could not protect Tibet when it was invaded by Gurkhas in 1855. Tibet thus tended to free itself from Ch'ing control.

The border dispute between Nepal and British India, which sharpened after 1801, had caused the Anglo-Nepalese War of 1814–16 and brought the Gurkhas under British influence. During the war the Gurkhas sent several missions to China in vain expectation of assistance. During political unrest in Nepal after 1832, an anti-British clique seized power and sought assistance from China to form an anti-British common front with the Ch'ing, then fighting the Opium War. But this, too, was rejected. Jang Bahadur, who had become premier of Nepal in 1846, decided on a pro-British policy; his invasion of Tibet in 1855—which took advantage of the Taiping uprising in China—gained Nepal many privileges there. Though Nepal sent quinquennial missions to China until 1906, the Gurkhas had not recognized Chinese suzerainty.

Burma. In 1867 the British gained the right to station a commercial agent at Bhamo in Burma, from which they could explore the Irrawaddy River up to the Yunnan border. A British interpreter accompanying a British exploratory mission to Yunnan was killed by local tribesmen on the Yunnan–Burma border in February 1875. The British minister in China, Thomas Wade, seized the opportunity to force China to comply with the Chefoo Convention (1876), which further enlarged the British rights by opening more Chinese ports to foreign trade and agreeing to a mission to delineate the Yunnan–Burmese border, though the London government put off its ratification until 1885. Kuo Sung-tao, appointed chief of a mission of apology to Britain, arrived in London in 1877. He was the first Chinese resident minister abroad, and within two years China opened embassies in five major foreign capitals.

Further enlargement of British rights

When the last king of Burma, Thibaw, tried to join with France and Italy to stave off the British pressure, Britain sent an ultimatum in October 1885, seized the capital of Mandalay, and annexed the country in January 1886. During the final bargaining with the British, the Burmese

king ignored his tributary relations with the Ch'ing; yet China proposed that the Burmese royal court be preserved even nominally so that it could send a decennial mission to China. Britain refused, but in a convention signed in July 1886 it agreed that the Burmese government should send to China a decennial envoy. This outdated practice, however, was buried in 1900.

Vietnam. In 1802 a new dynasty was founded in Vietnam (Dai Viet) by Nguyen Phuc Anh, a member of the royal family of Nguyen at Hue, who had expelled the short-lived Tay Son regime and had unified the country. The Ch'ing, under the Chia-ch'ing emperor, recognized the new dynasty as a fait accompli, but a controversy arose as to a name for the new country. Nguyen Phuc Anh demanded the name Nam Viet, but the Ch'ing recommended Vietnam, reversing the two syllables. Finally an agreement was reached, and Nguyen Phuc Anh became king of Vietnam.

During the rule of the second and third kings of Vietnam (1820–41) the persecution of Christians was accelerated. France resorted to arms after 1843 and, by the treaty of 1862 signed at Saigon, received three eastern provinces of Cochinchina besides other privileges concerning trade and religion. In time, French attentions were focused on the Tongking (Tonkin) delta region into which the Red River flows, providing easy access to Yunnan. But the region was beset with many disorderly gangs escaped from China, including the Black Flags under the command of Liu Yung-fu, a confederate of the Taiping. After a small French force had occupied some key points in Tongking in 1873, a treaty was signed at Saigon in March 1874 that stipulated the sovereignty and independence of Vietnam. Though this clause implied that China could not intervene in Vietnamese affairs, the Tsungli Yamen failed to file a strong protest. In 1880, however, the Ch'ing claimed a right to protect Vietnam as its vassal state. Against the French occupation of Tongking in 1882–83 and France's proclamation of protectorate status for Vietnam (under the name of Annam) in the Treaty of Hue of August 1883, the Ch'ing deployed its army in the northern frontier of Tongking. Efforts for a peaceful settlement ended in failure, and both countries prepared for war.

Sino-French warfare

In August 1884 French warships attacked Fu-chou and destroyed the Chinese fleet and dockyard there. Thereafter, however, the French navy and army were stalemated, and an armistice was reached in the spring of 1885. By the subsequent definitive treaty, the French protectorate of Vietnam was recognized, terminating the historical Sino-Vietnamese tributary relationship.

In this crisis, the attitude of the Ch'ing headquarters fluctuated between advocates of militancy and appeasement. Meanwhile, Li Hung-chang and Tseng Kuo-ch'üan were reluctant to mobilize their *pei-yang* and *nan-yang* navies in accordance with orders from Peking.

Japan and Ryukyu. Three years after the Meiji Restoration of 1868—which inaugurated a period of modernization and political change in Japan—a commercial treaty was signed between China and Japan, and it was ratified in 1873. Understandably it was reciprocal, because both signatories had a similar unequal status vis-à-vis the Western nations. The establishment of the new Sino-Japanese relations was supported by Li Hung-chang and Tseng Kuo-fan, who advocated positive diplomacy toward Japan.

In 1872 the Meiji government conferred on the last king of Ryukyu, Shō Tai, the title of vassal king and in the following year took over the island's foreign affairs. In reprisal for the massacre of shipwrecked Ryukyuans by Taiwanese tribesmen in 1871, the Tokyo government sent a punitive expedition to Taiwan. Meanwhile, the Japanese sent an envoy to Peking to discuss the matter, and the Ch'ing agreed to indemnify Japan. In 1877, however, the Ryukyu king asked for Ch'ing intervention to revive his former tributary relations with China; Sino-Japanese negotiations were opened at Tientsin in regard to Ryukyu's position, and an agreement was reached in 1882. But the Ch'ing refused to ratify it, and the matter was dropped.

Korea and the Sino-Japanese War. In Korea (Chosŏn) a boy king, Kojong, was enthroned in 1864 under the regency of his father, Taewŏn-gun, a vigorous exclusionist. In 1866 they began a nationwide persecution of Christians and repulsed the French and Americans there. The Ch'ing, although uneasy, did not intervene.

After the Meiji Restoration, Japan made many efforts, all in vain, to open new and direct intercourse with Korea. The main reasons for the failure were such trifles as some offensive words in letters addressed by the Japanese government to Korea, or Japanese envoys coming to Korea in Western-style dress, which was unacceptable to the Koreans. With a slightly improved Korean attitude toward foreigners, a Japanese envoy began talks at Pusan in 1875, but the parley was protracted. Japan impatiently sent warships to Korea; these sailed northward to Kanghwa Bay, where gunfire was exchanged between the Japanese vessels and a Korean island fort. The Treaty of Kanghwa was signed in 1876, in which Korea was defined as an independent state on an equal footing with Japan. Japan sent an envoy, Mori Arinori, to China to report on recent Korean affairs. China insisted that though Korea was independent, China could come to the support of its vassal state (Korea) in a crisis, an interpretation that Mori saw as contrary to the idea of independence in international law.

Sino-Japanese competition

From this time on, the Ch'ing strove to increase their influence in Korea; they helped open Korea to the United States and supported the efforts of pro-Chinese Koreans for modernization. But in Korea a powerful conservatism and xenophobia provided the basis for the resurgence of Taewŏn-gun. In July 1882 he expelled Queen Min and her clique and burned down the Japanese legation. The Ch'ing dispatched an army to Korea, arrested Taewŏn-gun, and urged the King to sign a treaty with Japan. Thus, the Ch'ing claim for suzerainty was substantiated.

In December 1884 another coup was attempted by a group of pro-Japanese reformists, but it failed because of the Ch'ing military presence in Korea. From these two incidents Ch'ing political influence and commercial privileges emerged much stronger, though Japan's trade in Korea far surpassed that of China in the late 1880s.

In 1860 a Korean scholar, Ch'oe Che-u, founded a popular religion called Tonghak (Eastern Learning). By 1893 it had turned into a political movement that attracted a vast number of paupers under the banner of antiforeignism and anticorruption. They occupied the southwestern city of Chŏnju in late May 1894. Both China and Japan sent expeditions to Korea, but the two interventionists arrived to find the rebels at Chŏnju already dispersed. To justify its military presence, Japan proposed to China a policy of joint support of Korean reform. When China refused on the ground that this was counter to Korean independence, a clash seemed inevitable. On July 25 the Japanese Navy defeated a Chinese fleet in Kanghwa Bay, and on August 1 both sides declared war. Japan gained victories in every quarter on land and sea.

During the crisis the Ch'ing power centre was again divided. The *pei-yang* navy was less powerful than it appeared, lacking discipline, unified command, and the necessary equipments of a modern navy. In February 1895 Li Hung-chang was appointed envoy to Japan; he signed a peace treaty at Shimonoseki on April 17, whose main items were recognition of Korean independence, indemnity of 200,000,000 taels, and the cession of Taiwan, the Pescadores Islands, and the Liaotung Peninsula. Six days later, however, Russia, Germany, and France forced Japan to restore the peninsula; Japan formally relinquished it on May 5, for which China agreed to pay 30,000,000 taels. Gaining China's favour by this intervention, the three powers began to press China with demands, which gave rise to a veritable scramble for concessions.

Reform and upheaval. Immediately after the triple intervention, Russia succeeded in 1896 in signing a secret treaty of alliance with China against Japan, by which Russia gained the right to construct the Chinese Eastern Railway across northern Manchuria. In November 1897 the Germans seized Chiao-chou Bay in Shantung and forced China to concede them the right to build two railways in the province. In March 1898 Russia occupied Port Arthur (modern Lü-shun) and Dairen (Lü-ta) on the Liaotung Peninsula and obtained the lease of the two ports and the right to build a railway connecting them to the Chinese

The scramble for concessions

Eastern Railway. Vying with Russia and Germany, Britain leased Wei-hai in Shantung and the New Territories opposite Hong Kong and forced China to recognize the Yangtze Valley as being under British influence. Following suit, Japan put the province of Fukien under its influence, and France leased Kuang-chou Bay, southwest of Hong Kong, and singled out three southwestern provinces for its sphere of influence. Thus, China was placed on the brink of partition, arousing a keen sense of crisis in 1898 in which the Hundred Days of Reform was staged.

The Hundred Days of Reform, 1898. The advocates of the Self-Strengthening Movement had regarded any institutional or ideological change as needless. But after 1885 some lower officials and comprador intellectuals began to emphasize institutional reforms and the opening of a parliament and to stress economic rather than military affairs for self-strengthening purposes. For the Peking court and high officials in general the necessity of reform had to be proved on the basis of the Chinese Classics. Some scholars tried to meet their criteria. The outstanding reform leader and ideologist K'ang Yu-wei used what he considered authentic Confucianism and Buddhist canons to show that change was inevitable in history and, accordingly, that reform was necessary. Another important reformist thinker, T'an Ssu-t'ung, relied more heavily on Buddhism than K'ang did and emphasized the people's rights and independence. Liang Ch'i-ch'ao was an earnest disciple of K'ang but later turned toward people's rights and nationalism under the influence of Western philosophy.

In April 1895, when Japanese victory appeared inevitable, K'ang began to advocate institutional reform. In August K'ang, Liang, and other reformists founded a political group called the Society for the Study of National Strengthening. Though this association was soon closed down, many study societies were created in Hunan, Kwangtung, Fukien, Szechwan, and other provinces. In April 1898 the National Protection Society was established in Peking under the slogan of protecting state, nation, and national religion. Against this background, the Kuang-hsü emperor (ruled 1875–1908) was himself increasingly affected by the ideas of reform that were broadly in the air and perhaps was also directly influenced by K'ang Yu-wei's proposals. On June 11, 1898, the Emperor began to issue a stream of radical and probably hastily prepared reform decrees that lasted for about 100 days, until September 20. The reform movement produced no practical results, however. Finally, the conservatives were provoked to a sharp reaction when they learned of a reformists' plot to remove the arch-conservative empress dowager Tz'u-hsi. On September 21 the Emperor was detained and the Empress Dowager took over the administration, putting an end to the reform movement.

Failure of the reform movement

The immediate cause of the failure lay in the power struggle between the Emperor and Tz'u-hsi. But from the beginning, prospects for reform were dim because most high officials were cool toward or opposed to the movement. In addition, the reformist–conservative confrontation overlapped with the rivalry between the Chinese and the Manchu, who considered the Chinese-sponsored reform as disadvantageous to them. As for the reformists themselves, their leaders were few in number and inexperienced in politics, and their plan was too radical.

Among the local movements for reform, that in Hunan was the most active. After 1896, journals and schools were begun there for popular enlightenment; but K'ang's radical reformism aroused strong opposition, and the Hunan movement was shattered at the end of May 1898.

Though it failed, the reform movement had a few important repercussions: it produced some degree of freedom of speech and association, furthered the dissemination of Western thought, and stimulated the growth of private enterprises. It also provided much of the substance for the "conservative" Imperial reform efforts that the Manchu court undertook after the Boxer episode.

The Boxer Rebellion. The crisis of 1896–98 stirred a furious antiforeign uprising in Shantung, aroused by the German advances and encouraged by the provincial governor. It was staged by a band of people called the I-ho ch'üan (Righteous and Harmonious Fists) who believed that a mysterious boxing art rendered them invulnerable to harm. The group's origin is generally supposed to have been in the White Lotus sect, though it may have begun as a self-defense organization during the Taiping Rebellion. At first the Boxers (as they were called in the West) directed their wrath against Christian converts, whom they vilified for having abandoned traditional Chinese customs in favour of an alien religion. Bands of Boxers roamed the countryside killing Chinese Christians and foreign missionaries. Developing from this anti-Christian hysteria, the Boxer Rebellion grew into a naive but furious attempt to destroy all things foreign—including churches, railways, and mines—which the people blamed for their misery and for the loss of a sacred way of life.

Some Boxer recruits were disbanded Imperial soldiers and local militiamen; others were Grand Canal boatmen deprived of a livelihood by the Western-built railways. Most recruits, though, came from the peasantry, which had suffered terribly from recent natural calamities in North China. After 1895 the Huang Ho flooded almost annually, and in 1899–1900 a serious drought struck the North. Vast numbers of starvelings turned to begging and banditry and were easy converts to the Boxers' cause.

Many local authorities refused to stop the violence. Some supported the Boxers by incorporating them into local militias. The Manchu court, meanwhile, was alarmed by the uncontrollable popular uprising but took great satisfaction at seeing revenge taken for its humiliation by the foreign powers. As a result, it assumed at first a neutral policy. On the part of the Boxers, there emerged sometime in the autumn of 1899 a move to gain access to the court under the slogan of "support for the Ch'ing and extermination of foreigners." By May 1900 the Ch'ing government had changed its policy and was secretly supporting the Boxers. Tz'u-hsi inclined toward open war when she became convinced of the dependability of the Boxers' art. Finally, incensed over a false report that the foreign powers had demanded that she return administration to the Emperor, she called on all Chinese to attack foreigners. Within days, on June 20, the Boxers' eight-week siege of the foreign legations in Peking began; a day later Tz'u-hsi declared war by ordering provincial governors to take part in the hostilities.

Government support of the Boxers

An international reinforcement of some 2,000 men had left Tientsin for Peking before the siege, but on the way it was resisted by the Boxers and forced back to Tientsin. The foreign powers then sent an expedition of some 19,000 troops, which marched to Peking and seized the city on August 14. Tz'u-hsi and the Emperor fled to Sian.

The two governors-general in the southeastern provinces, Liu K'un-i and Chang Chih-tung, who together with Li Hung-chang at Canton had already disobeyed Peking's antiforeign decrees, concluded an informal pact with foreign consuls at Shanghai on June 26, to the effect that the governors-general would take charge of the safety of the foreigners under their jurisdiction. At first the pact covered the five provinces in the Yangtze River region, but later it was extended to three coastal provinces. Thus, the foreign operations were restricted to Chihli (modern Hopeh) Province, along the northern coast.

The United States, which had announced its commercial Open Door policy in 1899, made a second declaration of the policy in July 1900—this time insisting on the preservation of the territorial and administrative entity of China. With its newly acquired territory in the western Pacific, the United States was determined to preserve its own commercial interests in China by protecting Chinese territorial integrity from the other major powers. This provided a basis for the Anglo-German agreement (October 1900) for preventing further territorial partition, to which Japan and Russia consented. Thus, partition of China was avoided by mutual restraint among the powers.

The final settlement of the disturbance was signed in September 1901. The indemnity amounted to 450,000,000 taels to be paid over 39 years. Moreover, the settlement demanded the establishment of permanent guards and the dismantling of forts between Peking and the sea, a humiliation that made an independent China a mere fiction. In addition, the southern provinces were actually

Collapse of Ch'ing prestige

independent during the crisis. These occurrences meant the collapse of the Ch'ing prestige.

After the uprising Tz'u-hsi had to declare that she had been misled into war by the conservatives and that the court, neither antiforeign nor antireformist, would promote reforms, a seemingly incredible statement in view of the court's suppression of the 1898 reform movement. But the Ch'ing court's antiforeign conservative nationalism and the reforms undertaken after 1901 were, in fact, among several competing responses to the shared sense of crisis in early 20th-century China.

Early work of Sun Yat-sen

Reformist and revolutionist movements at the end of the dynasty. Sun Yat-sen, a commoner with no background of Confucian orthodoxy, educated in Western-style schools in Hawaii and Hong Kong, went to Tientsin in 1894 to meet Li Hung-chang and present a reform program, but he was refused an interview. This event supposedly caused his antidynastic attitude. Soon he went to Hawaii, where he founded an anti-Manchu fraternity called the Hsing-chung hui (Revive China Society). Returning to Hong Kong, he and some friends set up a similar society under the leadership of his associate Yang Ch'ü-yün. After an abortive attempt to capture Canton in 1895, Sun sailed for England and then went to Japan in 1897, where he found much support. Tokyo became the revolutionaries' principal base of operation.

After the collapse of the Hundred Days of Reform, K'ang Yu-wei and Liang Ch'i-ch'ao had also fled to Japan. An attempt to reconcile the reformists and the revolutionaries became hopeless by 1900—Sun was slighted as a secret-society ruffian, while the reformists were more influential among the Chinese in Japan and the Japanese.

The two camps competed in collecting funds from the overseas Chinese as well as in attracting secret-society members on the mainland. The reformists strove to unite with the powerful secret Ko-lao hui (Society for Brothers and Elders) in the Yangtze River region. In 1899 K'ang's followers organized the Tzu-li chün (Independence Army) at Han-k'ou in order to plan an uprising, but the scheme ended unsuccessfully. Early in 1900 the Revive China Society revolutionaries also formed a kind of alliance with the Brothers and Elders, called the Revive Han Association. This new body nominated Sun as its leader, a decision that also gave him, for the first time, the leadership of the Revive China Society. The Revive Han Association started an uprising at Hui-chou, in Kwangtung, in October 1900, which failed after two weeks' fighting with Imperial forces.

After the Boxer disaster, Tz'u-hsi reluctantly issued a series of reforms, which included abolishing the civil service examination, establishing modern schools, and sending students abroad. But these measures could never repair the damaged Imperial prestige; rather, they inspired more anti-Manchu feeling and raised the revolutionary tide. But there were other factors that intensified the revolutionary cause: the introduction of social Darwinist ideas by Yen Fu after the Sino-Japanese War countered the reformists' theory of change based on the Chinese Classics; and Western and revolutionary thoughts came to be easily and widely diffused through a growing number of journals and pamphlets published in Tokyo, Shanghai, and Hong Kong.

Spread of revolutionary ideas

Nationalists and revolutionists had their most enthusiastic and numerous supporters among the Chinese students in Japan, whose numbers increased rapidly between 1900 and 1906. The Tsungli Yamen sent 13 students to Japan for the first time in 1896; in 10 years the figure rose to some 8,000. Many of these students began to organize themselves for propaganda and immediate action for the revolutionary cause. In 1902–04 revolutionary and nationalistic organizations, including the Chinese Educational Association, the Society for Revival of China, and the Restoration Society, appeared in Shanghai. The anti-Manchu tract "Revolutionary Army" was published in 1903, and more than 1,000,000 copies were issued.

Dealing with the young intellectuals was a new challenge for Sun Yat-sen, who hitherto had concentrated on mobilizing the uncultured secret-society members. He had also to work out some theoretical planks, though he was not a first-class political philosopher. The result of his response was the Three Principles of the People—nationalism, democracy, and socialism—the prototype of which came to take shape by 1903. He expounded his philosophy in America and Europe during his travels there in 1903–05, returning to Japan in the summer of 1905. The activists in Tokyo joined him to establish a new organization called the United League (T'ung-meng hui); under Sun's leadership, the intellectuals increased their importance.

Sun Yat-sen and the United League. Sun's leadership in the league was far from undisputed. His understanding that the support of foreign powers was indispensable for Chinese revolution militated against the anti-imperialist trend of the young intellectuals. Only half-heartedly accepted was the principle of people's livelihood, or socialism, one of his Three Principles. Though various evaluations are given to his socialism, it seems certain that it did not reflect the hopes and needs of the commoners.

Ideologically, the league soon fell into disharmony; Chang Ping-lin, an influential theorist in the Chinese Classics, came to renounce the Three Principles of the People; others deserted to anarchism, leaving anti-Manchuism as the only common denominator in the league. Organizationally, too, the league became divided; a Progressive Society (Kung-chin hui), a parallel to the league, was born in Tokyo in 1907; a branch of this new society was soon opened at Wu-han with the ambiguous slogan of "equalization of human right." The next year Chang Ping-lin tried to revive the Restoration Society.

Effect of the Russo-Japanese War

Constitutional movements after 1905. Japan's victory in the Russo-Japanese War (1904–05) aroused a cry for constitutionalism in China. Unable to resist the intensifying demand, the court decided in September 1906 to adopt a constitution, and in November it reorganized the traditional six boards into 11 ministries in an attempt to modernize the central government. It promised to open consultative provincial assemblies in October 1907 and proclaimed in August 1908 the outline of a constitution and a nine-year period of tutelage before its full implementation.

Three months later the strangely coinciding deaths of Tz'u-hsi and the Emperor were announced, and a boy who ruled as the Hsüan-t'ung emperor (1908–1911/12) was enthroned under the regency of his father, the second Prince Chün. These deaths, followed by that of Chang Chih-tung in 1909, almost emptied the Ch'ing court of prestigious members. The consultative provincial assemblies were convened in October 1910 and became the main base of the furious movement for immediate opening of a consultative national assembly, with which the court could not comply.

The gentry and wealthy merchants were the sponsors of constitutionalism; they had been striving to gain the rights held by foreigners. Started first in Hunan, the so-called rights recovery movement spread rapidly and gained noticeable success, reinforced by local officials, students returned from Japan, and the Peking government. But finally the recovery of the railroad rights ended in a clash between the court and the provincial interests.

The retrieval of the Han-k'ou–Canton line from the American China Development Company in 1905 tapped a nationwide fever for railway recovery and development. But difficulty in raising capital delayed railway construction by the Chinese year after year. The Peking court therefore decided to nationalize some important railways in order to accelerate their construction by means of foreign loans, hoping that the expected railway profits would somehow alleviate the court's inveterate financial plight. In May 1911 the court nationalized the Han-k'ou–Canton and Szechwan–Han-k'ou lines and signed a loan contract with the four-power banking consortium. This incensed the Szechwan gentry, merchants, and landlords who had invested in the latter line, and their anti-Peking remonstrance grew into a provincewide uprising. The court moved some troops into Szechwan from Hupeh; some other troops in Hupeh mutinied and suddenly occupied the capital city, Wu-ch'ang, on October 10, now the memorial day of the Chinese Revolution.

The commoners' standard of living, which had not continued to grow in the 19th century and may have begun to deteriorate, was further dislocated by the mid-century

civil wars and foreign commercial and military penetration. Paying for the wars and their indemnities certainly increased the tax burden of the peasantry, but how serious a problem this was is still an open question. The Manchu reforms and preparations for constitutionalism added a further fiscal exaction for the populace, which benefited very little from these urban-oriented developments. Rural distress, resulting from this and from natural disasters, was among the causes of local peasant uprisings in the Yangtze River region in 1910 and 1911 and of a major rice riot at Ch'ang-sha, the capital of Hunan, in 1910. But popular discontent was limited and not a major factor contributing to the revolution that ended the Ch'ing dynasty and inaugurated the republican era in China.

Burden of the tax-paying commoners

The Chinese Revolution (1911–12). The Chinese Revolution was not triggered by the United League itself but by the Hupeh army troops urged on by the local revolutionary bodies not incorporated in the league. An accidental exposure of a mutinous plot forced a number of junior officers to choose between arrest or revolt in Wu-han. The revolt was initially successful because of the determination of lower-level officers and revolutionary troops and the cowardice of the responsible Manchu and Chinese officials. Within a day the rebels had seized the arsenal and the governor-general's offices and had gained possession of the provincial capital, Wu-ch'ang. With no nationally known revolutionary leaders on hand, the rebels coerced a colonel, Li Yüan-hung, to assume military command, although only as a figurehead. They persuaded the Hupeh provincial assembly to proclaim the establishment of the Chinese republic; T'ang Hua-lung, the assembly's chairman, was elected head of the civil government.

After this initial victory, a number of historical tendencies converged to bring about the downfall of the Ch'ing dynasty. A decade of revolutionary organization and propaganda paid off in a sequence of supportive uprisings in important centres of central and South China; these occurred in recently formed military academies and in newly created divisions and brigades, in which many cadets and junior officers were revolutionary sympathizers. Secret-society units also were quickly mobilized for local revolts. The antirevolutionary constitutionalist movement also made an important contribution; its leaders had become disillusioned with the Imperial government's unwillingness to speed the process of constitutional government, and a number of them led their respective provincial assemblies to declare their provinces independent of Peking or actually to join the new republic. T'ang Hua-lung was the first among them. As a product of the newly emerging nationalism, there was widespread hostility among Chinese toward the alien dynasty. Many had absorbed the revolutionary propaganda that blamed a weak and vacillating court for the humiliations China had suffered from foreign powers since 1895. Therefore, there was a broad sentiment in favour of ending Manchu rule. Also, as an outcome of two decades of journalizing discussion of "people's rights," there was substantial support among the urban educated for a republican form of government. Probably the most decisive development was the recall of Yüan Shih-k'ai, the architect of the elite Peiyang Army, to government service to suppress the rebellion when its seriousness became apparent.

After the collapse of the Huai Army in the Sino-Japanese War, the Ch'ing government had striven to build up a new Western-style army, among which the elite corps trained by Yüan Shih-k'ai, former governor-general of Chihli, had survived the Boxer uprising and emerged as the strongest force in China. But it was, in a sense, Yüan's private army and did not easily submit to the Manchu court. Yüan had been retired from officialdom at odds with the regent prince Chün; but, on the outbreak of the revolution in 1911, the court had no choice but to recall him from retirement to take command of his new army. Instead of using force, however, he played a double game—on the one hand, he deprived the floundering court of all its power; on the other, he started to negotiate with the revolutionaries. At the peace talks that opened at the end of the year, Yüan's emissaries and the revolutionary representatives agreed that the abdication of the Ch'ing and the appointment of Yüan to the presidency of the new republic were to be formally decided by the National Assembly. But this was renounced by Yüan, probably because he hoped to be appointed by the retiring Manchu monarch to organize a new government rather than nominated as chief of state by the National Assembly. (This is a formula of the Chinese dynastic revolution called *ch'an-jang,* which means the peaceful shift in rule from a decadent dynasty to a more virtuous one.) But events turned against him, and the presidency was given to Sun Yat-sen, who had been appointed provisional president of the republic by the National Assembly. In February 1912 Sun Yat-sen voluntarily resigned his position, and the Ch'ing court proclaimed the decree of abdication, which included a passage—fabricated and inserted by Yüan into this last Imperial document—purporting that the latter was to organize a republican government to negotiate with the revolutionists on unification of North and South. Thus ended the 268-year rule of the Manchus. (C.Su./A.Fe.)

Dissolution of the Manchu Court

End of the Ch'ing dynasty

The republican period

THE DEVELOPMENT OF THE REPUBLIC (1912–20)

The first half of the 20th century saw the gradual disintegration of the old order in China and the turbulent preparation for a new society. Foreign political philosophies undermined the traditional governmental system, nationalism became the strongest activating force, and civil wars and Japanese invasion tore the vast country and retarded its modernization. Although the revolution ushered in a republic, China had virtually no preparation for democracy. A three-way settlement ended the revolution—abdication by the dynasty; relinquishment of the provisional presidency by Sun Yat-sen in favour of Yüan Shih-k'ai, regarded as the indispensable man to restore unity; and Yüan's promise to establish a republican government. This placed at the head of state an autocrat by temperament and training, and the revolutionaries had only a minority position in the new national government.

Early power struggles. During the first years of the republic there was a continuing contest between Yüan and the former revolutionaries over where ultimate power should lie. The contest began with the election of parliament (National Assembly) in February 1913. The Nationalist Party (Kuomintang; KMT), made up largely of former revolutionaries, won a commanding majority of seats. Parliament was to produce a permanent constitution. Sung Chiao-jen, the main organizer of the KMT's electoral victory, advocated executive authority in a cabinet responsible to parliament rather than to the president. On March 20, 1913, Sung was assassinated; the confession of the assassin and later circumstantial evidence strongly implicated the Premier and, possibly, Yüan himself.

Yüan versus parliament

Parliament tried to block Yüan's effort to get a "reorganization loan" (face value $125,000,000) from a consortium of foreign banks, but in April Yüan concluded the negotiations and received the loan. He then dismissed three Nationalist military governors. That summer, revolutionary leaders organized a revolt against Yüan, later known as the Second Revolution, but his military followers quickly suppressed it. Sun Yat-sen, one of the principal revolutionaries, fled to Japan. Yüan then coerced parliament into electing him formally to the presidency, and he was inaugurated on October 10, the second anniversary of the outbreak of the revolution. By then his government had been recognized by most foreign powers. When parliament promulgated a constitution placing executive authority in a cabinet responsible to the legislature, Yüan revoked the credentials of the KMT members, charging them with involvement in the recent revolt. He dissolved parliament on Jan. 10, 1914, and appointed another body to prepare a constitution according to his own specifications. The presidency had become a dictatorship.

China in World War I. *Japanese gains.* With the outbreak of World War I, in August 1914, Japan joined the side of the Allies and seized the German leasehold around Chiao-chou Bay together with German-owned railways in Shantung. China was not permitted to interfere. Then, on Jan. 18, 1915, the Japanese government secretly pre-

sented to Yüan the Twenty-one Demands, which sought, in effect, to make China a Japanese dependency. Yüan skillfully directed the negotiations by which China tried to limit its concessions, which centred around greater access to Chinese ports and railroads and even a voice in Chinese political and police affairs. At the same time Yüan searched for foreign support. The European powers, locked in war, were in no position to restrain Japan. The United States was unwilling to intervene. The Chinese public, however, was aroused. Most of Yüan's political opponents supported his resistance to Japan's demands. Nevertheless, on May 7 Japan gave Yüan a 48-hour ultimatum, forcing him to accept the terms as they stood at that point in the negotiations.

Japan gained extensive special privileges and concessions in Manchuria and confirmation of its gains in Shantung from Germany. The Han-yeh-p'ing mining and metallurgical enterprise in the middle Yangtze Valley was to become a joint Sino-Japanese company. China promised not to alienate to any other power any harbour, bay, or island on the coast of China nor to permit any nation to construct a dockyard, coaling station, or naval base on the coast of Fukien, the province nearest to Japan's colony of Taiwan.

Yüan's attempts to become emperor. In the wake of the humiliation of these forced concessions, Yüan launched a movement to revive the monarchy, with some modernized features, and to place himself on the throne. The Japanese government began to "advise" against this move in October and induced its allies to join in opposing Yüan's plan. Additional opposition came from the leaders of the Nationalist and Progressive parties. In December, Ch'en Ch'i-mei and Hu Han-min, two followers of Sun Yat-sen, who was actively scheming against Yüan from his exile in Japan, began a movement against the monarchy. More significant was a military revolt in Yunnan, led by Gen. Ts'ai O, a disciple of Liang Ch'i-ch'ao, and by the governor of Yunnan, T'ang Chi-yao. Joined by Li Lieh-chün and other revolutionary generals, they established a Hu-kuo chün (National Protection Army) and demanded that Yüan cancel his plan. When he would not, the Yunnan army in early January 1916 invaded Szechwan, and subsequently Hunan and Kwangtung, hoping to bring the southwestern and southern provinces into rebellion and then induce the lower Yangtze provinces to join them. The Japanese government covertly provided funds and munitions to Sun and the Yunnan leaders. One by one military leaders in Kweichow, Kwangsi, and parts of Kwangtung declared the independence of their provinces or districts. By March the rebellion had assumed serious dimensions, and public opinion was running strongly against Yüan.

Opposition to Yüan's enthronement

A third source of opposition came from Yüan's direct subordinates, generals Tuan Ch'i-jui and Feng Kuo-chang, whose powers Yüan had attempted to curtail. When he called upon them for help, they both withheld support. On March 22, with the tide of battle running against his forces in the southwest, Japanese hostility increasingly open, public opposition in full cry, and his closest subordinates advising peace, Yüan announced the abolition of the new empire. His opponents, however, demanded that he give up the presidency as well. The revolt continued to spread, with more military leaders declaring the independence of their provinces. The issue became that of succession should Yüan retire. The president, however, became gravely ill; he died on June 6 at the age of 56.

Yüan's four years had serious consequences for China. The country's foreign debt was much enlarged, and a precedent had been established of borrowing for political purposes. Yüan's defiance of constitutional procedures and his dissolution of parliament also set precedents that were later repeated. There was much disillusionment with the republican experiment; China was a republic in name, but arbitrary rule based upon military power was the political reality. The country was becoming fractured into competing military satrapies—the beginning of warlordism.

Gen. Li Yüan-hung, the vice president, succeeded to the presidency, and Gen. Tuan Ch'i-jui continued as premier, a position he had accepted in April. A man of great ability and ambition, Tuan was supported by many generals of the former Peiyang Army, a powerful force based in North China that developed originally under Yüan's leadership. Tuan quickly began to gather power into his own hands. Li favoured the restoration of parliament and a return to the provisional constitution of 1912. Parliament reconvened on August 1; it confirmed Tuan as premier but elected Gen. Feng Kuo-chang, the leader of another emerging faction of the Peiyang Army, as vice-president. The presidential transition and restoration of parliament had by no means answered the underlying question of where the governing power lay.

Conflict over entry into the war. In February 1917 the U.S. government severed diplomatic relations with Germany and invited the neutral powers, including China, to do the same. This brought on a crisis in the Chinese government. Li opposed the step, but Tuan favoured moving toward entry into the war. Parliamentary factions and public opinion were bitterly divided. Sun Yat-sen, now in Shanghai, argued that entering the war could not benefit China and would create additional perils from Japan. Under heavy pressure, parliament voted to sever diplomatic relations with Germany, and Li was compelled by his premier to acquiesce. When the United States entered the war in April, Tuan wished China to do the same but was again opposed by the President.

Tuan and his supporters demanded that China enter the war and that Li dissolve parliament. On May 23, Li dismissed Tuan; he then called upon Gen. Chang Hsün, a power in the Peiyang clique and also a monarchist, to mediate. As a price for mediation, Chang demanded that Li dissolve parliament, which he did reluctantly on June 13. The next day Chang entered Peking with an army and set about to restore the Ch'ing dynasty. Telegrams immediately poured in from military governors and generals denouncing Chang and the coup; Li refused to sign the restoration order and called upon Tuan to bring an army to the capital to restore the republic. Li requested that Vice President Feng assume the duties of president during the crisis and then took refuge in the Japanese legation. Tuan captured Peking on July 14; Chang fled to asylum in the Legation Quarter. Thus ended a second attempt to restore the Imperial system.

Attempt at Manchu restoration

Tuan resumed the premiership, and Feng came to Peking as acting president, bringing a division as his personal guard. The two powerful rivals, each supported by an army in the capital, formed two powerful factions—the Chihli clique under Feng and the Anhwei clique under Tuan. Opposed neither by Li nor by the dissolved parliament, Tuan pushed through China's declaration of war on Germany, announced on Aug. 14, 1917.

Formation of a rival southern government. Meanwhile, in July Sun Yat-sen, supported by part of the Chinese navy and followed by some 100 members of parliament, attempted to organize a rival government in Canton. The initial costs of this undertaking, termed the Movement to Protect the Constitution, probably were supplied by the German consulate in Shanghai. On August 31 the rump parliament in Canton established a military government and elected Sun commander in chief. Real power, however, lay with military men, who only nominally supported Sun. The southern government declared war on Germany on September 26 and unsuccessfully sought recognition from the Allies as the legitimate government. A Hu-fa chün (Constitution Protecting Army) made up of southern troops launched a punitive campaign against the government in Peking and succeeded in pushing northward through Hunan. Szechwan also was drawn into the fight. Tuan tried to quell the southern opposition by force, while Feng advocated a peaceful solution. Tuan resigned and mustered his strength to force Feng to order military action; Gen. Ts'ao K'un was put in charge of the campaign and drove the Southerners out of Hunan by the end of April 1918. In May the southern government was reorganized under a directorate of seven, in which military men dominated. Sun therefore left Canton and returned to Shanghai. Although his first effort to establish a government in the South had been unsuccessful, it led to a protracted split between South and North.

Wartime changes. Despite limited participation, China

made some gains from its entry into the war, taking over the German and Austrian concessions and canceling the unpaid portions of the Boxer indemnities due its enemies. It was also assured a seat at the peace conference. Japan, however, extended its gains in China. The Peking government, dominated by Tuan after Feng's retirement, granted concessions to Japan for railway building in Shantung, Manchuria, and Mongolia. These were in exchange for the Nishihara loans, amounting to nearly $90,000,000, which went mainly to strengthen the Anhwei clique with arms and cash. Japan also made secret agreements with its allies to support its claims to the former German rights in Shantung and also induced the Peking government to consent to these. In November 1917 the United States, to adjust difficulties with Japan, entered upon the Lansing–Ishii Agreement, which recognized that because of "territorial propinquity . . . Japan has special interests in China." This seemed to underwrite Japan's wartime gains.

Important economic and social changes occurred during the first years of the republic. With the outbreak of the war, foreign economic competition with native industry abated and native-owned light industries developed markedly. By 1918 the industrial labour force numbered some 1,750,000. Modern-style Chinese banks increased in number and expanded their capital.

The rise of a new intelligentsia

Intellectual movements. A new intelligentsia had also emerged. The educational reforms and the ending of the governmental examination system during the final Ch'ing years enabled thousands of young people to study sciences, engineering, medicine, law, economics, education, and military skills in Japan. Others went to Europe and the United States. Upon their return they took important positions and were a modernizing force in society. Their writing and teaching became a powerful influence on upcoming generations of students. In 1915–16 there were said to be nearly 130,000 new-style schools in China with more than 4,000,000 students. This was mainly an urban phenomenon, however; rural life was barely affected except for what may have been a gradual increase in tenancy and a slow impoverishment that sent rural unemployed into cities and the armies or into banditry.

An intellectual revolution. An intellectual revolution took place during the first decade of the republic, sometimes referred to as the New Culture Movement. It was led by many of the new intellectuals, who held up for critical scrutiny nearly all aspects of Chinese culture and traditional ethics. Guided by concepts of individual liberty and equality, a scientific spirit of inquiry, and a pragmatic approach to the nation's problems, they sought a much more profound reform of China's institutions than had resulted from self-strengthening or the republican revolution. They directed their efforts particularly to China's educated youth.

In September 1915 Chen Duxiu (Ch'en Tu-hsiu), who had studied in Japan and France, founded *Hsin ch'ing-nien* ("New Youth") magazine to oppose Yüan's Imperial ambitions and to regenerate the nation's youth. This quickly became the most popular reform journal, and in 1917 it began to express the iconoclasm of new faculty members in Peking University (Pei-ta), which Chen had joined as dean of the College of Letters. Peking University, China's most prestigious institution of higher education, was being transformed by its new chancellor, Ts'ai Yüan-p'ei, who had spent many years in advanced study in Germany. Ts'ai made the university a centre of scholarly research and inspired teaching. The students were quickly swept into the New Culture Movement. A proposal by Hu Shih, a former student of John Dewey, that literature be written in the vernacular language (*pai-hua*) rather than in classical style won quick acceptance. By 1918 most of the contributors to *Hsin ch'ing-nien* were writing in *pai-hua,* and other journals and newspapers soon followed suit. Students at Peking University began their own reform journal, *Hsin ch'ao* ("New Tide"). A new experimental literature inspired by Western forms became highly popular, and scores of new literary journals were founded.

Riots and protests. On May 4, 1919, patriotic students in Peking protested the decision at the Versailles Peace Conference that Japan should retain defeated Germany's rights and possessions in Shantung. Many students were arrested in the rioting that followed. Waves of protest spread throughout the major cities of China. Merchants closed their shops, banks suspended business, and workers went on strike to pressure the government. Finally, the government was forced to release the arrested students, to dismiss some officials charged with being tools of Japan, and to refuse to sign the Treaty of Versailles. This outburst helped spread the iconoclastic and reformist ideas of the intellectual movement, which was renamed the May Fourth Movement. By the early 1920s China was launched on a new revolutionary path.

The May Fourth Movement

THE INTERWAR YEARS (1920–37)

Beginnings of a national revolution. This new revolution was led by the Nationalist Party (KMT) and the Chinese Communist Party (CCP).

The Nationalist Party. The Nationalist Party had its origins in the earlier United League (T'ung-meng hui) against the Manchu. The name Nationalist Party was adopted in 1912. After the suppression of this expanded party by Yüan Shih-k'ai, elements from it were organized by Sun Yat-sen in 1914 into the Chinese Revolutionary Party, which failed to generate widespread support. Sun and a small group of veterans were stimulated by the patriotic upsurge of 1919 to rejuvenate this political tradition, as well as to revive the Nationalist Party name. The party's publications took on new life as the editors entered the current debates on what was needed to "save China." Socialism was popular among Sun's followers.

The formation of an effective party took several years, however. Sun returned to Canton from Shanghai late in 1920, when Gen. Ch'en Chiung-ming drove out the Kwangsi militarists. Another rump parliament elected Sun president of a new southern regime, which claimed to be the legitimate government of China. In the spring of 1922 Sun attempted to launch a northern campaign as an ally of the Manchurian warlord, Chang Tso-lin, against the Chihli clique, which by now controlled Peking. Ch'en, however, did not want the provincial revenues wasted in internecine wars. One of Ch'en's subordinates drove Sun from the presidential residence in Canton on the night of June 15–16, 1922. Sun took refuge with the southern navy, and he retired to Shanghai on August 9. He was able to return to Canton in February 1923; he then began to consolidate a base under his own control and to rebuild his party.

The Chinese Communist Party. The CCP grew directly from the May Fourth Movement. Its leaders and early members were professors and students who came to believe that China needed a social revolution and who began to see Soviet Russia as a model. Chinese students in Japan and France had earlier studied socialist doctrines and the ideas of Karl Marx, but the Russian Revolution of 1917 stimulated a fresh interest in keeping with the enthusiasm of the period for radical ideologies. Li Dazhao (Li Ta-chao), the librarian of Peking University, and Chen Duxiu were the CCP's cofounders.

In March 1920 word reached China of Soviet Russia's revolutionary foreign policy enunciated in the first Karakhan Manifesto, which promised to give up all special rights gained by tsarist Russia at China's expense and to return the Russian-owned Chinese Eastern Railway in Manchuria without compensation. The contrast between this promise and the Versailles award to Japan that had touched off the 1919 protest demonstrations could hardly have been more striking. Although the Soviet government later denied such a promise and attempted to regain control of the railway, the impression of this first statement and the generosity still offered in a more diplomatic second Karakhan Manifesto of September 1920 left a favourable image of Soviet foreign policy among Chinese patriots.

Russian influence

Russia set up an international Communist organization, the Comintern, in 1919 and sent Grigory N. Voytinsky to China the next year. Voytinsky met Li Dazhao in Peking and Chen Duxiu in Shanghai, and they organized a Socialist Youth League, laid plans for a Communist Party, and started recruiting young intellectuals. By the spring of 1921 there were about 50 members in various Chinese

cities and in Japan, many of them former students who had been active in the 1919 demonstrations. Mao Zedong (Mao Tse-tung), a protégé of Li Dazhao, had started one such group in Ch'ang-sha. The CCP held its First Congress in Shanghai in July 1921, with 12 or 13 attendants and with a Dutch Communist—Hendricus Sneevliet, who used his Comintern name, Maring, in China—and a Russian serving as advisers. Maring had become head of a new bureau of the Comintern in China, and he had arrived in Shanghai in June 1921. At the First Congress Chen Duxiu was chosen to head the party.

The CCP spent the next two years in recruiting, in publicizing Marxism and the need for a national revolution directed against foreign imperialism and Chinese militarism, and in organizing unions among railway and factory workers. Maring was instrumental in bringing the KMT and the CCP together in a national revolutionary movement. A number of young men were sent to Russia for training. Among the CCP members were many students who had worked and studied in France, where they had gained experience in the French labour movement and with the French Communist Party; Zhou Enlai (Chou En-lai) was one of these. Other recruits were students influenced by the Japanese Socialist movement. By 1923 the party had some 300 members, with perhaps 3,000 to 4,000 in the ancillary Socialist Youth League.

Communist-Nationalist cooperation. By then, however, the CCP was in serious difficulty. The railway unions had been brutally suppressed, and there were few places in China where it was safe to be a known Communist. In June 1923 the Third Congress of the CCP met in Canton, where Sun Yat-sen provided a sanctuary. After long debate this congress accepted the Comintern strategy pressed by Maring—that Communists should join the KMT and make it the centre of the national revolutionary movement. Sun had rejected a multiparty alliance but had agreed to admit Communists to his party, and several, including Chen Duxiu and Li Dazhao, had already joined the KMT. Even though Communists would enter the other party as individuals, the CCP was determined to maintain its separate identity and autonomy and to attempt to control the labour union movement. The Comintern strategy called for a period of steering the Nationalist movement and building a base among the Chinese masses, followed by a second stage—a socialist revolution in which the proletariat would seize power from the capitalist class.

By mid-1923 the Soviets had decided to renew the effort to establish diplomatic relations with the Peking government. Lev M. Karakhan, the deputy commissar for foreign affairs, was chosen as plenipotentiary for the negotiations. In addition to negotiating a treaty of mutual recognition, Karakhan was to try to regain for the Soviet Union control of the Chinese Eastern Railway. On the revolutionary front, the Soviets had decided to financially assist Sun in Canton and to send a team of military men to help train an army in Kwangtung. By June, five young Soviet officers were in Peking for language training. More importantly, the Soviet leaders selected an old Bolshevik, Mikhail M. Borodin, as their principal adviser to Sun Yat-sen. The Soviet leaders also decided to replace Maring with Voytinsky as principal adviser to the CCP, which had its headquarters in Shanghai. Thereafter three men—Karakhan in Peking, Borodin in Canton, and Voytinsky in Shanghai—were the field directors of the Soviet effort to bring China into the anti-imperialist camp of "world revolution." The offensive was aimed primarily at the positions in China of Great Britain, Japan, and the United States.

The arrival of Soviet advisers

Reactions to warlords and foreigners. These states, too, were moving toward a new, postwar relationship with China. At the Washington Conference (November 1921–February 1922), eight powers agreed to respect the sovereignty, independence, and territorial and administrative integrity of China, to give China opportunity to develop a stable government, to maintain the principle of equal opportunity in China for the commerce and industry of all nations, and to refrain from taking advantage of conditions in China to seek exclusive privileges. The powers also agreed to steps leading toward China's tariff autonomy and to the abolition of extraterritoriality. Japan agreed separately to return the former German holdings in Shantung, although under conditions that left Japan with valuable privileges in the province. For a few years thereafter Great Britain, Japan, the United States, and France attempted to adjust their conflicting interests in China, cooperated in assisting the Peking government, and refrained, on the whole, from aiding particular Chinese factions in the recurrent power struggles. But China was in turmoil, with regional militarism in full tide. Furthermore, a movement against the "unequal treaties" (see below) began to take shape.

Militarism in China. During the first years of the republic China had been fractured by rival military regimes to the extent that no one authority was able to subordinate all rivals and create a unified and centralized political structure. The South was detached from Peking's control; but even the southern provinces, and indeed districts within them, were run by different military factions (warlords). Szechwan was a world in itself, divided among several military rulers. The powerful Peiyang Army had split into two major factions whose semi-independent commanders controlled provinces in the Yangtze Valley and in the North; these factions competed for control of Peking. In Manchuria, Chang Tso-lin headed a separate Fengtien army. Shansi was controlled by Yen Hsi-shan. Each separate power group had to possess a territorial base from which to tax and recruit. Arms were produced in many scattered arsenals. Possession of an arsenal and control of ports through which foreign-made arms might be shipped were important elements of power. Most of the foreign powers had agreed in 1919 not to permit arms to be smuggled into China, but this embargo was not entirely effective.

The rival military regimes of republican China

The richer the territorial base, the greater the potential power of the controlling faction. Peking was the great prize because of its symbolic importance as the capital and because the government there regularly received revenues collected by the Maritime Customs Service, administered by foreigners and protected by the powers. Competition for bases brought on innumerable wars, alliances, and betrayals. Even within each military system there was continuous conflict over spoils. To support their armies and conduct their wars, military commanders and their subordinates taxed the people heavily. Money for education and other government services was drained away; revenues intended for the central government were retained in the provinces. Regimes printed their own currency and forced "loans" from merchants and bankers. This chaotic situation partly accounts for the unwillingness of the maritime powers to give up the protection that the treaties with China afforded their nationals.

The foreign presence. As a result of several wars and many treaties with China since 1842, foreign powers had acquired a variety of unusual privileges for their nationals. These were specified in the "unequal treaties," which patriotic Chinese bitterly opposed. Hong Kong, Taiwan, and vast areas in Siberia and Central Asia had been detached from China. Dependencies such as Korea, Outer Mongolia, Tibet, and Vietnam had been separated. Leaseholds on Chinese territory were granted to separate powers—such as the southern part of the Liaotung Peninsula and the territory in Shantung around Chiao-chou Bay, which Japan had seized from Germany, to Japan; the New Territories to the adjacent British Crown Colony of Hong Kong; and the Kuang-chou Bay area to France. In most major cities there were concession areas, not governed by China, for the residence of foreigners. Nationals and subjects of the "treaty powers" were protected by extraterritoriality (*i.e.,* they were subject only to the civil and criminal laws of their own countries); this extended to foreign business enterprises in China, providing a great advantage in competition with Chinese firms, which was enhanced when foreign factories or banks were located in concession areas under foreign protection. The Chinese had to compete with foreign ships in Chinese rivers and coastal waters, with foreign mining companies in the interior, and with foreign banks that circulated their own notes. Foreign trade also had a great advantage because there could be no protective tariff to favour Chinese products.

Christian missionaries operated many schools, hospitals, and other philanthropic enterprises in China, all protected by extraterritoriality. The separate school system, outside of Chinese governmental control, was a sore point for nationalists, who regarded the education of Chinese youth as a Chinese prerogative. There were bodies of foreign troops on Chinese soil and naval vessels in its rivers and ports to enforce treaty rights. Bound by a variety of interlocking treaties, the Chinese government was not fully sovereign in China. Past regimes had accumulated a vast foreign debt against which central government revenues were pledged for repayment. All this was the foreign imperialism against which the KMT launched its attack after being reorganized along Bolshevist lines.

Reorganization of the KMT. The KMT held its First National Congress in Canton on Jan. 20–30, 1924. Borodin, who had reached Canton in October 1923, began to advise Sun in the reorganization of his party. He prepared a constitution and helped draft a party program as a set of basic national policies. Delegates from throughout China and from overseas branches of the party adopted the program and the new constitution. The program announced goals of broad social reform and a fundamental readjustment of China's international status. Its tone was nationalistic; it identified China's enemies as imperialism and militarism. It singled out farmers and labourers as classes for special encouragement but also appealed to intellectuals, soldiers, youth, and women. It threatened the position of landlords in relation to tenants and of employers in relation to labour. Western privileges were openly menaced.

KMT goals

The constitution described a centralized organization, modeled on the Soviet Communist Party, with power concentrated in a small, elected group and with a descending hierarchy of geographical offices controlled by executive committees directed from above. Members were pledged to strict discipline and were to be organized in tight cells. Where possible they were to penetrate and try to gain control of such other organizations as labour unions, merchant associations, schools, and parliamentary bodies at all levels. Sun was designated as leader of the party and had veto rights over its decisions. The congress elected a central executive committee and a central supervisory committee to manage party affairs and confirmed Sun's decision to admit Communists, though this was opposed by numerous party veterans, who feared the KMT itself might be taken over. A few Communists, including Li Dazhao, were elected to the executive committee.

Organization of the executive committee

The executive committee set up a central headquarters in Canton. It also decided to strengthen the party throughout the country by deputizing most of its leaders to manage regional and provincial headquarters and by recruiting new members. A military academy was planned for training a corps of young officers, loyal to the party, who would become lower level commanders in a new national revolutionary army that was to be created. Borodin provided funds for party operations, and the Soviet Union promised to underwrite most of the expenses of, and to provide training officers for, the military academy. Chiang Kai-shek was chosen to be the first commandant of the academy and Liao Chung-k'ai to be the party representative, or chief political officer.

From February to November 1924 Sun and his colleagues had some success in making the KMT's influence felt nationally; they also consolidated the Canton base, although it was still dependent upon mercenary armies. The military academy was set up at Whampoa, on an island south of Canton, and the first group of some 500 cadets was trained. In September Sun began another northern campaign in alliance with Chang Tso-lin against Ts'ao K'un and Wu P'ei-fu, who now controlled Peking. The campaign was interrupted, however, when Wu's subordinate, Feng Yü-hsiang, betrayed his chief and seized Peking on October 23, while Wu was at the front facing Chang Tso-lin. Feng and his fellow plotters invited Sun to Peking to participate in the settlement of national affairs, while Feng and Chang invited Tuan Ch'i-jui to come out of retirement and take charge of the government. Sun accepted the invitation and departed for the North on November 13. Before he arrived in Peking, however, he fell gravely ill with incurable cancer of the liver. He died in Peking on March 12, 1925.

Struggles within the two-party coalition. After Sun's death the KMT went through a period of inner conflict, although it progressed steadily, with Russian help, in bringing the Kwangtung base under its control. The conflict was caused primarily by the radicalization of the party under the influence of the Communists. They organized labour unions and peasant associations and pushed class struggle and the anti-imperialist movement.

Clashes with foreigners. On May 30, 1925, patriotic students, engaged in an anti-imperialist demonstration in Shanghai, clashed with foreign police. The British captain in charge ordered the police to fire upon a crowd that he believed was about to rush his station. Some 12 Chinese were killed in the May Thirtieth Incident, including students. This aroused a nationwide protest and set off a protracted general strike in Shanghai. A second incident occurred on June 23, when French and British marines exchanged fire with Whampoa cadets who were part of an anti-imperialist parade, killing 52 Chinese, many of them civilians, and wounding at least 117; which side had fired first became a matter of dispute. This set off a strike and boycott against Britain, France, and Japan, which was later narrowed to Britain alone. The strike and boycott, led mainly by Communists, lasted for 16 months and seriously affected British trade. These incidents intensified hostility toward foreigners and their special privileges, enhanced the image of the Soviet Union, and gained support for the KMT, which promised to end the unequal treaties. By January 1926 the KMT could claim some 200,000 members. The CCP's membership grew from less than 1,000 in May 1925 to about 10,000 by the end of that year.

Strikes and boycotts against foreigners

KMT opposition to radicals. The two parties competed for direction of nationalist policy, control of mass organizations, and recruitment of new members. Under Comintern coaching, the Communist strategy was to try to split the KMT, drive out its conservative members, and turn it to an ever more radical course. In August 1925, KMT conservatives in Canton tried to stop the leftward trend. One of the strongest advocates of the Nationalists' Soviet orientation, Liao Chung-k'ai, was assassinated. In retaliation, Borodin, Chiang Kai-shek, and Wang Ching-wei deported various conservatives. A group of KMT veterans in the North then ordered the expulsion of Borodin and the Communists and the suspension of Wang Ching-wei; they set up a rival KMT headquarters in Shanghai. The left-wing leaders in Canton then held a Second National Congress in January 1926, confirming the radical policies and the Soviet alliance. But as the Soviet presence became increasingly overbearing, as the Canton–Hong Kong strike and boycott dragged on, and as class conflict intensified in the South, opposition to the radical trend grew stronger, particularly among military commanders.

Rise of Chiang Kai-shek

Chiang Kai-shek, now commander of the National Revolutionary Army, took steps in March to curb the Communists and to send away several Soviet officers whom he believed were scheming with Wang Ching-wei against him. In a readjustment of party affairs, Communists no longer were permitted to hold high offices in the central headquarters, and Wang Ching-wei went into retirement in France. Chiang also demanded Comintern support of a northern military campaign and the return of Gen. V.K. Blücher as his chief military adviser. Blücher, who used the pseudonym Galen in China, was a commander in the Red Army who had worked with Chiang in 1924 and 1925 in developing the Whampoa Military Academy and forming the National Revolutionary Army. Blücher returned to Canton in May and helped refine plans for the Northern Expedition, which began officially in July, with Chiang as commander in chief.

The Northern Expedition. In the Northern Expedition the outnumbered southern forces were infused with revolutionary spirit and fought with great élan. They were assisted by propaganda corps, which subverted enemy troops and agitated among the populace in the enemy's rear. Soviet military advisers accompanied most of the divisions, and Soviet pilots reconnoitred the enemy positions. The army was well financed at the initial stages because of

fiscal reforms in Kwangtung during the previous year, and many enemy divisions and brigades were bought over. Within two months the National Revolutionary Army gained control of Hunan and Hupeh, and by the end of the year it had taken Kiangsi and Fukien. The Nationalist government moved its central headquarters from Canton to the Wu-han cities of the Yangtze. By early spring of 1927, revolutionary forces were poised to attack Nanking and Shanghai.

The political situation, however, was unstable. Hunan and Hupeh were swept by a peasant revolt marked by violence against landlords and other rural power holders. Business in the industrial and commercial centre of the middle Yangtze, the Wu-han cities, was nearly paralyzed by a wave of strikes. Communists and KMT leftists led this social revolution. In January the British concessions in Han-k'ou and Chiu-chiang were seized by Chinese crowds. The British government had just adopted a conciliatory policy toward China, and it acquiesced in these seizures, but it was readying an expeditionary force to protect its more important position in Shanghai. Foreigners and many upper-class Chinese fled from the provinces under Nationalist control. The northern armies began to form an alliance against the Southerners.

The split in the KMT

Conservative Nationalist leaders in Shanghai mobilized against the headquarters in Wu-han. There was a deep rift within the revolutionary camp itself; the leftists at Wu-han, guided by Borodin, pitted themselves against Chiang and his more conservative military supporters, who were also laying plans against the leftists. Resolutions of the CCP's Central Committee in January 1927, showed apprehension of a counterrevolutionary tide against their party, Soviet Russia, and the revolutionary peasant and workers' movement; they feared a coalition within the KMT and its possible alliance with the imperialist powers. The central leadership resolved to check revolutionary excesses and give all support to the KMT leadership at Wu-han. Others within the CCP, notably Mao Zedong, disagreed; they believed the mass revolution should be encouraged to run its course.

Expulsion of Communists from the KMT. The climax of the conflict came after Nationalist armies had taken Shanghai and Nanking in March. Nanking was captured on March 23, and the following morning Nationalist troops looted foreign properties, attacked the British, U.S., and Japanese consulates, and killed seven foreigners. In Shanghai a general strike led by Communists aroused fears that Chinese might seize the International Settlement and French concession, now guarded by a large international expeditionary force. Conservative Nationalist leaders, some army commanders, and Chinese business leaders in Shanghai encouraged Chiang to expel the Communists and suppress the Shanghai General Labour Union. On April 12–13, gangsters and troops bloodily suppressed the guards of the General Labour Union, arrested many Communists, and executed large numbers. Similar suppressions were carried out in Canton, Nanking, Nan-ch'ang, Fuchou, and other cities under military forces that accepted Chiang's instructions. The KMT conservatives then established a rival Nationalist government in Nanking.

Wang Ching-wei had returned to China via the Soviet Union. Arriving in Shanghai, he refused to participate in the expulsions and went secretly to Wu-han, where he again headed the government. In July, however, the leftist Nationalist leaders in Wu-han, having learned of a directive by Joseph Stalin to Borodin to arrange for radicals to capture control of the government, decided to expel the Communists and invite the Soviet advisers to leave. The leftist government thereby lost important bases of support; furthermore, it was ringed by hostile forces and cut off from access to the seas, and it soon disintegrated.

The CCP went into revolt. Using its influence in the Cantonese army of Chang Fa-k'uei, it staged an uprising at Nan-ch'ang on August 1 and then attempted an "Autumn Harvest" uprising in several central provinces. Both efforts failed. In December Communist leaders in Canton started a revolt known as the Canton Commune. They captured the city with much bloodshed, arson, and looting; but this uprising was quickly suppressed, also with much slaughter. Between April and December 1927 the CCP lost most of its membership by death and defection. A few score leaders and some scattered military bands then began the process of creating military bases in the mountains and plains of central China, remote from centres of Nationalist power.

The now more conservative KMT resumed its Northern Expedition in the spring of 1928 with a reorganized National Revolutionary Army. In the drive on Peking it was joined by the National People's Army under Feng Yü-hsiang, part of the Kwangsi army, and the Shansi army of Yen Hsi-shan. In early June they captured Peking, from which Chang Tso-lin and the Fengtien army withdrew for Manchuria. As his train neared Mukden (modern Shenyang), Chang died in an explosion arranged by a few Japanese officers without knowledge of the Japanese government. Japan did not permit the Nationalist armies to pursue the Fengtien army into Manchuria, hoping to keep that area out of KMT control. By the end of the Northern Expedition the major warlords had been defeated by the Nationalists, whose armies now possessed the cities and railways of eastern China. On October 10 the Nationalists formally established a reorganized National Government of the Republic of China, with its capital at Nanking.

Nationalist control of eastern China

The National Government from 1928 to 1937. The most serious immediate problem facing the new government was the continuance of military separatism. The government had no authority over the vast area of western China, and even regions in eastern China were under the rule of independent regimes that had lately been part of the Nationalist coalition. After an unsuccessful attempt at negotiations, Chiang launched a series of civil wars against his former allies. By 1930 one militarist regime after another had been reduced to provincial proportions, and Nanking's influence was spreading. Explained in material terms, Chiang owed his success to the great financial resources of his base in Kiangsu and Chekiang and to foreign arms. Quick recognition by the foreign powers brought the National Government the revenues collected by the efficient Maritime Customs Service; when the powers granted China the right to fix its own tariff schedules, that revenue increased.

Although the aim of constitutional, representative government was asserted, the National Government at Nanking was in practice personally dominated by Chiang Kai-shek. The army and the civil bureaucracy were marked by factional divisions, which Chiang carefully balanced against one another so that ultimate decision making was kept in his own hands. The KMT was supposed to infuse all government structures and to provide leadership, but the army came to be the most powerful component of government. Chiang's regime was marked by a military orientation, which external circumstances reinforced.

Nevertheless, the Nationalists did much to create a modern government and a coherent monetary and banking system and to improve taxation. They expanded the public educational system, developed a network of transportation and communication facilities, and encouraged industry and commerce. Again it was urban China that mainly benefited; little was done to modernize agriculture or to eradicate disease, illiteracy, and underemployment in the villages, hamlets, and small towns scattered over a continental territory. With conscription and heavy taxation to support civil war, and a collapsing export market for commercial crops, rural economic conditions may have grown worse during the Nationalist decade.

The National Government during its first few years in power had some success in reasserting China's sovereignty. Several concession areas were returned to Chinese control, and the foreign powers assented to China's resumption of tariff autonomy. Yet these were merely token gains; the unequal treaties were scarcely breached. The country was in a nationalistic mood, determined to roll back foreign economic and political penetration. Manchuria was a huge and rich area of China in which Japan had extensive economic privileges, possessing part of the Liaotung Peninsula as a leasehold and controlling much of southern Manchuria's economy through the South Manchurian Railway. The Chinese began to develop Hu-lu-tao, in Liaotung, as a port to rival Dairen (modern Lü-ta) and

to plan railways to compete with Japanese lines. Chang Hsüeh-liang, Chang Tso-lin's son and successor as ruler of Manchuria, was drawing closer to Nanking and sympathized with the Nationalists' desire to rid China of foreign privilege.

Japanese interest in Manchuria

For Japan, Manchuria was regarded as vital. Many Japanese had acquired a sense of mission that Japan should lead Asia against the West. The Great Depression had hurt Japanese business, and there was deep social unrest. Such factors influenced many army officers to regard Manchuria as the area where Japan's power must be consolidated, especially officers of the Kwantung Army, which protected Japan's leasehold in the Liaotung Peninsula and the South Manchurian Railway.

Japanese aggression. In September 1931 a group of officers in the Kwantung Army set in motion a plot to compel the Japanese government to extend its power in Manchuria. The Japanese government was drawn, step by step, into the conquest of Manchuria and the creation of a regime known as Manchukuo. China was unable to prevent Japan from seizing this vital area. In 1934, after long negotiations, Japan acquired the Soviet interest in the Chinese Eastern Railway, thus eliminating the last legal trace of the Soviet sphere of influence there. During 1932–35 Japan seized more territory bordering on Manchuria. In 1935 it attempted to detach Hopeh and Chahar from Nanking's control and threatened Shansi, Suiyüan, and Shantung. The National Government's policy was to trade space for time in which to build military power and unify the country. Its slogan "Unity before resistance" was directed principally against the Chinese Communists.

War between Nationalists and Communists. In the meantime, the Communists had created 15 rural bases in central China, and they established a soviet government, the Kiangsi Soviet, on Nov. 7, 1931. Within the soviet regions the Communist leadership expropriated and redistributed land and in other ways enlisted the support of the poorer classes. The Japanese occupation of Manchuria and an ancillary localized war around Shanghai in 1932 distracted the Nationalists and gave the Communists a brief opportunity to expand and consolidate. But the Nationalists in late 1934 forced the Red armies to abandon their bases and retreat. Most of the later Communist leaders, including Mao Zedong, Zhu De (Chu Teh), Zhou Enlai, Liu Shaoqi (Liu Shao-ch'i), and Lin Biao (Lin Piao), marched and fought their way across western China. By mid-1936 the remnants of several Red armies had gathered in an impoverished area in northern Shensi, with headquarters located in the town of Yen-an, which lent its name to the subsequent period (1936–45) of CCP development.

The Long March

During the Long March Mao Zedong rose to preeminence in the CCP leadership. In the early 1930s he had engaged in bitter power struggles with other party leaders and actually had found himself in a fairly weak position at the start of the Long March campaigns; but in January 1935 a rump session of the CCP Political Bureau (Politburo) confirmed Mao in the newly created post of chairman. It was also during the Long March that the CCP began to develop a new political strategy—a united front against Japan. It was first conceived as an alliance of patriotic forces against Japan and the National Government; but as Japan's pressure on China and the pressure of the Nationalist armies against the weakened Red armies increased, the Communist leaders began to call for a united front of all Chinese against Japan alone. Virtually all classes and various local regimes supported this, and the Communists moderated their revolutionary program and terminated class warfare in their zone of control.

Chiang was determined, however, to press on with his extermination campaign. He ordered the Manchurian army under Chang Hsüeh-liang, now based in Sian, and the Northwestern army under Yang Hu-ch'eng to attack the Communist forces in northern Shensi. Many officers in these armies sympathized with the Communist slogan "Chinese don't fight Chinese"; they preferred to fight Japan, a sentiment particularly strong in the homeless Manchurian army. Chang Hsüeh-liang was conducting secret negotiations with the Communists and had suspended the civil war. In December 1936 Chiang Kai-shek flew to Sian to order Chang and Yang to renew the anti-Communist campaign. Under pressure from subordinates, Chang detained Chiang on the morning of December 12 (this became known as the Sian Incident).

The Sian Incident

The United Front against Japan. Fearing that, if Chiang were killed, China would be plunged into renewed disorder, the nation clamoured for his release. The Soviet Union quickly denounced the captors and insisted that Chiang be freed (the Soviet Union needed a united China opposing Japan, its potential enemy on the east). The CCP leaders also decided that Chiang's release would serve China's interests as well as their own, if he would accept their policy against Japan. Zhou Enlai and several other Communist leaders flew to Sian to try to effect this. Chang Hsüeh-liang finally agreed to free his captive, with the understanding that Chiang would call off the civil war and unite the country against the invader. On December 25 Chiang was freed.

The two Chinese parties began protracted and secret negotiations for cooperation, each making concessions. But it was not until September 1937, after the Sino-Japanese War had begun, that the National Government formally agreed to a policy of cooperation with the CCP. For its part, the CCP publicly affirmed its adherence to the realization of Sun Yat-sen's Three Principles of the People, its abandonment of armed opposition to the KMT and of the forcible confiscation of landlords' property, the substitution of democracy for its soviet government, and the reorganization of the Red Army as a component of the national army under the central government.

THE WAR AGAINST JAPAN (1937–45)

The Sino-Japanese War. On July 7, 1937, a minor clash between Japanese and Chinese troops near Pei-p'ing (Peking's name under the National Government) finally led the two nations into war. The Japanese government tried for several weeks to settle the incident locally, but China's mood was highly nationalistic and public opinion clamoured for resistance to further aggression. In late July, new fighting broke out. The Japanese quickly took Pei-p'ing and captured Tientsin. On August 13 savage fighting broke out in Shanghai. By now the prestige of both nations was committed, and they were locked in a war.

Phase one. As never before in modern times, the Chinese united themselves against a foreign enemy. China's standing armies in 1937 numbered some 1,700,000 men, with 500,000 in reserve. Japan's naval and air superiority were unquestioned. But Japan could not commit its full strength to campaigns in China; the main concern of the Japanese Army was the Soviet Union, while for the Japanese Navy it was the United States.

Early Japanese victories

During the first year of the undeclared war, Japan won victory after victory against sometimes stubborn Chinese resistance. By late December, Shanghai and Nanking had fallen. But China had demonstrated to the world its determination to resist the invader; this gave the government time to search for foreign support. China found its major initial help from the Soviet Union. On Aug. 21, 1937, the Soviet Union and China signed a nonaggression pact, and the former quickly began sending munitions, military advisers, and hundreds of aircraft with Soviet pilots. Japanese forces continued to win important victories. By mid-1938 Japanese armies controlled the railway lines and major cities of northern China. They took Canton on October 12, stopping the railway supply line to Wu-han, the temporary Chinese capital, and captured Han-k'ou, Hanyang, and Wu-ch'ang on October 25–26. The Chinese government and military command moved to Chungking in Szechwan, farther up the Yangtze and behind a protective mountain screen.

At the end of this first phase of the war, the National Government had lost the best of its modern armies, its air force and arsenals, most of China's modern industries and railways, its major tax resources, and all the ports through which military equipment and civilian supplies might be imported. But it still held a vast though backward territory and had unlimited manpower reserves. So long as China continued to resist, Japan's control over the conquered eastern part of the country would be difficult.

Phase two: stalemate and stagnation. During the second stage of the war (1939–43) the battle lines changed very little, although there were many engagements of limited scale. Japan tried to bomb Free China into submission; Chungking suffered repeated air raids in which thousands of civilians were killed. In 1940 Japan set up a rival government in Nanking under Wang Ching-wei. But the Chinese would not submit. Hundreds of thousands migrated to west China to continue the struggle. Students and faculties of most eastern colleges took the overland trek to makeshift quarters in distant inland towns. Factories and skilled workers were reestablished in the west. The government rebuilt its shattered armies and tried to purchase supplies from abroad.

Allied aid to China

In 1938–40 the Soviet Union extended credits for military aid of $250,000,000, while the United States, Great Britain, and France granted some $263,500,000 for civilian purchases and currency stabilization. Free China's lines of supply were long and precarious; when war broke out in Europe, shipping space became scarce. After Germany's conquest of France in the spring of 1940, Britain bowed to Japanese demands and temporarily closed Rangoon to military supplies for China (July–September). In September 1940 Japan seized control of northern Indochina and closed the supply line to K'un-ming. The Soviet Union had provided China its most substantial military aid, but when Germany attacked the Soviet Union in June 1941, this aid virtually ceased. By then, however, the United States had sold China 100 fighter planes—the beginning of a U.S. effort to provide air protection.

In addition to bombing, the civilian population in Free China endured great hardships. Manufactured goods were scarce, and hoarding drove up prices. The government did not have the means to carry out rationing and price control, though it did supply government employees with rice. The government's sources of revenue were limited, yet it supported a large bureaucracy and an army of more than 3,000,000 conscripts. The government resorted to printing currency inadequately backed by reserves. Inflation grew until it was nearly uncontrollable. Between 1939 and 1943 the morale of the bureaucracy and military officers declined. Old abuses of the Chinese political system reasserted themselves—factional politics and corruption, in particular. The protracted war progressively weakened the Nationalist regime.

The war had the opposite effect upon the CCP. The Communist leaders had survived 10 years of civil war and had developed a unity, camaraderie, and powerful sense of mission. They had learned to mobilize the rural population and to wage guerrilla warfare. In 1937 the CCP had about 40,000 members and the poorly equipped Red Army numbered perhaps 100,000. By agreement with the National Government, the Red Army was renamed the Eighth Route Army (later the 18th Group Army); Zhu De and Peng Dehuai (P'eng Te-huai) served as commander and vice commander, and Lin Biao, Ho Lung, and Liu Bocheng (Liu Po-ch'eng) were in charge of its three divisions. The Communist base in the northwest covered parts of three provinces with a backward economy and a population of about 1,500,000. Operating within the general framework of the United Front against Japan, the leaders of the Eighth Route Army adopted a strategy that used their experience in guerrilla warfare. They sent small columns into areas of northern China that the Japanese Army had overrun but lacked the manpower to control; there they incorporated remnant troops and organized the population to supply food, recruits, and sanctuaries for guerrilla units attacking small Japanese garrisons.

Communist guerrilla warfare

Early in the period of united resistance, the government permitted the creation of the New 4th Army from remnants of Communist troops left in Kiangsi and Fukien at the time of the Long March. Commanded by Gen. Ye Ting (Yeh T'ing), with Xiang Ying (Hsiang Ying), a Communist, as chief of staff, this force of 12,000 officers and men operated behind Japanese lines near Shanghai with great success. Its strategy included guerrilla tactics, organizing resistance bases, and recruitment. This army grew to more than 100,000 in 1940; by then it operated in a wide area on both sides of the lower Yangtze.

Thus the CCP revitalized itself. It recruited rural activists and patriotic youths from the cities and systematically strengthened the ranks by continuous indoctrination and by expelling dissident and ineffective party members.

Renewed Communist-Nationalist conflict. There were numerous clashes between Communists and Nationalists as their military forces competed for control of enemy territory and as the Communists tried to expand their political influence in Nationalist territory through propaganda and secret organizing. Though both sides continued the war against Japan, each was fighting for its own ultimate advantage. Bitter anti-Communist sentiment in government circles found its most violent expression in the New 4th Army Incident of January 1941.

New 4th Army Incident

The government had ordered the New 4th Army to move north of the Huang Ho and understood that its commanders had agreed to do so as part of a demarcation of operational areas. But most of the army had moved into northern Kiangsu (south of the Huang) and, together with units of the 18th Group Army, was competing with government troops for control of bases there and in southern Shantung. Ye Ting and Xiang Ying stayed at the army's base south of the Yangtze. Apparently believing that Ye did not intend to move northward, government forces attacked the base on Jan. 6, 1941. The outnumbered Communists were defeated, Ye Ting and some 2,000 others were captured, Xiang Ying was killed, and both sides suffered heavy casualties. Ignoring Chiang's order to dissolve the New 4th Army, the Communist high command named Chen Yi (Ch'en I) as its new commander and Liu Shaoqi as political commissar.

The danger of renewed civil war caused widespread protest from China's civilian leaders. The People's Political Council, a multiparty advisory body formed in 1938 as an expression of united resistance, debated the issue and later tried to mediate. Neither the KMT nor the CCP was willing to push the conflict to open civil war in 1941. The government deployed many of its best divisions in positions to prevent the Communist forces from further penetration of Nationalist-held territories and to weaken the CCP through a strict economic blockade.

The international alliance against Japan. The United States had broken the Japanese diplomatic code, and by July 1941 it knew that Japan hoped to end the undeclared war in China and was preparing for a southward advance toward British Malaya and the Dutch East Indies, planning first to occupy southern Indochina and Thailand even at the risk of war with Britain and the United States.

U.S. aid to China. One U.S. response was the decision to send large amounts of arms and equipment to China, along with a military mission to advise on their use. The underlying strategy was to revitalize China's war effort as a deterrent to Japanese military and naval operations southward. The Nationalist army was ill equipped to fight the Japanese in 1941. Its arsenals were so lacking in nonferrous metals and explosives that they could not produce effectively. The maintenance of millions of ill-trained and underequipped troops was a heavy drain on the economy. There was no possibility that the United States could arm such numbers from its limited stocks while building up its own forces and assisting many other nations. And there was a formidable logistics problem in shipping supplies along the 715-mile (1,150-kilometre) Burma Road, which extended from K'un-ming to Lashio, the Burma terminus of the railway and highway leading to Rangoon.

The U.S. military mission

By December 1941 the United States had sent a military mission to China and had implicitly agreed to create a modern Chinese air force, to maintain an efficient line of communications into China, and to arm 30 divisions. Japan's bombing of Pearl Harbor brought the United States into alliance with China, and Great Britain joined the Pacific war as its colonial possessions were attacked. This widening of the Sino-Japanese conflict lifted Chinese morale, but its other early effects were harmful. With the Japanese conquest of Hong Kong on December 25, China lost its air link with the outside world and one of its principal routes for smuggling supplies. By the end of May 1942 the Japanese held most of Burma, having defeated the British, Indian, Burmese, and Chinese

defenders. China was almost completely blockaded. The United States granted China a loan of $500,000,000, and Great Britain stated its willingness to lend £50,000,000, but there was little else China's allies could do.

The solution was found in an air route from Assam, India, to K'un-ming in southwest China—the dangerous "Hump" route along the southern edge of the Himalayas. In March 1942 the China National Aviation Corporation (CNAC) began freight service over the Hump, and the United States began a transport program the next month. But shortages and other difficulties had to be overcome, and not until December 1943 were cargo planes able to equal the tonnage carried along the Burma Road by trucks two years before. This was much less than China's needs for gasoline and military equipment and supplies.

Conflicts within the international alliance. China's alliance with the United States and Great Britain was marked by deep conflict. Great Britain gave highest priority to the defeat of its main enemy, Germany. The U.S. Navy in the Pacific had been seriously weakened by the Japanese air attack at Pearl Harbor and required many months to rebuild. During the winter of 1941–42 the grand strategy of the United States and Great Britain called for the defeat of Germany first and then an assault across the Pacific against Japan's island empire. China was relegated to a low position in U.S. strategic planning. The United States aimed to keep China in the war and enable it to play a positive role in the final defeat of Japan on the continent. Chiang Kai-shek, on the other hand, envisaged a joint strategy by the United States, the British Commonwealth, and China over the whole Pacific area, with China playing a major role. He demanded an equal voice in Allied war planning, which he never received, although U.S. Pres. Franklin D. Roosevelt was generally solicitous. From the fundamentally different outlooks of President Chiang, British Prime Minister Winston Churchill, and President Roosevelt and because of the divergent national interests of China, the British Commonwealth, and the United States, there followed many controversies that had powerful repercussions in China and led to frustrations and suspicions among the partners.

After the fall of Burma, a controversy developed over whether the principal Chinese and U.S. effort against Japan should be devoted to building up U.S. air power based in China or to reform of the Chinese army and its training and equipment for a combat role. Chiang advocated primary reliance on U.S. air power to defeat Japan. Several high-ranking U.S. generals, on the other hand, emphasized creation of a compact and modernized Chinese ground force able to protect the airfields in China and to assist in opening an overland supply route across northern Burma. Already in India, the United States was training two Chinese divisions from remnants of the Burma campaign, plus artillery and engineering regiments (this became known as X-Force). Also in training were Chinese instructors to help retrain other divisions in China. Both air development and army modernizing were being pushed in early 1943, with a training centre created near K'un-ming to reenergize and reequip select Chinese divisions (called Y-Force), and a network of airfields was being built in southern China. This dual approach caused repeated conflict over the allocation of scarce airlift space.

Chinese-U.S. disagreement

By the end of 1943 the China-based U.S. 14th Air Force had achieved tactical parity with the Japanese over central China, was beginning to bomb Yangtze shipping, and had conducted a successful raid on Japanese airfields on Taiwan. A second training centre had been started at Kuei-lin to improve 30 more Chinese divisions (Z-Force). The campaign to open a land route across northern Burma had run into serious difficulty. At the Cairo Conference in November, Chiang met Churchill and Roosevelt for the first time. The Cairo Declaration promised the return of Manchuria, Taiwan, and the Pescadores Islands to China and the liberation of Korea. The three allies pledged themselves to "persevere in the . . . prolonged operations necessary to procure the unconditional surrender of Japan." These words, however, concealed deep differences over global strategy. U.S. planners realized that Japan might be approached successfully through the south and central Pacific and that the Soviet Union would enter the war against Japan after Germany's defeat; hence, the importance of China to U.S. grand strategy declined. Churchill was unwilling to use naval resources, needed for the forthcoming European invasion, in a seaborne invasion of Burma to help reopen China's supply line. Yet Chiang had demanded a naval invasion of Burma as a condition to committing the Y-Force to assist in opening his supply line. Shortly after Cairo, Churchill and Roosevelt agreed to set aside the seaborne invasion of Burma, and when Chiang learned of this he requested enormous amounts of money, supplies, and air support, asserting that otherwise Japan might succeed in eliminating China from the war. The United States did not accede, and Chinese–American relations began to cool.

Phase three: approaching crisis (1944–45). China was in crisis in 1944. Japan faced increasing pressure in the Pacific and threats to its supply bases and communications lines in China as well as to nearby shipping Its response was twofold—first, to attack from Burma toward Assam to cut the supply lines or capture the airfields at the western end of the Hump, and, second, to capture the railway system in China from north to south and seize the eastern China airfields used by the United States.

The British and Indian army defeated the Japanese attack on Assam (March–July 1944) with help from transport planes withdrawn from the Hump. But the Japanese campaign in China, known as Ichigo, showed up the weakness, inefficiency, and poor command of the Chinese armies after nearly seven years of war. During April and May the Japanese cleared the Pei-p'ing–Han-k'ou railway between the Huang and the Yangtze rivers. Chinese armies nominally numbering several hundred thousand men were unable to put up effective resistance. Peasants in Honan attacked the collapsing Chinese armies, their recent oppressors.

Chinese military weaknesses

The second phase of the Ichigo campaign was a Japanese drive southward from Han-k'ou and northwestward from Canton to take Kuei-lin and open the communication line to the India–China border. By November the Chinese had lost Kuei-lin, Liu-chou, and Nan-ning, and the Japanese were approaching Kuei-yang on the route to Chungking and K'un-ming. This was the high watermark of Japan's war in China. Thereafter, it withdrew experienced divisions for the defense of its overextended empire, and China finally began to benefit from the well-trained X-Force when two divisions were flown in from Burma in December to defend K'un-ming.

Meanwhile, the Chinese government was involved in a crisis of relations with the United States, which contended that the Chinese Army must be reformed, particularly in its command structure, and that lend-lease supplies must be used more effectively. There were also many subsidiary problems. Gen. Joseph Stilwell, the executor of disagreeable U.S. policies in China, had developed an unconcealed disdain for Chiang, whom he nominally served as chief of staff. Stilwell was an effective troop commander, and Roosevelt requested that Chiang place Stilwell in command of all Chinese forces. In the context of Chinese politics, in which control of armies was the main source of power, President Chiang's compliance was virtually inconceivable. He declined the request and asked for Stilwell's recall. Roosevelt agreed, but thereafter his relations with Chiang were no longer cordial. Stilwell was replaced by Gen. Albert C. Wedemeyer.

Nationalist deterioration. The military weakness in 1944 was symptomatic of a gradual deterioration that had taken place in most aspects of Nationalist Chinese public life. Inflation began to mount alarmingly as the government pumped in large amounts of paper currency to make up its fiscal deficits. Salaries of government employees, army officers, teachers, and all those on wages fell far behind rising prices. For most, this spelled poverty amid growing war-weariness. Dissatisfaction with the government's policies spread among intellectuals. Inflation gave opportunities for some groups to profit through hoarding of needed goods, smuggling of high-value commodities, black market currency operations, and graft. Corruption spread in the bureaucracy and the armed forces. As the war dragged on,

governmental suppression of dissidence grew oppressive. Secret police activity and efforts at thought control were aimed not only against Communists but also against all influential critics of the government or the KMT.

Communist growth. The Communist armies were growing rapidly in 1943 and 1944. According to U.S. war correspondents visiting the Yen-an area in May 1944 and to a group of U.S. observers that established itself there in July, the Communists professed allegiance to democracy and to continued cooperation with the National Government in the war effort. There was convincing evidence that the areas under Communist control extended for hundreds of miles behind Japanese lines in northern and central China.

Communist economic policy

This situation was the result of many factors. Communist troop commanders and political officers in areas behind Japanese lines tried to mobilize the entire population against the enemy. Party members led village communities into greater participation in local government than had been the case before. They also organized and controlled peasants' associations, labour unions, youth leagues, and women's associations. They linked together the many local governments and the mass organizations and determined their policies. Because of the need for unity against Japan, the Communist organizers tended to follow reformist economic policies. The party experimented with various forms of economic cooperation to increase production; one of these was mutual-aid teams in which farmers temporarily pooled their tools and draft animals and worked the land collectively. In areas behind Japanese lines some mutual-aid teams evolved into work-and-battle teams composed of younger peasants; when danger threatened, the teams went out to fight as guerrillas under direction of the local Red army, and when the crisis passed they returned to the fields. The party recruited into its ranks the younger leaders who emerged from populist activities. Thus, it penetrated and to some extent controlled the multitude of villages in areas behind Japanese lines. As the Japanese military grip weakened, the experienced Communist armies and political organizers spread their system of government ever more widely. By the time of the CCP's Seventh Congress in Yen-an (April–May 1945), the party claimed to have an army of more than 900,000 and a militia of more than 2,000,000. It also claimed to control areas with a total population of 90,000,000. These claims were disputable, but the great strength and wide geographical spread of Communist organization was a fact.

Efforts to prevent civil war. Between May and September 1944, representatives of the government and the CCP carried on peace negotiations at Sian. The main issues were the disposition, size, and command of the Communist armies; the relationship between Communist-organized regional governments and the National Government; and problems of civil rights and legalization of the CCP and its activities in Nationalist areas. Suggestions for a coalition government arose for the first time. No settlement was reached, but it appeared that the antagonists were seeking a peaceful solution. U.S. Vice Pres. Henry Wallace visited Chungking in June and had several discussions with Chiang, who requested U.S. assistance in improving relations between China and the Soviet Union and in settling the Communist problem.

In September 1944, Patrick J. Hurley arrived as Roosevelt's personal representative. Hurley attempted to mediate, first in discussions in Chungking and then by flying to Yen-an on November 7 for a conference with Mao Zedong. But the positions of the two sides could not be reconciled, and the talks broke off in March 1945. Between June and August, Hurley resumed protracted discussions, both indirect and in conferences with high-level representatives from both sides. Each side distrusted the other; each sought to guarantee its own survival, but the KMT intended to continue its political dominance, while the CCP insisted upon the independence of its armies and regional governments under whatever coalition formula might be worked out.

End of the war

The Pacific war ended on Aug. 14, 1945, and the formal Japanese surrender came on September 2. China rejoiced. Yet the country faced enormously difficult problems of reunification and reconstruction and a future clouded by the dark prospect of civil war.

CIVIL WAR (1945–49)

In a little more than four years after Japan's surrender, the CCP and the People's Liberation Army (PLA) conquered mainland China, and, on Oct. 1, 1949, the People's Republic of China was established, with its capital at Peking. The factors that brought this about were many and complex and subject to widely varying interpretation, but the basic fact was a Communist military triumph growing out of a profound and popularly based revolution. The process may be perceived in three phases: (1) from August 1945 to the end of 1946, the Nationalists and Communists raced to take over Japanese-held territories, built up their forces, and fought many limited engagements while still conducting negotiations for a peaceful settlement; (2) during 1947 and the first half of 1948, after initial Nationalist success, the strategic balance turned in favour of the Communists; (3) the Communists won smashing victories in the latter part of 1948 and 1949.

A race for territory. As soon as Japan's impending surrender was known, the commander of the Communist armies, Gen. Zhu De, ordered his men, on August 11, to move into Japanese-held territory and take over Japanese arms, despite Chiang's order that they stand where they were. The United States aided the Chinese government by flying many divisions from the southwest to occupy the main eastern cities, such as Pei-p'ing, Tientsin, Shanghai, and the prewar capital, Nanking. The U.S. Navy moved Chinese troops from South China to other coastal cities, and landed 53,000 marines at Tientsin and Tsingtao to assist in disarming and repatriating Japanese troops but also to serve as a counterweight to the Soviet army in southern Manchuria. Furthermore, U.S. Gen. Douglas MacArthur ordered all Japanese forces in China proper to surrender their arms only to forces of the National Government. They obeyed and thereby were occasionally engaged against Chinese Communist forces.

U.S. aid to the Nationalists

Immediately after the surrender, the Communists sent political cadres and troops into Manchuria. This had been planned long in advance. Gen. Lin Biao became commander of the forces (the Northeast Democratic Allied Army), which incorporated "puppet" troops of Manchukuo and began to recruit volunteers; it got most of its arms from Japanese stocks taken over by the Soviets.

Manchuria was a vast area, with a population of 40,000,000, the greatest concentration of heavy industry and railways in China, and enormous reserves of coal, iron, and many other minerals. The Soviet Union had promised the National Government to withdraw its occupying armies within 90 days of Japan's surrender and to return the region to China. The government was determined to control Manchuria, which was vital to China's future as a world power. But Lin Biao's army attempted to block the entry of Nationalist troops by destroying rail lines and seizing areas around ports of entry. Soon the two sides were locked in a fierce struggle for the corridors into Manchuria, although negotiations were under way in Chungking between Mao and Chiang for a peaceful settlement. The Soviet army avoided direct involvement in the struggle, but it dismantled much industrial machinery and shipped it to the Soviet Union together with hundreds of thousands of Japanese prisoners of war. By the end of 1945 the Nationalists had positioned some of their best U.S.-trained armies in southern Manchuria as far north as Mukden (modern Shen-yang), a strategic rail centre to which Nationalist troops were transported by air. The government's hold was precarious, however, because the Communist 18th Group Army and the New 4th Army had regrouped in North China, abandoning areas south of the Yangtze after a weak bid to take Shanghai. By the end of 1945 Communist forces were spread across a band of provinces from the northwest to the sea. They had a grip on great sections of all the railway lines north of the Lung-hai, vital supply lines for Nationalist armies in the Tientsin–Pei-p'ing area and in Manchuria. The National Government held vast territories in the South and west and had reestablished its authority in the rich provinces

The struggle for Manchuria

of the lower Yangtze Valley and a few important North China cities; it had also assumed civil control on Taiwan.

Attempts to end the war. Peace negotiations continued in Chungking between Nationalist and Communist officials after Japan's surrender. An agreement reached on Oct. 10, 1945, called for the convening of a multiparty Political Consultative Council to plan a liberalized postwar government and to draft a constitution for submission to a national congress. Still, the sides were far apart over the character of the new government, control over the Communist liberated areas, and the size and degree of autonomy of the Communist armies in a national military system. Hurley resigned his ambassadorship on November 26, and the next day U.S. Pres. Harry S. Truman appointed Gen. George C. Marshall as his special representative, with the specific mission of trying to bring about political unification and the cessation of hostilities in China.

Marshall arrived in China on December 23. The National Government proposed the formation of a committee of three, with Marshall as chairman, to end the fighting. This committee, with generals Chang Chun and Zhou Enlai as the Nationalist and Communist representatives, met on Jan. 7, 1946. It agreed on January 10 that Chiang and Mao would issue orders to cease hostilities and halt troop movements as of January 13 midnight, with the exception of government troop movements south of the Yangtze and into and within Manchuria to restore Chinese sovereignty. The agreement also called for the establishment in Pei-p'ing of an executive headquarters, equally represented by both sides, to supervise the cease-fire.

Cease-fire agreement

This agreement provided a favourable atmosphere for meetings in Chungking of the Political Consultative Council, composed of representatives of the KMT, the CCP, the Democratic League, the Young China Party, and nonparty delegates. From Jan. 10 to 31, 1946, the Council issued a series of agreed recommendations regarding governmental reorganization, peaceful national reconstruction, military reductions, a national assembly, and the drafting of a constitution. President Chiang pledged that the government would carry out these recommendations, and the political parties stated their intention to abide by them. The next step was meetings of a military subcommittee, with Marshall as adviser, to discuss troop reductions and amalgamation of forces into a single national army.

Early 1946 was the high point of conciliation. It soon became clear, however, that implementation of the various recommendations and agreements was being opposed by conservatives in the KMT, who feared the dilution of their party's control of the government, and by Nationalist generals, who objected to the reduction of their armies. The Communists attempted to prevent the extension of Nationalist military control in Manchuria. On March 17–18 a Communist army attacked and captured a strategic junction between Mukden and Ch'ang-ch'un, the former Manchukuo capital; on April 18, Communists captured Ch'ang-ch'un from a small Nationalist garrison directly after the Soviet withdrawal. On that day Marshall returned to China after a trip to Washington and resumed his efforts to stop the spreading civil war.

Resumption of fighting. Each side seemed convinced that it could win by war what it could not achieve by negotiation—dominance over the other. Despite the efforts of Chinese moderates and General Marshall, fighting resumed in July in Manchuria, and in North China the Nationalists attempted massive drives in Kiangsu and Shantung to break the Communist grip on the railways. The Communists launched a propaganda campaign against the United States, playing upon the nationalistic theme of liberation; they were hostile because of the extensive U.S. military and financial assistance to the KMT at the very time that Marshall was mediating. The National Government had become increasingly intransigent, confident of continued U.S. help. To exert pressure and to try to keep the United States out of the civil war, Marshall in August imposed an embargo on further shipment of U.S. arms to China. By the end of the year, however, he realized that his efforts had failed. In January 1947 he left China, issuing a statement denouncing the intransigents on both sides. All negotiations ended in March; the die was cast for war.

In the latter half of 1946, government forces made impressive gains in North China and Manchuria, capturing 165 towns from the enemy. Buoyed by these victories, the government convened a multiparty National Assembly on November 15, despite a boycott by the CCP and the Democratic League. The delegates adopted a new constitution, which was promulgated on New Year's Day. The constitution reaffirmed Sun Yat-sen's Three Principles of the People as the basic philosophy of the state; called for the fivefold division of powers among the executive, legislative, judicial, control, and examination *yüan* ("governmental bodies"); and established the four people's rights of initiation, referendum, election, and recall. The way was prepared for election of both central and local officials, upon which the period of Nationalist tutelage would end.

The National Government struggled with grave economic problems. Inflation continued unabated, caused principally by government financing of military and other operations through the printing press: approximately 65 percent of the budget was met by currency expansion and only 10 percent by taxes. Government spending was uncontrolled; funds were dissipated in maintaining large and unproductive garrison forces. Much tax revenue failed to reach the treasury because of malpractices throughout the bureaucracy. Inflation inhibited exports and enhanced the demand for imports. The government had to import large amounts of grain and cotton, but in the months immediately after Japan's surrender it also permitted the import of luxury goods without effective restrictions. As an anti-inflationary measure, it sold gold on the open market. These policies permitted a large gold and U.S. currency reserve, estimated at $900,000,000 at the end of the war, to be cut in half by the end of 1946. Foreign trade was hampered by excessive regulation and corrupt practices.

Economic problems of the National Government

The spiraling effects of inflation were somewhat curbed by large amounts of supplies imported by the United Nations Relief and Rehabilitation Administration, chiefly food and clothing, a wide variety of capital goods, and materials for the rehabilitation of agriculture, industry, and transportation. In August 1946 the United States sold to China civilian-type army and navy surplus property at less than 20 percent of the estimated procurement cost of $900,000,000. In spite of these and other forms of aid, the costs of civil war kept the budget continuously out of balance. Speculation, hoarding of goods, and black market operations as hedges against inflation continued unabated. The constant depreciation in the value of paper currency undermined morale in all classes dependent upon salaries, including troops, officers, and civilian officials.

By contrast, it appears that in their areas, mostly rural, the Communists practiced a Spartan style of life close to the common people. Morale remained high in the army and was continuously bolstered by indoctrination and effective propaganda. As they had during the war years, Communist troops tried in many ways to win support of the masses. In newly occupied areas social policy was at first reformist rather than revolutionary.

In Manchuria, Lin Biao was forging a formidable army of veteran cadres from North China and natives of Manchuria, now well equipped with Japanese weapons. By 1947 the Communists' Northeast Democratic Allied Army controlled all of Manchuria north of the Sungari River, the east, and much of the countryside in the Nationalist stronghold in the South. There the Nationalists had most of their best trained and equipped divisions; but the troops had been conscripted or recruited in China's southwest, and they garrisoned cities and railways in a distant land. Beginning in January 1947, Lin Biao launched a series of small offensives. By July the Nationalists had lost half of their territory in Manchuria and much matériel; desertions and casualties, caused by indecisive Nationalist leadership and declining troop morale, reduced their forces by half. Lin Biao was not yet strong enough to take Manchuria, but he had the Nationalist armies hemmed up in a few major cities and with only a tenuous hold on the railways leading southward.

Communist gains in Manchuria

The tide begins to shift. Although government forces overran Yen-an in March 1947, the strategic initiative passed to the PLA during that year. In midsummer Liu

Bocheng started moving toward the Yangtze; by late in the year the Communists had concentrated strong forces in central China. Chen Yi operated on both sides of the Lung-hai, east of K'ai-feng; Liu Bocheng was firmly established in the Ta-pieh Shan on the borders of Anhwei, Honan, and Hupeh, northeast of Han-k'ou; and Chen Geng (Ch'en Keng) had another army in Honan west of the Pei-p'ing–Han-k'ou railway. These groups cut Nationalist lines of communication, they destroyed protecting outposts along the Lung-hai and Ping-han lines, and they isolated cities.

By the end of 1947 the government forces, according to U.S. military estimates, still numbered some 2,700,000 facing 1,150,000 Communists. But the Nationalists were widely spread and on the defensive. In November, Mao Zedong established the Communist capital at Shih-chia-chuang, a railway centre leading from the Pei-p'ing–Han-k'ou railway into Shansi; this was a measure of the consolidation of the Communist position in North China. In a report to the CCP Central Committee on Dec. 25, 1947, Mao exuded confidence:

> The Chinese people's revolutionary war has now reached a turning point. . . . The main forces of the People's Liberation Army have carried the fight into the Kuomintang Area. . . . This is a turning point in history.

A land revolution. One reason for Communist success was the social revolution in rural China. The CCP was now unrestrained by the multiclass alliance of the United Front period. In the middle of 1946, as civil war became more certain, the party leaders launched a land revolution. They saw land redistribution as an integral part of the larger struggle; by encouraging peasants to seize the landlords' fields and other property, the party apparently expected to weaken the government's rural class base and strengthen its own support among the poor. This demanded a decisive attack upon the traditional village social structure. The party leaders believed that to crack the age-old peasant fear of the local elite and overcome traditional respect for property rights required unleashing the hatred of the oppressed. Teams of activists moved through the villages, organizing the poor in "speak bitterness" meetings to struggle against landlords and Nationalist supporters, to punish and often to kill them, and to distribute their land and property. The party tried to control the process in order not to alienate the broad middle ranks among the peasants; but land revolution had a dynamism of its own, and rural China went through a period of terror. Yet apparently the party gained from the revolutionary dynamism; morale was at fever pitch, and, for those who had benefited from land distribution, there was no turning back.

The turning point in the war

The decisive year, 1948. The year 1948 was the turning point. In central China, Communist armies of 500,000 men proved their ability to fight major battles on the plains and to capture, though not always hold, such important towns on the Lung-hai as Lo-yang and K'ai-feng. In North China they encircled T'ai-yüan, the capital of Shansi; took most of Chahar and Jehol, provinces on Manchuria's western flank; and recaptured Yen-an, which had been lost in March 1947. The decisive battles were fought in Shantung and Manchuria, where the forces of Chen Yi and Liu Bocheng and those under Lin Biao crushed the government's best armies. For the government it was a year of military and economic disasters.

In Shantung, despite the departure of Chen Yi's forces, Communist guerrillas gradually reduced the government's hold on the railway from Tsingtao to Chi-nan; they penned up about 60,000 government troops in the latter city, an important railway junction. Instead of withdrawing this garrison southward to Suchow, the government left it, for political reasons, to stand and fight. Then Chen Yi's forces returned to Shantung and overwhelmed the dispirited Chi-nan garrison on September 24. This opened the way for a Communist attack upon Suchow, the historic northern shield for Nanking and a vital railway centre.

Beginning in December 1947, a Communist offensive severed all railway connections into Mukden and isolated the Nationalist garrisons in Manchuria. The government armies went on the defensive in besieged cities, partly out of fear that demoralized divisions would defect in the field. Instead of withdrawing from Manchuria before it was too late, the government tried unsuccessfully to reinforce its armies and to supply the garrisons by air. With the fall of Chi-nan, Lin Biao launched his final offensive. He now had an army of 600,000, nearly twice the Nationalist force in Manchuria. He first attacked Chin-chou, the government's supply base on the railway between Chi-nan and Mukden; it fell on October 17. Ch'ang-ch'un fell three days later. The great garrison at Mukden then tried to retake Chin-chou and Ch'ang-ch'un and to open the railway line to the port of Ying-k'ou. In a series of battles, Lin Biao's columns defeated this cream of the Nationalist forces. By early November the Nationalists had lost some 400,000 men as casualties, captives, or defectors.

Lin Biao's final offensive

The government's military operations in the first part of 1948 produced ever larger budget deficits through the loss of tax receipts, dislocation of transportation and productive facilities, and increased military expenditures. Inflation was out of control. In August the government introduced a new currency, the gold yuan, to replace the old notes at the rate of 3,000,000 for one, promising drastic reforms to curtail expenditures and increase revenue. Domestic prices and foreign-exchange rates were pegged, with severe penalties threatened for black market operations. The people were required to sell their gold, silver, and foreign currency to the government at the pegged rate; large numbers did so in a desperate effort to halt the inflation. In Shanghai and some other places the government used Draconian methods to enforce its decrees against speculators, but it apparently could not control its own expenditures or stop the printing presses. Furthermore, the government's efforts to fix prices of food and commodities brought about an almost complete stagnation of economic activity, except for illicit buying and selling at prices far above the fixed levels. Some army officers and government officials were themselves engaged in smuggling, speculation, and other forms of corruption. Then came the loss of Chi-nan and knowledge of the threat in Manchuria. During October the final effort to halt inflation collapsed, with shattering effect to morale in Nationalist-held cities. Prices started rocketing upward once more.

Communist victory. Between early November 1948 and early January 1949, the two sides battled for the control of Suchow. Gen. Zhu De concentrated 600,000 men under Chen Yi, Liu Bocheng, and Chen Geng near that strategic centre, which was defended by Nationalist forces of similar size. Both armies were well equipped, but the Nationalists had a superiority in armour and were unopposed in the air. Yet poor morale, inept command, and a defensive psychology brought another disaster to the National Government. One after another its armies were surrounded and defeated in the field. When the 65-day battle was over on January 10, the Nationalists had lost some 500,000 men and their equipment. The capital at Nanking would soon lie exposed.

With Manchuria and most of the eastern region south to the Yangtze in Communist hands, the fate of Tientsin and Pei-p'ing was sealed. The railway corridor between Tientsin and Chang-chia-k'ou was hopelessly isolated. Tientsin fell on January 15 after a brief siege, and Fu Tso-i surrendered Pei-p'ing on the 23rd, allowing a peaceful turnover of China's historic capital and centre of culture.

Thus, during the last half of 1948, the Communist armies had gained control over Manchuria and northeastern China nearly to the Yangtze, except for pockets of resistance. They had a numerical superiority and had captured such huge stocks of rifles, artillery, and armour that they were better equipped than the Nationalists.

Political shifts in 1949

Great political shifts occurred in 1949. Chiang Kai-shek retired temporarily in January, turning over to the vice president, Gen. Li Tsung-jen, the problem of holding together a government and trying to negotiate a peace with Mao Zedong. But Li's peace negotiations (February–April) proved hopeless. The Nationalists were not prepared to surrender; they still claimed to govern more than half of China and still had a large army. General Li tried to secure U.S. support in the peace negotiations and in the military defense of South China, but the U.S. government,

attempting to extricate itself from its entanglement with the collapsing forces of the National Government, pursued a policy of noninvolvement.

Final Communist victories

When peace negotiations broke down, Communist armies crossed the Yangtze virtually unopposed; the National Government abandoned its undefensible capital on April 23 and moved to Canton. In succession, Communist forces occupied Nanking (April 24), Han-k'ou (May 16–17), and Shanghai (May 25). The Nationalists' last hope lay in the South and west. But Sian, a long-time Nationalist bastion and the gateway to the northwest, had fallen to Gen. Peng Dehuai on May 20. During the last half of 1949 powerful Communist armies succeeded in taking the provinces of south and west China. By the end of the year only the islands of Hai-nan, Taiwan, and a few offshore positions were still in Nationalist hands, and only scattered pockets of resistance remained on the mainland. The defeated National Government reestablished itself on Taiwan, to which Chiang had withdrawn early in the year, taking most of the government's gold reserves and the Nationalist Air Force and Navy. On October 1, with most of the mainland held by the PLA, Mao proclaimed the establishment in Peking of the government of the People's Republic of China. (C.M.Wi./E.P.Y.)

The People's Republic of China

The Communist victory in 1949 brought to power a peasant party that had learned its techniques in the countryside but had adopted Marxist ideology and believed in class struggle and rapid industrial development. Extensive experience in running base areas and waging war before 1949 had given the Chinese Communist Party (CCP) deeply ingrained operational habits and proclivities. The long civil war that created the new nation, however, had been one of peasants triumphing over urban dwellers and had involved the destruction of the old ruling classes. In addition, the party leaders recognized that they had no experience in overseeing the transitions to socialism and industrialism that would occur in China's huge urban centres. For this, they turned to the only government with such experience—the Soviet Union. Western hostility against the People's Republic of China, sharpened by the Korean War, contributed to the intensity of the ensuing Sino-Soviet relationship.

ESTABLISHMENT OF THE PEOPLE'S REPUBLIC

When the CCP proclaimed the People's Republic, most Chinese understood that the new leadership would be preoccupied with industrialization. A priority goal of the Communist political system was to raise China to the status of a great power. While pursuing this goal, the "centre of gravity" of Communist policy shifted from the countryside to the city, but Chairman Mao Zedong (Mao Tse-tung) insisted that the revolutionary vision forged in the rural struggle would continue to guide the party.

In a series of speeches in 1949 Chairman Mao stated that his aim was to create a socialist society and, eventually, world Communism. These objectives, he said, required transforming consumer cities into producer cities to set the basis on which "the people's political power could be consolidated." He advocated forming a four-class coalition of elements of the urban middle class—the petty bourgeoisie and national bourgeoisie—with workers and peasants, under the leadership of the CCP. The people's state would exercise a dictatorship "for the oppression of antagonistic classes" made up of opponents of the regime.

The four-class coalition

The authoritative legal statement of this "people's democratic dictatorship" was given in the 1949 Organic Law for the Chinese People's Political Consultative Conference, and at its first session the conference adopted a Common Program that formally sanctioned the organization of state power under the coalition. Following the Communist victory, a widespread urge to return to normality helped the new leadership restore the economy. Police and party cadres in each locality, backed up by army units, began to crack down on criminal activities associated with economic breakdown. Soon it was possible to speak of longer-term developmental plans.

The cost of restoring order and building up integrated political institutions at all levels throughout the nation proved important in setting China's course for the next two decades. Revolutionary priorities had to be made consonant with other needs. Land reform did proceed in the countryside: landlords were virtually eliminated as a class, land was redistributed, and, after some false starts, China's countryside was placed on the path toward collectivization. In the cities, however, a temporary accommodation was reached with non-Communist elements; many former bureaucrats and capitalists were retained in positions of authority in factories, businesses, schools, and governmental organizations. The leadership recognized that such compromises endangered their aim of perpetuating revolutionary values in an industrializing society, yet out of necessity they accepted the lower priority for Communist revolutionary goals and a higher place for organizational control and enforced public order.

Once in power, Communist cadres could no longer condone what they had once sponsored, and inevitably they adopted a more rigid and bureaucratic attitude toward popular participation in politics. Many Communists, however, considered these changes a betrayal of the revolution; their responses gradually became more intense, and the issue eventually began to divide the once cohesive revolutionary elite. This development is central to an understanding of China's political history since 1949.

Scholars tend to divide China's history into periods after the formation of the People's Republic in 1949. These postwar periods, which will be discussed here briefly, must be used with caution, however, because their definition depends so much on which events are selected for emphasis.

Reconstruction and consolidation, 1949–52. During this period, the CCP made great strides toward bringing the country through three critical transitions: from economic prostration to economic growth, from political disintegration to political strength, and from military rule to civilian rule. The determination and capabilities demonstrated during these first years—and the respectable showing (after a century of military humiliations) that Chinese troops made against UN forces on the Korean Peninsula in 1950–53—provided the CCP with a reservoir of popular support that would be a major political resource for years.

Liberation Army troops—called Chinese People's Volunteers—entered the Korean War against United Nations forces in October 1950. Peking had felt threatened by the northward thrust of UN units and had attempted to halt them by its threats to intervene. These threats were ignored by U.S. Gen. Douglas MacArthur, however, and when UN troops under his command reached the Chinese border, Peking acted. By the war's end in July 1953 approximately two-thirds of China's combat divisions had seen service in Korea.

Intervention in the Korean War

In the three years of war, a "Resist America, Aid Korea" campaign translated the atmosphere of external threat into a spirit of sacrifice and enforced patriotic emergency at home. Regulations for the Suppression of Counterrevolutionaries (Feb. 20, 1951) authorized police action against dissident individuals and suspected groups. A campaign against anti-Communist holdouts, bandits, and political opponents was also pressed. Greatest publicity attended Peking's dispatch of troops to Tibet at about the same time that it intervened in Korea. The distinctiveness and world reputation of the Tibetan culture was to make this a severe test of Communist efforts to complete the consolidation of their power. In 1959, after a period of sporadic clashes with the Chinese, the Tibetans rose in rebellion, to which Peking responded with force.

Under the Agrarian Reform Law (June 1950) the property of rural landlords was confiscated and redistributed, which fulfilled a promise to the peasants and smashed a class identified as feudal or semifeudal. The property of traitors, "bureaucrat capitalists" (especially the "four big families" of the Nationalist Party [KMT]—the K'ungs, Soongs, Chiangs, and Ch'ens), and selected foreign nationals was also confiscated, helping end the power of many industrialists and providing an economic basis for industrialization. Programs were begun to increase production and to lay the basis for long-term socialization.

These programs coincided with a massive effort to win over the population to the leadership. Such acts as a marriage law (May 1950) and a trade-union law (June 1950) symbolized the break with the old society, while mass organizations and the regime's "campaign style" dramatized the new.

During 1949–50, policy toward the cities focused on restoring order, rehabilitating the economy, and—above all—wringing disastrous inflation out of the urban economy. To accomplish these tasks, the CCP tried to discipline the labour force, win over the confidence of the capitalists, and implement drastic fiscal policies so as to undercut inflation. These policies brought such remarkable successes that by late 1950 many urban Chinese viewed the CCP leadership as needed reformers. Indeed, numerous capitalists believed them to be "good for business."

Beginnings of the economic and social revolution

But beginning in 1951, the revolutionary agenda of the Communists began to be felt in the cities. A Suppression of Counterrevolutionaries campaign dealt violently with many former leaders of secret societies, religious associations, and the KMT in early 1951. In late 1951 and early 1952, three major political campaigns brought the revolutionary essence of the CCP home to key urban groups. The Three Antis campaign targeted Communist cadres who had become too close to China's capitalists. The Five Antis campaign aimed at the capitalists themselves and brought them into line on charges of bribery, tax evasion, theft of state property and economic information, and cheating on government contracts. And the Thought Reform campaign humbled university professors and marked a turning point in the move from Western to Soviet influence in structuring China's university curriculum.

The pressures toward national political consolidation and the costly struggle in Korea produced significant consequences. In the several provinces of Manchuria (now called the Northeast) there was a growing concentration of industrial and military presence, as well as an increased presence of Soviet economic advisers and key elements of China's tiny corps of technicians and specialists. This was a natural development in view of the extensive economic infrastructure left behind by the Japanese in this region and its proximity to Korea. Additionally, Northeast China had long been an area of Soviet interest.

Gao Gang (Kao Kang) headed Northeast China, and, in addition to his authoritative regional position, Gao also influenced decisions in Peking. He planned the Three-Anti campaign and took the lead in adapting Soviet techniques to Chinese factory management and economic planning. He promoted these techniques on a national basis when he moved to Peking in late 1952 to set up the State Planning Commission. Working closely with the head of the party's Organization Department and other senior officials, Gao subsequently allegedly tried to reduce drastically the authority of his potential competitors, notably Liu Shaoqi (Liu Shao-ch'i) and Zhou Enlai (Chou En-lai), both leading members of party and state organs. The ensuing power struggle lasted more than a year, reflecting an underlying fissure in the CCP. Gao himself had long been a man of the rural base areas, while Liu and Zhou were associated far more with the pre-1949 work in the "white areas" (areas outside CCP control). After 1949, base area veterans believed that they received fewer high positions than their struggles in the wilderness had warranted. Within weeks after the National Conference of the party (March 1955) had proclaimed the defeat of the Gao clique, Peking approved a long-delayed First Five-Year Plan (technically covering the years 1953–57). That summer, active programs for agricultural collectivization and the socialization of industry and commerce were adopted.

Changes in Soviet influence

The period 1949–52 was marked by changes in Soviet influence in China. The officially sanctioned terms of that influence had been worked out in a visit by Mao to Moscow from mid-December 1949 until the following March and were formalized in a Treaty of Friendship, Alliance, and Mutual Assistance (signed Feb. 14, 1950). Years later the Chinese charged that Moscow had failed to give Peking adequate support under that treaty and had left the Chinese to face UN forces virtually alone in Korea. The seeds of doubt concerning Soviet willingness to help China had been sown. Moreover, one of the errors purportedly committed by Gao Gang was his zealousness in using Soviet advisers and promoting the Soviet economic model for management. After the purge of pro-Gao elements, steps were taken to reduce direct Soviet control in China. These steps included reaching agreement on the final withdrawal of Soviet troops from Port Arthur (Lü-shun) by mid-1955. Moscow proved amenable to these changes, as Stalin's death had produced new Soviet efforts to end tensions with the Chinese. The applicability of the Soviet model to China and the degree to which its use might become a pretext for Soviet manipulation of China began to be questioned.

Nevertheless, these potential reductions in Soviet influence were counterbalanced by growing Soviet activity in other fields. The Chinese army was reorganized along Soviet lines, with a greater emphasis on heavy firepower and mobility. Soviet texts and propaganda materials flooded the country. The Soviet Union had earlier extended $300,000,000 credit (used up by 1953); this was followed by a smaller developmental loan in 1954 (used up by 1956). Under these aid programs the Soviets supplied the equipment and technical aid for a large number of industrial projects. The Soviet Union also played a major role in Chinese foreign policy, and it appears that China accepted Moscow's leadership in the international Communist movement. Coordinating with Stalin, Peking supported revolutionary activity throughout Asia and opposed compromise with neutralist regimes.

Beginning of rapid industrialization

The transition to socialism, 1953–57. The period 1953–57, corresponding to the First Five-Year Plan, began China's rapid industrialization. This period is still regarded as having been enormously successful. A strong central governmental apparatus proved able to channel scarce resources into the rapid development of heavy industry. Despite some serious policy issues and problems, the Communist leadership seemed to have the overall situation well in hand. Public order improved and many saw a stronger China taking form. The march to socialism seemed to go along reasonably well with the dictates of industrial development. The determination and fundamental optimism of the Communist leaders appeared justified, especially in view of the decades of invasion, disintegration, self-doubt, and humiliation that had been the lot of the Chinese people before 1949.

The First Five-Year Plan was explicitly modeled on Soviet experience, and the Soviet Union provided both material aid and extensive technical advice on its planning and execution. During 1952–54 the Chinese established a central planning apparatus and a set of central ministries and other government institutions that were close copies of their Soviet counterparts. These actions were officially ratified by the first meeting of the National People's Congress in September 1954, which formally established the Central People's Government and adopted the first constitution of the People's Republic of China. The plan adopted Stalinist economic priorities. In a country where more than 80 percent of the population lived in rural areas, about 80 percent of all government investment was channeled into the urban economy. The vast majority of this investment went to heavy industry, leaving agriculture relatively starved for resources. The plan provided for substantial income differentials to motivate the labour force in the state sector, and it established a "top down" system in which a highly centralized government apparatus exercised detailed control over economic policy through enormous ministries in Peking. These developments differed substantially from the priorities and proclivities of the Chinese Communist movement in the decades before 1949. Nevertheless, the First Five-Year Plan was linked with the transition of China's rural and urban economy to collective forms.

Rural collectivization. This transition was most obvious in the countryside. After land reform had been carried out, mutual aid teams allowed the Communists to experiment with voluntary forms of agricultural collectivization. Starting in late 1953, a campaign was launched to organize into small collectives, called lower level agricultural producers' cooperatives, averaging 20 to 30 households.

Vehement debate soon broke out within the CCP concerning how quickly to move to higher stages of cooperative production in the countryside. This debate was symptomatic of the larger tensions within the party regarding urban and rural development, Soviet influence, and the development of huge government ministries in Peking. The strengths of Mao Zedong lay in agricultural policy, social change, and foreign relations, and in the mid-1950s he began to shift the national agenda more in the direction of his own expertise.

In July 1955 Mao, against the wishes of most of his colleagues in the CCP leadership, called for an acceleration of the transition to lower-level, and then to higher-level, agricultural producers' cooperatives in the countryside. The key difference between these two forms concerned the middle class of peasants, farmers able to live off their own land. The advanced cooperative was particularly disadvantageous to the wealthier peasants because it invested the cooperative itself with title to the land, granting no right of withdrawal, and because wages were based on labour performed, not land contributed. This also made middle-level peasants resent landless peasants, whom the party was recruiting into the new cooperatives. Also, the advanced form, modeled on the Soviet *kolkhoz,* brought with it the outside political controls that were necessary to extract the agricultural surpluses required to pay for China's capital equipment in its industrialization and to feed the workers moving into the cities to man the growing industries. Many middle-level peasants actively resisted these changes and the measures for enforcing them, particularly grain rationing, compulsory purchase quotas, and stricter regulations on savings and wage rates. Nevertheless, Chinese agricultural organization in 1956 reached the approximate level of collectivization achieved in the Soviet Union—a peasant owned his house, some domestic animals, a garden plot, and his personal savings; by the end of 1956, 88 percent of China's peasant households were organized into advanced cooperatives.

Higher level cooperatives

Urban socialist changes. Mao combined this massive transformation of the agricultural sector with a call for the "socialist transformation" of industry and commerce, in which the government would become, in effect, the major partner. In Chinese Communist fashion, this change was not simply decreed from above. Rather, extreme pressures were put on private merchants and capitalists in late 1955 to "volunteer" their enterprises for transformation into "joint state–private" firms. The results were sometimes extraordinary. For example, all the capitalists in a given trade (such as textiles) would parade together to CCP headquarters to the beat of gongs and the sound of firecrackers. Once there, they would present a petition to the government, asking that the major interest in their firms be bought out at the rate that the government deemed appropriate. The government would graciously agree.

Such actions can be understood against the background of the experiences of the capitalists in the previous few years. The Five-Anti campaign of 1952 had terrorized many of them and had left most of them deeply in debt to the government, owing purported back taxes and financial penalties. In any case, the state sector of the economy and state controls over banking had increased to such a degree that the capitalists relied heavily on the government for the contracts and business necessary to keep from bankruptcy. After the Five-Anti campaign, the government extended the reach of its trade unions into the larger capitalist enterprises, and the "joint labour–management" committees set up under government pressure in those firms usurped much of the power that the capitalists formerly had exercised. Thus, many Chinese capitalists saw the socialist transformation of 1955–56 as an almost welcome development since it secured their position with the government while costing them little in money or power.

Political developments. The socialist transformation of agriculture, industry, and commerce thus went relatively smoothly. Nevertheless, changes of this sort could not take place without considerable tensions. Many peasants streamed into the cities in 1956–57 to escape the new cooperatives and to seek employment in the rapidly expanding state-run factories, where government policy kept wages rising rapidly. China's urban population mushroomed from 77,000,000 in 1953 to 99,500,000 by 1957.

Three major economic problems

Several problems also became increasingly pressing. First, CCP leaders found that the agricultural sector was not growing fast enough to provide additional capital for its own development and to feed the workers of the cities. Until then, agricultural policy had attempted to wring large production increases out of changes in organization and land ownership, with little capital investment. By 1956–57 this policy was shown to be inadequate.

Second, Soviet assistance had been made available to China as loans, not grants. After 1956 China had to repay more each year than it borrowed in new funds. Thus, the Chinese could no longer count on Moscow for net capital accumulation in its industrialization drive.

Third, the vastly expanded governmental responsibility for managing the country's urban firms and commerce required far more experts than before. For this, the leadership tried to resolve the increasingly severe strains that had characterized the relationship between the country's intellectuals (including technical specialists) and the CCP.

The leadership's policies in the past had reflected much ambivalence toward the intelligentsia—on the one hand it had required their services and prestige, but on the other it had suspected that many were untrustworthy, coming from urban and bourgeois backgrounds and often having close family and other personal ties with the KMT. After 1949 and particularly during the first part of the Korean War, the Central Committee launched a major campaign to reeducate teachers and scientists and to discredit Western-oriented scholarship. In 1951 the emphasis shifted from general campaigns to self-reform; in 1955 it shifted once again to an intensive thought-reform movement, following the purge of Hu Feng, until then the party's leading spokesman on art and literature. This latter movement coincided with the denunciation of a scholarly study of the *Dream of the Red Chamber,* an 18th-century novel of tragic love and declining fortunes in a Chinese family. Literature without a clear class moral received blistering criticism, as did any hint that the party should not command art and literature—a theme identified with the ousted Hu Feng—and "Hu Feng elements" were exposed among intellectuals in schools, factories, and cooperatives.

The intensity of these attacks slackened in early 1956. Party leaders publicly discussed the role of intellectuals in the new tasks of national construction and adopted the line of "Let a hundred flowers blossom, a hundred schools of thought contend." Because intellectuals in China included high school graduates as well as those with college or advanced professional training, the policy affected a vast number of people. The "hundred flowers" line explicitly encouraged "free-ranging" discussion and inquiry, with the explicit assumption that this would prove the superiority of Marxism-Leninism and speed the conversion of intellectuals to Communism. Their response was gradual and cautious to the party's invitation for free discussion and criticism. Instead of embracing Marxism, moreover, many used the opportunity to translate and discuss Western works and ideas and blithely debated "reactionary" doctrines at the very moment Hungarian intellectuals were triggering a wave of anti-Communist sentiment in Budapest.

Hundred Flowers Campaign

Following this initial phase of the Hundred Flowers Campaign, Mao Zedong issued what was perhaps his most famous post-1949 speech "On the Correct Handling of Contradictions Among the People" (Feb. 27, 1957). Its essential message was ambiguous. He stressed the importance of resolving "nonantagonistic contradictions" by methods of persuasion, but he stated that "democratic" methods of resolution would have to be consistent with centralism and discipline. He left it unclear when a contradiction might become an "antagonistic" and no-holds-barred struggle. The final authoritative version of this speech contained explicit limits on the conduct of debate that had been absent in the original. According to this version, the party would judge words and actions to be correct only if they united the populace, were beneficial to socialism, strengthened the state dictatorship, consolidated organizations, especially the party, and generally helped

strengthen international Communism. These textual manipulations, moreover, led to an unresolved controversy concerning the initial intent of Mao's speech.

The leadership's explanation was that Mao had set out to trap the dangerous elements among the intellectuals by encouraging their criticism of the party and government. An alternative view was that the leaders used the metaphor of the trap to rationalize their reaction to the unanticipated criticism, popular demonstrations, and general antiparty sentiments expressed in the late spring, when the term "hundred flowers" gained international currency. Whatever the correct explanation for these significant textual changes, the Communist leaders had encouraged free criticism of the party and its programs, and they had then turned on their critics as rightists and counterrevolutionaries. In June non-Communists who had thrown caution to the winds reaped the full fury of retaliation in an antirightist campaign. The intellectuals who had responded to Mao's call for open criticism were the first victims, but the movement quickly spread beyond that group to engulf many specialists in the government bureaucracy and state-run firms. By the fall the fury of the campaign began to turn toward the countryside, and those, especially among the rural cadres, who had remained unenthusiastic about the "high tide" of agricultural change came under fire and were removed. The spreading antirightist campaign then inspired fear in those who wanted a slower, more pragmatic approach to development and shifted the initiative to others who, like Mao, believed that the solutions to China's core problems lay in a major break with the incrementalist Soviet strategy and in a bold new set of distinctly Chinese ideas. International events dovetailed with this basic thrust by the winter of 1957–58.

Foreign policy. While taking their principal cues in their foreign policies from domestic developments and generally adhering to the initial pro-Soviet line, the Chinese began to act—on the basis of several important lessons gained during the Korean struggle—to reduce Peking's militant and isolationist attitudes in international affairs. Peking had recognized that the great costs of the war, the questionable reliability of Soviet military backing, and the danger of direct U.S. retaliation against China had come close to threatening its very existence. Although in preserving North Korea as a Communist state China had attained its principal strategic objective, its leaders understood the costs and risks involved and were determined to exercise a greater caution in their international dealings. Another lesson was that the neutralist states in Asia and Africa were not Western puppets, and it was politically profitable to promote friendly relations with them. These lessons, as reinforced by domestic considerations, led China to take a conciliatory role in the Geneva Conference on Indochina in 1954 and to try to normalize its foreign relations.

Lessons from the Korean War

Premier Zhou Enlai symbolized China's more active diplomatic role at the Asian-African Conference held at Bandung, Indon., in April 1955. His slogan was "unity with all," according to the line of peaceful coexistence. This "Bandung line" associated with Zhou gained worldwide attention when he told the Bandung delegates that his government was fully prepared to achieve normal relations with all countries, including the United States. As a result of his initiative, ambassadorial talks between China and the United States were begun.

Between 1955 and 1957, however, changes in Soviet and U.S. policies caused Chinese leaders to doubt the validity of this more cautious and conciliatory foreign policy. At the 20th Congress of the Soviet Communist Party in 1956, Party Secretary Nikita Khrushchev announced a de-Stalinization policy. This development angered Mao Zedong for two reasons: he thought, correctly, that it would undermine Soviet prestige, with potentially dangerous consequences in eastern Europe, and he chafed at Khrushchev's warning to other Communist parties not to let a willful leader have his way unchecked. Thus, a new situation in Sino-Soviet relations began to emerge, in which antagonisms based on different national traditions, revolutionary experiences, and levels of development that had previously been glossed over broke through to the surface.

Chinese leaders—Mao foremost among them but by no means alone—now began to question the wisdom of closely following the Soviet model. Economic difficulties provided a major set of reasons for moving away from that model, and increasing mutual distrust exacerbated the situation. Nevertheless, at the end of 1957 the Soviet Union evidently agreed to provide China with the technical assistance needed to make an atomic bomb, and during 1958 the Soviet Union increased its level of aid to China. In the final analysis, however, the spiral of deterioration in Sino-Soviet relations proved impossible to reverse.

China adopted a new, more militant foreign policy that can be traced most clearly to Mao's statement during a Moscow trip in November 1957 that the "East wind prevails over the West wind." This implied a return to militant struggle. According to some estimates, the change in line was necessitated by the U.S. buildup of anti-Communist regimes to encircle China and by the lack of major gains in peaceful coexistence with Third World neutrals. Other analysts argue that Mao regarded the launching of a Soviet space vehicle (October 1957) and the Sino-Soviet nuclear-sharing agreement as indications that the balance of world forces had changed in favour of Communism.

Return to a militant struggle

New directions in national policy, 1958–61. The pressures behind the dramatic inauguration in 1958 of "Three Red Banners"—the general line of socialist construction, the Great Leap Forward, and the rural people's communes—are still not fully known. Undoubtedly, a complex mixture of forces came into play. Mao personally felt increasingly uncomfortable with the alliance with the Soviet Union and with the social and political ramifications of the Soviet model of development. On ideological grounds and because it shifted policy away from his personal political strengths, Mao disliked the Soviet system of centralized control by large government ministries, substantial social stratification, and strong urban bias. In addition, the Soviet model assumed that agricultural surplus need only be captured by the government and made to serve urban development. This was true for the Soviet Union in the late 1920s, when the model was developed, but the situation in China was different. Chinese policy had to devise a way first to create an agricultural surplus and then to take a large part of it to serve urban growth. The Soviet model also rested on implicit assumptions about the energy and transportation sectors that were not compatible with the Chinese realities of the 1950s.

To some extent, obscure political battles also became caught up in the debates over Chinese development strategies. In the spring of 1958, for example, Mao Zedong elevated Marshal Lin Biao (Lin Piao) to a higher position in the CCP than that held by Defense Minister Peng Dehuai (P'eng Te-huai). At the same time, Mao initiated a critique of China's slavish copying of Soviet military strategy. Peng bore the brunt of this criticism because he had advocated close military ties with the Soviet Union.

Overall, the radicalization of policy that led to the Great Leap Forward can be traced back to the antirightist campaign of 1957 and a major meeting of China's leaders at the resort city of Tsingtao in October of that year. By the time of another central meeting—this one in Nan-ning in January 1958—Mao felt confident enough to launch a blistering critique of the domination of economic policy by the State Council and its subordinate ministries. The best available evidence suggests that almost all of the top leaders supported Mao as he developed a series of initiatives that eventually produced the Great Leap strategy and the people's communes. The only major exceptions appear to have been Zhou Enlai and Chen Yun (Ch'en Yün), a force in Chinese economic policy; both faded from the public eye in 1958 only to be brought back into active roles as the Great Leap faltered in 1959.

The general line of socialist construction and the Great Leap Forward were announced at the second session of the Eighth Party Congress (May 1958), which concentrated as much on political slogans as on specific objectives. Special emphasis was placed on political guidance by party cadres of the country's scientists and technicians, who were viewed as potentially dangerous unless they would become fully "Red and expert." The progressive indoctrination

Great Leap Forward

of experts would be paralleled by introductory technical training for cadres, thereby in theory transforming the entire elite into political-technical generalists. The Congress of 1958 called for a bold form of ideological leadership that could unleash a "leap forward" in technical innovation and economic output. To link the new generalist leaders and the masses, emphasis fell on sending cadres to the lower levels (*hsia-fang*) for firsthand experience and manual labour and for practical political indoctrination.

The Great Leap Forward involved an enormous amount of experimentation. It had no detailed blueprint, but there were some underlying strategic principles. There was a general reliance on a combination of ideological and organizational techniques to overcome seemingly insuperable obstacles that was focused on the countryside and that drew from policies of the 1930s and '40s. The basic idea was to convert the massive labour surplus in China's hinterlands into a huge production force through a radical reorganization of rural production. The search for the best organizational form to achieve this result led in August 1958 to popularization of the "people's commune," a huge rural unit that pooled the labour of tens of thousands of peasants from different villages in order to increase agricultural production, engage in local industrial production, enhance the availability of rural schooling, and organize a local militia force in accordance with Mao's preferred national military strategy of combining the deterrence of an atomic bomb with guerrilla warfare.

Mao believed that through these radical organizational changes, combined with adequate political mobilization techniques, the Chinese countryside could be made to provide the resources both for its own development and for the continuing rapid development of the heavy industrial sector in the cities. Through this strategy of "walking on two legs," China could obtain the simultaneous development of industry and agriculture and, within the urban sector, of both large- and small-scale industry. If it worked, this would resolve the dilemma of an agricultural bottleneck that had seemed to loom large on the horizon as of 1957. It would, however, involve a major departure from the Soviet model, which would predictably lead to increased tensions between Peking and Moscow.

Largely because of unusually good weather, 1958 was an exceptionally good year for agricultural output. But, by the end of that year, the top CCP leadership sensed that some major problems demanded immediate attention. Initial optimism had led peasants in many areas to eat far more than they usually would have, and stocks of grain for the winter and spring months threatened to fall dangerously low. In addition, reports of sporadic peasant unrest cast some doubt on the rosy picture being presented to the leaders by their own statistical system, the accuracy of which, in turn, came into question.

The fall harvest of 1958 had not been as large as expected, and in February and March 1959 Mao Zedong began to call for appropriate adjustments to make policies more realistic without abandoning the Great Leap as a whole. Mao emerged as one of the most forceful advocates of scaling back the Great Leap in order to avert a potential disaster. He faced substantial resistance from provincial CCP leaders whose powers had been greatly increased as part of the Great Leap strategy. A meeting at Lu-shan in the summer of 1959 produced an unanticipated and ultimately highly destructive outcome. Defense Minister Peng Dehuai raised a range of criticisms of the Great Leap, based in large part on his own investigations. He summed these up in a letter that he sent to Mao during the conference. Mao waited eight days to respond to the letter and then attacked Peng for "right deviationism" and demanded the purge of Peng and all his followers.

The Lu-shan Conference resulted in several major decisions: Peng Dehuai was replaced with Lin Biao, who would later be marked for succession to Mao's position of CCP chairman; the Great Leap Forward was scaled back; and a political campaign was launched to identify and remove all "rightist" elements. The third decision effectively canceled the second, as party officials refused to scale back the Great Leap for fear of being labeled as "rightists." The net effect was to produce a "second leap"—a new radical upsurge in policy that was not corrected until it produced results so disastrous that they called into question the very viability of the Communist system.

The CCP celebrated the 10th anniversary of national victory in October 1959 in a state of near euphoria. The weather turned in 1959, however, and during the next two years China experienced a severe combination of floods and drought. Although the economy was in serious trouble by mid-1960, the Chinese leaders sharpened their debate with Moscow. In April 1960, on the occasion of Lenin's 90th birthday, for example, Peking published an article that contained a slightly veiled critique of Soviet foreign policy, arguing that the Soviets had become soft on imperialism. Khrushchev reacted with a rapid withdrawal of all Soviet technicians and assistance that July. (When he quietly offered to return them that November, his offer was refused.)

Failure of the Great Leap

Despite the importance of these difficulties, China's worst problem was bad policy. The people's communes were too large to be effective, they ignored age-old marketing patterns in the countryside, and they required administrative and transport resources that did not exist. Their structure and means of allocating resources removed almost all incentive to work, and the breakdown in the statistical system meant that the top leaders had grossly erroneous ideas about what was occurring. Thus, even after massive starvation had beset many rural areas, the orders from above continued to demand large-scale procurement of foodstuffs. The rural cadres were so afraid of being branded rightist that they followed these unrealistic orders, thus deepening the famine. By 1961 the rural disaster caught up with the cities, and urban industrial output plummeted by more than 25 percent. As an emergency measure, nearly 30,000,000 urban residents were sent back to the countryside because they could no longer be fed in the cities. The Great Leap Forward had run its course and the system was in crisis.

Readjustment and reaction, 1961–65. The years 1961–65 did not resemble the three previous ones, despite the persistence of radical labels and slogans. The Chinese themselves were loath to acknowledge the end of the Great Leap period, declaring the validity of the general line of socialist construction and its international revolutionary corollary for one and all.

Reality can be seen, however, in the increasing role of the Chinese military and security personnel. At a top-level meeting of the Military Affairs Committee in October 1960 and at one of the rare plenary sessions of the party's Central Committee the following January, the elite gave the highest priority to the restoration of security and national order. Party recruitment procedures were tightened, and a major thought-reform movement was launched within the cadres' ranks. The Central Committee also established six supraprovincial regional bureaus charged with enforcing obedience to Peking and bringing the new procedures for control into line with local conditions. The army, now firmly under Lin Biao, took the lead, beginning with a "purification" movement against dissidents within its own ranks. Throughout 1961 and most of 1962 the central officials worked to consolidate their power and to restore faith in their leadership and goals.

By January 1962 Mao had, as he later put it, moved to the "second line" to concentrate "on dealing with questions of the direction, policy, and line of the party and the state." The "first-line" administrative and day-by-day direction of the state had been given to Liu Shaoqi, who had assumed the chairmanship of the People's Republic of China in 1959 (though Mao retained his position of party chairman); additional responsibilities in the first line were given to Deng Xiaoping (Teng Hsiao-p'ing), another tough-minded organizer who, as general secretary, was the party's top administrator. By 1962 Mao had apparently begun to conclude that the techniques used by these comrades in the first line not only violated the basic thrust of the revolutionary tradition but also formed a pattern of error that mirrored what he viewed as the "modern revisionism" of the Soviet Union.

Rise of Liu Shaoqi and Deng Xiaoping

Under Liu and Deng, the CCP during 1960–61 developed a series of documents in major policy areas to try to

bring the country out of the rapidly growing crisis. In most instances, the drafting of these documents was done with the assistance of experts who had been reviled during the Great Leap Forward. These documents marked a major retreat from Great Leap radicalism. The communes were to be reduced on the average by about two-thirds so as to make them small enough to link peasants' efforts more clearly with their remuneration. Indeed, by 1962 in many areas of rural China the collective system in agriculture had broken down completely and individual farming was revived. Policy toward literature, art, and motion pictures permitted a "thaw" involving treatment of a far broader range of subjects and revival of many older, prerevolutionary artistic forms. The new program in industry strengthened the hands of managers and made a worker's efforts more closely attuned to his rewards. Similar policies were adopted in other areas. In general, over the years 1961–65 a remarkable job of reviving the economy succeeded in at least regaining the level of output of 1957 in almost all sectors.

These policies raised basic questions about the future direction of the revolution. While almost all top CCP leaders had supported the launching of the Great Leap, there was disagreement over the lessons to be learned from the movement's dramatic failure. The Great Leap had been intended both as a means of accelerating economic development and as a vehicle for achieving a mass ideological transformation. All leaders agreed in its aftermath that a mobilization approach to economic development was no longer appropriate to China's conditions. Most also concluded that the age of mass political campaigns as an instrument to remold the thinking of the public was past. Mao and a few of his supporters, however, still viewed class struggle and mass mobilization as core ingredients in keeping the revolutionary vision alive.

Mao personally lost considerable prestige over the failure of the Great Leap—and the party's political and organizational apparatus was damaged—but he remained the most powerful individual in China. He proved able time and again to enforce his will on the issues that he deemed to be of top priority. Claims made during the Cultural Revolution that Mao had been pushed aside and ignored during 1962–65 are not supported by the evidence.

Mao was in fact deeply troubled as he contemplated China's situation during 1961–65. He perceived the Soviet Socialist revolution in the years after Stalin's death in 1953 to have degenerated into "social imperialism." Mao evidently had been shocked by these developments in the Soviet Union, and the revelation made him look at events in China from a new vantage point. Mao became convinced that China, too, was headed down the road toward revisionism. He used class struggle and ideological campaigns, as well as concrete policies in various areas, to try to prevent and reverse this slide into revolutionary purgatory. Mao's nightmare about revisionism played an increasing role in structuring politics in the mid-1960s.

Fears of revisionism

Mao was not the only leader who harboured doubts about the trends in the recovery effort of 1961–65. Others gathered around him and tried to use their closeness to Mao as a vehicle for enhancing their political power. The key individuals involved were Mao's political assistant of many years, Chen Boda (Ch'en Po-ta), who was an expert in the realm of ideology; Mao's wife, Jiang Qing (Chiang Ch'ing), who had strong policy views in the cultural sphere; Kang Sheng (K'ang Sheng), whose strength lay both in his understanding of Soviet ideology and in his mastery of Soviet-style secret police techniques; and Lin Biao, who headed the military and tried to make it an ideal type of Maoist organization that combined effectiveness with ideological purity. Each of these people, in turn, had personal networks and resources to bring to a coalition. While their goals and interests did not entirely coincide, they all could unite on two efforts—enhancing Mao's power and upsetting Mao's relations with Liu Shaoqi (then the likely successor to Mao), Deng Xiaoping, and most of the remainder of the party leadership.

Mao took a number of initiatives in domestic and foreign policy during the mid-1960s. At a major Central Committee plenum in September 1962 he insisted that "class struggle" remain high on the Chinese agenda, even as enormous efforts continued to be made to revive the economy. He also called for a campaign of "socialist education," aimed primarily at reviving the demoralized party apparatus in the countryside. By 1964 he began to press hard to make the Chinese educational system less elitist by organizing "part-work, part-study" schools that would provide more vocational training. Throughout this period, foreign observers noted what appeared to be some tension between a continuing thread of radicalism in China's propaganda and a strong pragmatic streak in the country's actual domestic policies.

The most important set of measures Mao took concerned the People's Liberation Army (PLA), which he and Lin Biao tried to make into a model organization. Events on the Sino-Indian border in the fall of 1962 helped the PLA reestablish discipline and its image. From 1959 to 1962 both India and China, initially as a by-product of the uprising in Tibet, resorted to military force along their disputed border. On Oct. 12, 1962, a week before the Chinese moved troops into disputed border territories, Indian Prime Minister Jawaharlal Nehru stated that the army was to free all Indian territory of "Chinese intruders." In the conflict that followed, Peking's regiments defeated the Indian Army in the border region, penetrating well beyond it. The Chinese then withdrew from most of the invaded area and established a demilitarized zone on either side of the line of control. Most significantly, the leadership seized on the army's victory and began to experiment with the possibility of using army heroes as the ideal types for popular emulation.

Dispute with India

Increasingly preoccupied with indoctrinating its heirs and harking back to revolutionary days, Peking's leaders closest in outlook to Mao Zedong and Lin Biao viewed the soldier-Communist as the most suitable candidate for the second- and third-generation leadership. Army uniformity and discipline, it was seen, could transcend the divided classes, and all army men could be made to comply with the rigorous political standards set by Mao's leadership.

Lin Biao developed a simplified and dogmatized version of Mao's thought, eventually published in the form of the "little red book," *Quotations from Chairman Mao,* to popularize Maoist ideology among the relatively uneducated military recruits. As the military forces under Lin increasingly showed that they could combine ideological purity with technical virtuosity, Mao tried to expand the PLA's organizational authority and its political role. Beginning in 1963, Mao called on all Chinese to "learn from the PLA." Then, starting in 1964, Mao insisted that political departments modeled on those in the PLA be established in all major government bureaucracies. In many cases, political workers from the PLA itself staffed these new bodies, thus effectively penetrating the civilian government apparatus. Other efforts, such as a national propaganda campaign to learn from a purported army hero, Lei Feng, also contributed to enhancement of the PLA's prestige.

The militancy of subsequent campaigns to learn from army heroes, or from the PLA as a whole, was echoed in international politics. In a tour of Africa in late 1963 and early 1964, Zhou Enlai startled his hosts by calling for revolution in newly independent states and openly challenged the Soviet Union for the leadership of the Third World. Simultaneously, China challenged the U.S. system of alliances by establishing formal relations with France and challenged the Soviet Union's system by forming closer ties with Albania.

Peking's main target was Moscow. A Soviet-U.S. crisis in Cuba (October 1962) had coincided with the Sino-Indian struggle, and in both cases the Chinese believed the Soviet Union had acted unreliably and had become "capitulators" of the worst sort. For the next months polemicists in Peking and Moscow publicly engaged in barbed exchanges. When the Soviet Union signed a partial Nuclear Test-Ban Treaty with the United States and Great Britain in July 1963, Chinese articles accused the Soviets of joining an anti-Chinese conspiracy. Confronted by this new strategic situation, the Chinese shifted their priorities to support an antiforeign line and to promote the country's "self-reliance." Mao's calls for "revolutionization" acquired a

The end of Sino-Soviet unity

more nationalistic aspect, and the PLA assumed an even larger place in Chinese political life.

These many-sided trends seemed to collide in 1963 and 1964. With the split in the international Communist movement, the party in late 1963 called on intellectuals, including those in the cultural sphere, to undertake a major reformulation of their academic disciplines to support China's new international role. The initial assignment for this reformulation fell to Zhou Yang (Chou Yang), a party intellectual and deputy director of the Central Committee's Propaganda Department, who tried to enlist China's intellectuals in the ideological war against Soviet revisionism and in the struggle for rigidly pure political standards. (Less than three years later, however, Zhou Yang was purged as a revisionist, and many intellectuals were condemned as Mao Zedong's opponents.)

Closely connected with the concerns of the intellectuals were those relating to the party and the Communist Youth League. A drive began to cultivate what one author called "newborn forces," and by mid-1964 young urban intellectuals were embroiled in a major effort by the Central Committee to promote those forces within the party and league; meanwhile their rural cousins were buffeted by moves to keep the socialist education campaign under the party's organizational control through the use of "work teams" and a cadre-rectification movement.

Mao in the summer of 1964 wrote a document entitled "On Khrushchev's Phony Communism and Its Historical Lessons for the World," which summarized most of Mao's doctrinal principles on contradiction, class struggle, and political structure and operation. This summary provided the basis for the reeducation ("revolutionization") of all youth hoping to succeed to the revolutionary cause. This high tide of revolutionization lasted until early August, when U.S. air strikes on North Vietnam raised the spectre of war on China's southern border. A yearlong debate followed on the wisdom of conducting disruptive political campaigns during periods of external threat.

This period has come to be interpreted as a time of major decision within China. One ingredient of the debate was whether to prepare rapidly for conventional war against the United States or to continue the revolutionization of Chinese society, which in Mao's view had fundamental, long-term importance for China's security. Those who argued for a postponement of the internal political struggle supported more conventional strategies for economic development and took seriously Soviet calls for "united action" in Vietnam and the establishment of closer Sino-Soviet ties. Their position, it was later alleged, received the backing of the general staff. With the dispatch of about 50,000 logistic personnel to Vietnam after February 1965, factional lines began to divide the military forces according to ideological or national-security preferences.

Effects of the war in Indochina

Meanwhile, some members tried to restore rigid domestic controls. Where Mao in May 1963 had called for an upsurge in revolutionary struggle, other leaders in the following September circumscribed the area of cadre initiative and permitted a free-market system and private ownership of rural plots to flourish. A stifling of the revolutionary upsurge was supposedly evident in regulations of June 1964 for the organization of poor and lower-middle-peasant associations, and by early 1965 Mao could point to bureaucratic tendencies throughout the rural areas. In a famous document on problems arising in the course of the socialist education campaign, usually referred to as the "Twenty-three Articles," Mao in January 1965 stated, for the first time, that the principal enemy was to be found within the party and once more proclaimed the urgency of class struggle and mass-line politics.

It was in this period of emphasis on self-reliant struggle that China acquired nuclear weapons. Although the Soviet Union supported Chinese nuclear aims for a time, this effort was taken over completely by the Chinese after June 1959. By 1964 the costs of the program had forced a substantial reduction in other defense costs. China's first atomic explosion (Oct. 16, 1964) affected the debate by appearing to support Mao's contention that domestic revolutionization would in no way jeopardize long-term power aspirations and defense capabilities.

China's first atomic explosion

Mao's military thinking, a product of his own civil war experiences and an essential component of his ideology, stressed the importance of people's war during the transition to nuclear status. He felt that preparation for such a war could turn China's weaknesses into military assets and reduce its vulnerability. Mao's view of people's war belittled the might of modern advanced weapons as "paper tigers" but recognized that China's strategic inferiority subjected it to dangers largely beyond its control. His reasoning thus made a virtue out of necessity in the short run, when China would have to depend on its superior numbers and the morale of its people to defeat any invader. In the long run, however, he held that China would have to have nuclear weapons to deprive the superpowers of their blackmail potential and to deter their aggression against smaller states.

Lin Biao repeated Mao's position on people's war, further arguing that popular insurrections against non-Communist governments could succeed only if they took place without substantial foreign assistance. To the extent that indigenous rebels came to depend on outside support, inevitably their bonds with the local populace would be weakened. When this happened, the rebellion would wither for lack of support. On the other hand, the hardships imposed by relying on indigenous resources would stimulate the comradeship and the ingenuity of the insurgents. Equally important, Lin's statement also indicated a high-level decision for China to remain on the defensive.

Lin's speech coincided with yet another secret working conference of the Central Committee, in which the Maoist group reissued its call for cultural revolutionization, this time convinced that the effort of 1964 had been deliberately sabotaged by senior party and military officials. Initiated by Mao Zedong and Lin Biao, the purge first struck dissident army leaders, especially the chief of staff; and as the power struggle began, China turned its back on the war in Vietnam and other external affairs. The September meeting may be taken as a clear harbinger of the Great Proletarian Cultural Revolution.

THE CULTURAL REVOLUTION, 1966–76

As the clash over issues in the autumn of 1965 became polarized, the army initially provided the battleground. The issues concerned differences over policy directions and their implications for the organization of power and the qualifications of senior officials to lead. Much of the struggle went on behind the scenes; in public it took the form of personal vilification and ritualized exposés of divergent worldviews or, inevitably, "two lines" of policy. Lin Biao, in calling for the creative study and application of Mao's thought in November and at a meeting of military commissars the following January, consistently placed the army's mission in the context of the national ideological and power struggle. In these critical months the base of operations for Mao and Lin was the large eastern Chinese city of Shanghai; and newspapers published in that city, especially the *Liberation Army Daily,* carried the public attacks on the targets selected.

Attacks on cultural figures. The first target was the historian Wu Han, who doubled as the deputy mayor of Peking. In a play, Wu supposedly had used allegorical devices to lampoon Mao and laud the deposed former minister of defense, Peng Dehuai. The denunciation of Wu and his play on Nov. 10, 1965, constituted the opening volley in an assault on cultural figures and their thoughts.

As the Cultural Revolution gained momentum, Mao turned for support to the youth as well as the army. In seeking to create a new system of education that would eliminate differences between town and country, workers and peasants, and mental and manual labour, Mao struck a responsive chord within the youth; it was their response that later provided him with his best shock troops. As a principal purpose, the Cultural Revolution was launched to revitalize revolutionary values for the successor generation of Chinese young people.

Mao on education

During the spring of 1966 the attack against authors, scholars, and propagandists emphasized the cultural dimension of the Cultural Revolution. Increasingly it was hinted that behind the visible targets lay a sinister "black

gang" in the fields of education and propaganda and high up in party circles. Removal of Peng Zhen (P'eng Chen) and Lu Dingyi (Lu Ting-yi) and subsequently of Zhou Yang, then tsar of the arts and literature, indicated that this was to be a thoroughgoing purge. Clearly, a second purpose of the Cultural Revolution would be the elimination of leading cadres whom Mao held responsible for past ideological sins and alleged errors in judgment.

Attacks on party members. Gradual transference of the revolution to top echelons of the party was managed by a group centred on Mao Zedong, Lin Biao, Jiang Qing, Kang Sheng, and Chen Boda. In May 1966 Mao secretly assigned major responsibilities to the army in cultural and educational affairs. Another purpose of the Cultural Revolution, as then conceived, would be a "revolution in the superstructure": a transformation from a bureaucratically run machine to a more popularly based system led personally by Mao and a simplified administration under his control.

Following the May instructions, the educational system received priority. "Big-character posters," or large wall newspapers (*ta-tzu-pao*), spread from the principal campuses in Peking throughout the land. University officials and professors were singled out for criticism, while their students, encouraged by the central authorities, held mass meetings and began to organize. In June the government dropped examinations for university admissions and called for a reform of entrance procedures and a delay in reopening the campuses. Party officials and their wives circulated among the campuses to gain favour and to obstruct their opponents. Intrigue and political maneuvering dominated, although political lines were not at first sharply drawn or even well understood. The centres of this activity were Peking's schools and the inner councils of the Central Committee; the students were the activists in a game they did not fully comprehend.

This phase of the Cultural Revolution ended in August 1966 with the convening of a plenary session of the Central Committee. Mao issued his own big-character poster to "Bombard the Headquarters," a call for the denunciation and removal of senior officials, and a 16-point Central Committee decision was issued, in which the broad outlines for the Cultural Revolution were laid down and supporters were rallied to the revolutionary banner. The immediate aim was to seize power from "bourgeois" authorities. The locus of the struggle would be their urban strongholds. Now more than ever, Mao's thought became the "compass for action." (J.W.Le./K.G.L.)

Evidently fearing that China would develop along the lines of the Soviet revolution, and concerned about his own place in history, Mao threw China's cities into turmoil in a gigantic effort to reverse the historic processes then under way. He ultimately failed in his quest, but his efforts generated problems with which his successors would have to struggle for decades. Mao adopted four goals for his Cultural Revolution: to replace his designated successors with leaders more faithful to his current thinking, to rectify the CCP, to provide China's youth with a revolutionary experience, and to achieve specific policy changes to make the educational, health-care, and cultural systems less elitist. He initially pursued those goals through a massive mobilization of the country's urban youths—organized in groups called the Red Guards—while ordering the CCP and the PLA not to suppress the movement.

The Red Guards

When Mao formally launched the Cultural Revolution in August 1966, he had already shut down the schools. During the following months he encouraged the Red Guards to attack all traditional values and "bourgeois" things and to put CCP officials to the test by publicly criticizing them. These attacks were known at the time as struggles against the Four Olds (*i.e.,* old ideas, customs, culture, and habits of mind), and the movement quickly escalated to the committing of outrages. Many elderly people and intellectuals were physically abused, and many died. Nonetheless, Mao believed that this mobilization of urban youths would be beneficial for them and that the CCP cadres they attacked would be better for the experience.

Seizure of power. The period from mid-1966 to early 1969 constituted the Red Guard phase of the Cultural Revolution, and these years in turn included several important turning points. The latter half of 1966 witnessed not only the Red Guard mobilization (including Red Guard reviews of more than 1,000,000 youths at a time by Mao Zedong and Lin Biao in Peking) but also the removal from power of key Political Bureau (Politburo) leaders, most notably Pres. Liu Shaoqi and CCP General Secretary Deng Xiaoping. In October 1966 both Liu and Deng engaged in public self-criticism. Mao, however, rejected both acts as inadequate. At the same meeting, Mao heard bitter complaints from provincial party leaders about the chaos of the political campaign. While acknowledging the validity of much of what was said, Mao nevertheless declared that it would do more good than harm to let the Cultural Revolution continue for several more months.

In January 1967 the movement began to produce the actual overthrow of provincial CCP committees and initial attempts to construct new organs of political power to replace them. The first such "power seizure" took place in Shanghai and was followed by temporary confusion as to just what kind of new political structure should be established to replace the discredited municipal CCP and government apparatuses. The final form adopted was called a "revolutionary committee," and that appellation was given to Chinese government committees until the late 1970s.

The chaos involved in the overthrow of the Shanghai authorities combined with political outrages throughout the country to lead many remaining top CCP leaders to call in February 1967 for a halt to the Cultural Revolution. During this attempt to beat back radicalism, more conservative forces clamped down on Red Guard activism in numerous cities. The movement, dubbed the "February adverse current," was quickly defeated and a new radical upsurge began. Indeed, by the summer of 1967 large armed clashes occurred throughout urban China, and even Chinese embassies abroad experienced takeovers by their own Red Guards. The Red Guards splintered into zealous factions, each purporting to be the "true" representative of the thought of Mao Zedong. Mao's own personality cult, encouraged so as to provide momentum to the movement, assumed religious proportions. The resulting anarchy, terror, and paralysis threw the urban economy into a tailspin. Industrial production for 1968 dipped 12 percent below that of 1966.

Intervention of the PLA

During 1967 Mao called on the PLA under Lin Biao to step in on behalf of the Maoist Red Guards, but this politico-military task produced more division within the military than unified support for radical youths. Tensions surfaced in the summer, when Chen Zaidao (Ch'en Tsai-tao), a military commander in the key city of Wu-han, arrested two key radical CCP leaders. Faced with possible widespread revolt among local military commanders, Mao tilted toward the reestablishment of some order.

In 1968 Mao decided to rebuild the CCP and bring things under greater control. The military dispatched officers and soldiers to take over schools, factories, and government agencies. The army simultaneously forced millions of urban Red Guards to move to the hinterlands to live, thereby removing the most disruptive force from the cities. These drastic measures reflected Mao's disillusionment with the Red Guards' inability to overcome factional differences. The Soviet invasion of Czechoslovakia in August 1968, which greatly heightened China's fears for its security, gave these measures added urgency.

The end of the radical period. Thus in 1968 the society began to return to business, though not as usual. China's regular schools began to reopen, although the number of students in higher institutions represented only a small percentage of those three years before. In July yet another of Mao's "latest instructions" approved science and engineering education and called for the "return to production" of all graduates. In October 1968 a plenary session of the Central Committee met to call for the convening of a party congress and the rebuilding of the CCP apparatus. From that point on, the issue of who would inherit political power as the Cultural Revolution wound down became a central question of Chinese politics. (The answer came only with a coup against the radicals a month after Mao Zedong's death on Sept. 9, 1976.)

Fears of Soviet invasion

China's actions following the meeting of October 1968 suggested the degree to which fear of a Soviet invasion contributed to the closing down of the Cultural Revolution's most radical phase. Almost immediately after the meeting, China called on the United States to resume ambassadorial-level talks in Warsaw. Peking also renewed its conventional diplomacy—it had reduced its level of ambassadorial representation abroad to a single ambassador in Egypt—and quickly sought to expand the range of countries with which it enjoyed diplomatic relations.

China's concern stemmed partly from the Soviet leadership's articulation of the Brezhnev Doctrine in the wake of the invasion of Czechoslovakia. That doctrine explained the invasion in terms of the obligation of the Soviet Union and other Socialist countries to set things right if "scientific socialism" became threatened in any country in which a Communist Party had held power. To Peking's horror, even Hanoi came out in support of this threatening posture. Moscow had long made clear that it believed that a "military-bureaucratic dictatorship" had seized power from the "true Communists" in Peking. To add to Peking's concern, since 1966 the Soviet Union had been building up a sizable military force along the formerly demilitarized Sino-Soviet border. While the forces deployed as of late 1968 were not adequate for a full-scale invasion of China, they certainly posed a serious menace, especially given the political division and social chaos that still prevailed in much of the country.

When the Party Congress convened in April 1969, it did so in the wake of two bloody Sino-Soviet border clashes that had occurred in early and mid-March. Written into the new party constitution was an unprecedented step—Defense Minister Lin Biao was named as Mao's successor—and the military tightened its grip on the entire society. Both the Central Committee and the new party committees being established throughout the country were dominated by military men. Indeed, less than 30 percent of the Eighth Central Committee members elected in 1956 were reelected in 1969, and more than 40 percent of the members of the Ninth Central Committee chosen in 1969 held military posts.

Premier Zhou Enlai tried to cut back Lin Biao's power and to relieve some of the threat to China's security by engaging the Soviets in direct negotiations on the border dispute. A series of serious military clashes along the border, culminating in a limited but sanguinary Soviet thrust several miles into the Uighur Autonomous Region of Sinkiang, heightened tensions. Zhou briefly met with Soviet Premier Aleksey Kosygin at the Peking airport in early September, and the two agreed to hold formal talks. Nevertheless, Lin Biao declared martial law and used it to rid himself of some of his potential rivals. Several leaders who had been purged during 1966–68, including Liu Shaoqi, died under the martial law regime of 1969, and many others suffered severely.

Lin quickly encountered opposition, however. Mao became wary of a successor who seemed to want to assume power too quickly and began to maneuver against Lin. Premier Zhou Enlai joined forces with Mao in that effort, as possibly did Mao's wife, Jiang Qing. Mao's assistant, Chen Boda, decided to support Lin's cause, however. Therefore, while in 1970–71 many measures were undertaken to bring order and normalcy back to society, increasingly severe strains split the top leadership.

Social changes. By 1970 many of the stated goals of the Cultural Revolution had been translated into at least somewhat operational programs. These included initiatives designed to reduce what were termed the "three major differences"—those separating intellectual from manual labour, worker from peasant, and urban from rural.

Many measures had been taken to make the educational system less elitist. The number of years at each level of schooling was shortened, and admission to a university became based on the recommendations of a student's work unit rather than on competitive examination. All youths were required to engage in at least several years of manual labour before attending a university. Within schools, formal scholarship yielded in large measure to the study of politics and to vocational training. Examinations of the traditional type were abolished, and stress was placed on collective study. The authority of teachers in the classroom was seriously eroded. These trends reached their most extreme form when a student in the Northeast was made a national hero by the radicals because he turned in a blank examination paper and criticized his teacher for having asked him the examination questions in the first place.

The rustication program

Many bureaucrats were forced to leave the relative comfort of their offices for a stint in "May 7 cadre schools," usually farms run by a major urban unit. People from the urban unit had to live on the farm, typically in quite primitive conditions, for varying periods of time. (For some, this amounted to a number of years, although by about 1973 the time periods in general had been held to about six months to one year.) While on the farm the urban cadre would both engage in rigorous manual labour and undertake intensive, supervised study of ideology. The object was to reduce bureaucratic "airs."

Millions of Chinese youths were also sent to the countryside during these years. Initially, these were primarily Red Guard activists, but the program soon achieved a more general character, and it became expected that most middle-school graduates would head to the countryside. While in the hinterlands, these young people were instructed to "learn from the poor and lower middle peasants." Quite a few of these people were merely sent to the counties immediately adjacent to the city from which they came. Others, however, were sent over very long distances. Large groups from Shanghai, for instance, were made to settle in Sinkiang. This rustication was, in theory, permanent, although the vast majority of these people managed to stream back to the cities in the late 1970s, after Mao's death and the purge of his radical followers.

The system of medical care was also revamped. Serious efforts were made to force urban-based medical staffs to devote more effort to serving the needs of the peasants. This involved both the reassignment of medical personnel to rural areas and, more importantly, a major attempt to provide short-term training to rural medical personnel called "barefoot doctors." This latter initiative placed at least a minimal level of medical competence in many Chinese villages, and ideally the referral of more serious matters would be made to higher levels. Another prong of the effort in the medical arena was to place relatively greater stress on the use of Chinese traditional medicine, which relied more heavily on locally available herbs and on such low-cost methods as acupuncture. Western medicine was simply too expensive and specialized to be used effectively throughout China's vast hinterlands.

Traditional medicine

The Cultural Revolution was primarily an urban political phenomenon, and thus it had a very uneven effect on the peasants. Some villages, especially those near major cities, became caught up in the turmoil, but many peasants living in more remote areas experienced less interference from higher-level bureaucratic authorities than would normally have been the case.

Nevertheless, there were two dimensions of the Cultural Revolution that did seriously affect peasants' lives. First, the country adopted a policy of encouraging local rural self-sufficiency in foodstuffs. This policy stemmed from ideological and security considerations, and it had begun before the onset of the Cultural Revolution. Its major consequence was a stress on grain production so great that a quite irrational and uneconomical cropping pattern emerged. Second, great stress was placed on separating income from the amount of work performed by a peasant. Pressure was applied to raise the unit of income distribution to the brigade rather than the team (the former was several times larger than the latter), and an increasing share of the collective income was to be distributed on the basis of welfare and political criteria rather than on the basis of the amount of work performed.

Struggle for the premiership. As these programmatic aspects of the Cultural Revolution were being put into place and regularized, the political battle to determine who would inherit power at the top continued and intensified. Tensions first surfaced at a meeting of the Central Committee in the summer of 1970, when Chen Boda, Lin Biao, and their supporters made a series of remarks

that angered Mao Zedong. Mao then purged Chen as a warning to Lin. At the end of 1970 Mao also initiated a criticism of Lin's top supporters in the military forces, calling them to task for their arrogance and unwillingness to listen to civilian authority. The situation intensified during the spring of 1971 until Lin Biao's son, Lin Liguo (Lin Li-kuo), evidently began to put together plans for a possible coup against Mao should this prove the only way to save his father's position.

During this period, Zhou Enlai engaged in extremely delicate and secret diplomatic exchanges with the United States, and Mao agreed to a secret visit to Peking by the U.S. national security adviser Henry Kissinger in July 1971. That visit was one of the most dramatic events of the postwar international arena. At a time when the Vietnam War continued to blaze, China and the United States took major steps toward reducing their mutual antagonism in the face of the Soviet threat. Lin Biao strongly opposed this opening to the United States—probably in part because it would strengthen the political hand of its key architect in China, Zhou Enlai—and the Kissinger visit thus amounted to a major defeat for Lin.

Death of Lin Biao

Finally, in September 1971 Lin was killed in what the Chinese assert was an attempt to flee to the Soviet Union after an abortive assassination plot against Mao. Virtually the entire Chinese high military command was purged in the weeks following Lin's death.

Lin's demise had a profoundly disillusioning effect on many people who had supported Mao during the Cultural Revolution. Lin had been the high priest of the Mao cult, and millions had gone through tortuous struggles to elevate this chosen successor to power and throw out his "revisionist" challengers. They had in this quest attacked and tortured respected teachers, abused elderly citizens, humiliated old revolutionaries, and, in many cases, battled former friends in bloody confrontations. The sordid details of Lin's purported assassination plot and subsequent flight cast all this in the light of traditional, unprincipled power struggles, and untold millions concluded that they had simply been manipulated for personal political purposes.

Initially, Zhou Enlai was the major beneficiary of Lin's death, and from late 1971 through mid-1973 he tried to nudge the system back toward stability. He encouraged a revival and improvement of educational standards and brought numerous people back into office. China began again to increase its trade and other links with the outside world, while the domestic economy continued the forward momentum that had begun to build in 1969. Mao blessed these general moves but remained wary lest they call into question the basic value of having launched the Cultural Revolution in the first place. In Maoist thought it had always been possible for formerly wayward individuals to reform under pressure and again assume power.

During 1972 Mao suffered a serious stroke, and Zhou learned that he had a fatal cancer. These developments highlighted the continued uncertainty over the succession. In early 1973 Zhou and Mao brought Deng Xiaoping back to power in the hope of grooming him as a successor. But Deng had been the second most important victim purged by the radicals during the Cultural Revolution, and his reemergence made Jiang Qing, by then head of the radicals, and her followers desperate to return things to a more radical path. From mid-1973 Chinese politics shifted back and forth between Jiang and her followers—later dubbed the Gang of Four—and the supporters of Zhou and Deng. The former group favoured political mobilization, class struggle, anti-intellectualism, egalitarianism, and xenophobia, while the latter promoted economic growth, stability, educational progress, and a pragmatic foreign policy. Mao tried unsuccessfully to maintain a balance among these different forces while continuing in vain to search for a suitable successor.

Rivalry for succession

The balance tipped back and forth—nudged by Mao first this way, then that—between the two groups. The radicals gained the upper hand from mid-1973 until mid-1974, during which time they whipped up a campaign that used criticism of Lin Biao and of Confucius as an allegorical vehicle for attacking Zhou and his policies. By July 1974, however, economic decline and increasing chaos made Mao shift back toward Zhou and Deng. With Zhou hospitalized, Deng assumed increasing power from the summer of 1974 through the late fall of 1975. During this time Deng sought (with Zhou's full support) to put the Four Modernizations (of agriculture, industry, science and technology, and defense) at the top of the country's agenda. To further this effort Deng continued to rehabilitate victims of the Cultural Revolution, and he commissioned the drafting of an important group of documents much like those developed in 1960–62. They laid out the basic principles for work in the party, industry, and science and technology. Their core elements were anathema to the radicals, who used their power in the mass media and the propaganda apparatus to attack Deng's efforts.

The radicals finally convinced Mao that Deng's policies would lead eventually to a repudiation of the Cultural Revolution and even of Mao himself. Mao therefore sanctioned criticism of these policies in the wall posters that were a favourite propaganda tool of the radicals. Zhou died in January 1976 and Deng delivered his eulogy. Deng then disappeared from public view and was formally purged (with Mao's backing) in April. The immediate reason for Deng's downfall was a group of massive demonstrations in Peking and other cities that took advantage of the traditional Ch'ing-ming festival to pay homage to Zhou's memory and thereby challenge the radicals.

In the immediate wake of Deng's purge, many of his followers also fell from power, and a political campaign was launched to "criticize Deng Xiaoping and his right deviationist attempt to reverse correct verdicts [on people during the Cultural Revolution]." Only Mao's death in September and the purge of the Gang of Four by a coalition of political, police, and military leaders in October 1976 brought this effort to vilify Deng to a close. Although it was officially ended by the 11th Party Congress in August 1977, the Cultural Revolution had in fact concluded with Mao's death and the purge of the Gang of Four.

Consequences of the Cultural Revolution. Although the Cultural Revolution largely bypassed the vast majority of the people, who lived in the rural areas, it had very serious consequences for the Chinese system as a whole. In the short run, of course, the political instability and zigzags in economic policy produced slower economic growth and a decline in the capacity of the government to deliver goods and services. Officials at all levels of the political system had learned that future shifts in policy would jeopardize those who had aggressively implemented previous policy. The result was bureaucratic timidity. In addition, with the death of Mao and the end of the Cultural Revolution, nearly 3,000,000 CCP members and other citizens awaited reinstatement after having been wrongfully purged.

Bold actions in the late 1970s went far toward coping with these immediate problems, but the Cultural Revolution also left more serious, longer-term legacies. First, a severe generation gap had been created in which young adults had been denied an education and had been taught to redress grievances by taking to the streets. Second, there was corruption within the CCP and the government, as the terror and accompanying scarcities of goods during the Cultural Revolution had forced people to fall back on traditional personal relationships and on extortion in order to get things done. Third, the CCP leadership and the system itself suffered a loss of legitimacy when millions of urban Chinese became disillusioned by the obvious power plays that took place in the name of political principle in the early and mid-1970s. Fourth, bitter factionalism was rampant as members of rival Cultural Revolution factions shared the same work unit, each still looking for ways to undermine the power of the other.

Four long-term legacies

CHINA AFTER THE DEATH OF MAO

Perhaps never before in human history had a political leader unleashed such massive forces against the system that he had created. The resulting damage to that system was profound, and the goals that Mao Zedong sought to achieve ultimately remained elusive. The agenda he left behind for his successors was extraordinarily challenging.

Readjustment and recovery. Mao's death and the purge of the Gang of Four left Hua Guofeng (Hua Kuo-feng), a

compromise candidate elevated by Mao after the purge of Deng Xiaoping, as the leader of China. Hua tried to consolidate his position by stressing his ties to Mao and his fidelity to Mao's ideas, but others in the top leadership wanted to move away from these issues, and Hua's position eroded over the remainder of the decade.

The ambivalent legacies of the Cultural Revolution were reflected in the members of the Political Bureau chosen just after the 11th Party Congress had convened in August 1977. Like Hua Guofeng, almost half of the members were individuals whose careers had benefited from the Cultural Revolution; the other half were, like Deng Xiaoping, the Cultural Revolution's victims. The balance, however, quickly shifted in favour of the latter group.

Economic policy changes. In the late fall of 1976, the CCP leadership tried to bring some order to the country through a series of national conferences. They moved quickly to appeal to workers' interests by reinstating wage bonuses. The economy had stagnated in 1976 largely because of political turmoil, and Mao's successors were anxious to start things moving again. Despite some uncertainty, Deng was rehabilitated and formally brought back into his previous offices in the summer of 1977.

Lacking detailed information on the economy, the leaders adopted an overly ambitious 10-year plan in early 1978 and used the government's resources to the limit throughout that year to increase investment and achieve rapid economic growth. Much of that growth consisted of reactivating capacity that had lain idle due to political disruption. Future growth would be harder to achieve, and long-term trends in such matters as capital–output ratios made it clear that the old strategies would be ineffective.

Resumption of foreign trade

One of the changes of 1978 was China's turn toward participation in the international economy. While in the 1970s there had been a resumption of the foreign trade that had been largely halted in the late 1960s, along with more active and Western-oriented diplomatic initiatives, the changes during and after 1978 were fundamental. China's leaders became convinced that large amounts of capital could be acquired from abroad to speed up the country's modernization, a change in attitude that elicited an almost frenetic response from foreign bankers and entrepreneurs.

These several strands came together in late 1978 at a major meeting of the CCP leadership, when China formally agreed to establish full diplomatic relations with the United States. China's leaders also formally adopted the Four Modernizations as the country's highest priority, with all other tasks to be subordinated to that of economic development. This set of priorities differed so fundamentally from those pursued during the Cultural Revolution that the implications for future policy and for the interests of various sectors of the population were profound.

The opening of China's economy to the outside world proceeded apace. In the late 1970s the country adopted a joint-venture law, and it subsequently enacted other laws (for instance, on patents) to create an attractive environment for foreign capital. An experiment with "special economic zones" along the southern coast in the late 1970s led in 1984 to a decision to open 14 cities to more intense engagement with the international economy. The idea was to move toward opening ever larger sections of the country to foreign trade and investment.

In the domestic economy, experiments were undertaken in finance, banking, planning, urban economic management, and rural policy. Of these, by far the most important were the series of measures taken toward the nearly 80 percent of the population that lived in the countryside. Prices paid for farm products were sharply increased in 1979, thus pumping additional resources into the agricultural sector. The collective farming system was gradually dismantled in favour of a return to family farming. At first, families were allowed to contract for the use of collective land for a limited period of time. Subsequently, the period of those contracts was extended.

Peasants were also allowed far greater choice in what crops to plant. Many peasants even abandoned farming altogether in favour of establishing small-scale industries, transport companies, and other services. Thus, rural patterns of work, land leasing, and wealth changed markedly after 1978. Exceptionally good weather during the early 1980s contributed to record harvests.

The reforms in the urban economy had more mixed results, largely because the economic system in the cities was so much more complex. Those reforms sought to provide material incentives for greater efficiency and to increase the use of market forces in the allocation of resources. Problems arose because of the relatively irrational price system, continuing managerial timidity, and the unwillingness of government officials to give up their power over economic decisions, among other difficulties. In the urban as well as the rural economy, the reformers tackled some of the fundamental building blocks of the Soviet system that had been imported during the 1950s.

Reforms have continued in the rural and urban areas. Rural producers have been given more freedom to decide how to use their earnings, whether for agricultural or other economic activities. Private entrepreneurship in the cities and the rationalization, privatization, and, in some cases, dismantling of state-owned enterprises has gained speed. At the same time, the central government is moderating the pace of change—primarily to avoid increases in social unrest resulting from rising unemployment—and constructing a social safety net for those who lose their jobs.

Political policy changes. The reformers led by Deng Xiaoping tried after 1978 to reduce political coercion in Chinese society. Millions of victims of past political campaigns were released from labour camps, and bad "class labels" were removed from those stigmatized by them. This improved the career and social opportunities of millions of former political pariahs. Moreover, the range of things considered political was narrowed, so that style of dress and grooming and preferences in music and hobbies were no longer considered of political significance. More importantly, policy criticisms no longer triggered political retaliation. Overall, the role of the Public Security (police) forces was cut back substantially.

Rehabilitation of CCP cadres

The reformers also tried to make preparations for their own political succession. This involved first the rehabilitation of cadres who had been purged during the Cultural Revolution. These cadres in many cases were old and no longer fully able to meet the demands being made on them, and they were encouraged to retire. Younger, better-educated people committed to reform were then brought into prominent positions. Deng proved masterful at maintaining a viable coalition among the diverse forces at the top. By the end of 1981 he had succeeded in nudging Hua Guofeng and others of the more rigid Maoists out of high-level positions. Although he refused to take the top position for himself, Deng saw his supporters become premier and general secretary of the CCP, and he worked hard to try to consolidate their hold on power.

During early 1982 the CCP leadership made a concerted attempt to restructure the leading bodies in both the government and the party, and much reorganization took place, with the appointment of many new officials. This general effort continued, with the focus increasingly on the bloated military establishment, but progress slowed considerably after the initial burst of organizational reformism.

Throughout 1982–85 the CCP carried out a "rectification" campaign to restore morals to its membership and weed out those who did not support reform. This campaign highlighted the difficulties in maintaining discipline and limiting corruption during rapid change, when materialistic values were being officially propagated.

By the mid-1980s China was in transition, with core elements of the previous system called into question while the ultimate balance that would be struck remained unclear even to the top participants. The reform movement began to sour in 1985. Financial decentralization and the two-price system combined with other factors to produce inflation and encourage corruption. China's population, increasingly exposed to foreign ideas and standards of living, put pressure on the government to speed the rate of change within the country.

These forces produced open unrest in the country in late 1986 and again on a larger scale in the spring of 1989. By 1989 popular disaffection with the CCP and the government had become widespread. Students—eventually joined by

others—took to the streets in dozens of cities from April to June to demand greater freedom and other changes. Government leaders, after initial hesitation, used the army to suppress this unrest in early June, with substantial loss of life. China's elderly revolutionaries then reverted to more conservative economic, political, and cultural policies to reestablish firm control. In 1992, however, Deng Xiaoping publicly criticized what he called the country's continuing "leftism" and sought to renew the efforts at economic reform. Economic growth had been remarkable in South China, which had the highest concentration of private-sector enterprises. Since the mid-1990s, the CCP has worked to drastically accelerate market reform in banking, taxes, trade, and investments. These reforms have continued apace, and the party has attempted to increase public support by conducting energetic anticorruption campaigns, relying in part on high-profile prosecutions and occasional executions of high-level officials accused of corruption.

Economic reform

Educational and cultural policy changes. In education, the reformers gave priority to training technical, scientific, and scholarly talent to world-class standards. This involved the re-creation of a selective, elitist educational system, with admission based on competitive academic examination. Graduate study programs were introduced, and thousands of Chinese were sent abroad for advanced study. Foreign scholars were used to help upgrade the educational system. Ironically, the value the reformers attached to making money had the unintended consequence of encouraging many brilliant people to forgo intellectual careers in favour of more lucrative undertakings. The range of cultural fare available was broadened, and new limits were constantly tested. Few groups had suffered so bitterly as China's writers and artists, and policies since the 1980s have reflected the ongoing battle between cultural liberals and more orthodox officials.

International affairs. China's foreign policy since 1978 generally has reflected the country's preoccupation with domestic economic development and its desire to promote a peaceful and stable environment in which to achieve these domestic goals. Except for its disagreement with Vietnam over that country's invasion of Cambodia in 1978, China has by and large avoided disputes and encouraged the peaceful evolution of events in Asia. China adopted a policy of "one country, two systems" in order to provide a framework for the successful negotiation with Great Britain of the return of Hong Kong and adjacent territories in 1997; these were given special administrative status. Furthermore, China became an advocate of arms control and assumed a more constructive, less combative stance in many international organizations.

The bloody suppression of demonstrations in 1989 set back China's foreign relations. The United States, the European Community (European Union since 1993), and Japan imposed sanctions, although by 1992 China had largely regained its international standing with all but the United States. But by the mid-1990s both sides had taken steps toward improved relations, and China retained its most-favoured-nation status in U.S. trade. The collapse of communism in eastern Europe beginning in mid-1989 and the subsequent disintegration of the Soviet Union deeply disturbed China's leaders. While hard-liners used these developments to warn of the dangers of reform, Deng Xiaoping continued to advocate reform until his death in 1997. With the adoption by the U.S. Congress of most-favored-nation status for China, the country took an important step toward further integration into the global economy. (K.G.L.)

NORTHEAST CHINA

Heilungkiang

Heilungkiang (Hei-lung-chiang in Wade–Giles romanization, Heilongjiang in Pinyin), the northernmost province of China's Northeast region, is bounded on the north and east by Russia along the Amur River (Hei-lung Chiang) and the Ussuri (Wu-su-li) River, on the south by the Chinese province of Kirin, and on the west by the Inner Mongolia Autonomous Region of China. The province has an area of about 179,000 square miles (463,300 square kilometres). The capital is Harbin. Heilungkiang occupies about three-fifths of the area of the three Northeast provinces that formerly made up Manchuria and has more than one-third of the region's population. The province's name is derived from the Chinese name for the Amur.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The province of Heilungkiang occupies about half of the huge Manchurian Plain, surrounded on three sides by old mountain ranges of medium elevation. Its central part is the Sungari–Nen river plain, delimited by the Greater Khingan (Ta-hsing-an) Range of Inner Mongolia on the west, the Lesser Khingan (Hsiao-hsing-an) Range on the north, and the Chang-kuang-ts'ai and Lao-yeh ranges (both partially located in Kirin) on the east. Elevations in Heilungkiang generally are low, exceeding 3,300 feet (1,000 metres) only in the southeastern and northwestern mountains and in isolated peaks in the Lesser Khingan Range.

Mountain ranges

The mountains of the northwest—the northern fringe of the Greater Khingan Range—are composed mainly of igneous rocks resistant to erosion and weathering. The structure of the Lesser Khingan Range is more complex. Its northern part is composed of granite, volcanic basalt, and other metamorphic rocks. The average elevation is about 2,300 feet; the granite peaks near I-ch'un rise to about 3,770 feet. The western slope facing the Nen (Nonni) River is gentle, while the eastern slope is steep. The southern end of the Lesser Khingan is composed of archlike, folded, stratified rock. A few of the highest peaks reach over 3,300 feet, but the hills are generally lower. The valleys of the foreland are often broad and smooth, dotted with swamps. The rolling Sungari–Nen plain, at an elevation of 490 to 600 feet, has many bogs and swamps. In contrast, sand dunes occur in the drier western part of the plain.

Drainage. The Amur is the longest stream in the province. Its upper and middle sections serve as the international boundary for a distance of 1,180 miles (1,900 kilometres). Ice begins forming on the Amur in mid-October, and it becomes icebound by mid-November; the river is not completely ice-free until May. The Amur's chief tributary, the Sungari (Sung-hua) River, is the main waterway of the province, however. Most of the Sungari drainage system lies within the province. The Ussuri River forms the Sino-Russian boundary on the east, flowing along a longitudinal valley between mountains. It is a broad, slow-moving river and has a tributary linking it with Lake Khanka (Hsing-k'ai Hu), the largest freshwater lake in East Asia. Only one-quarter of the lake, which is on the Sino-Russian border, is in China.

Soils. The soils in the province are complex. In the Lesser Khingan mountains, soils differ with altitude. Black soils (chernozems) are prevalent in the foothills, and mountain brown forest soils higher up. Still higher the cold, wet soils are podzolized; *i.e.,* the soluble salts and organic matter are leached out of the topsoil and deposited in an underlying subsoil. Such soils are of low fertility, and their cultivation causes erosion. The humus-rich, highly fertile black soils that cover one-fourth of the province are found in the Sungari–Nen river plain. Its eastern part has the best soils, yielding crops for years without fertilization. The chernozem lands form the main agricultural region of the province.

Climate. The province has severe winters, lasting five- to eight months. Summer is short but coincides with the

rainy season, making it possible to raise temperate crops in most areas. There are considerable regional differences in climate. The northwest has a cold, wet, temperate climate with very cold winters; summer thaw is only superficial.

Temperatures

Hu-ma, on the Amur River, has a mean temperature of −18° F (−28° C) in January. The July mean temperature is 75° F (24° C). There are only four months with mean temperatures over 50° F (10° C).

A temperate, wet climate prevails in the eastern section, in the drainage basin of the Ussuri River and the lower Sungari River. In the central core of the province the climate is temperate, with a deficiency of precipitation and very severe winters. Nen-chiang, in the northern Manchurian Plain, has mean temperatures of −16° F (−27° C) in January and 70° F (21° C) in July. The mean annual precipitation is 20 inches (510 millimetres), most of which falls from June to September.

The southern part of the province is also very cold in winter but enjoys a warmer summer and a longer growing period. Harbin has mean temperatures of −2° F (−19° C) in January and 73° F (23° C) in July. Its mean annual precipitation is 21 inches.

Plant and animal life. The original vegetation of the province was forest-prairie, but it has been largely destroyed by cultivation; the remaining trees are predominantly poplars. There are many species of herbaceous plants, pasture grasses, and sorghums. The central part of the plain was originally prairie-steppe; the western part of the plain is a drier steppe.

The province's fauna is predominantly that of the Manchurian Plain, which constitutes the larger part of Heilungkiang. It has a predominance of temperate mixed-forest animals, with a significant admixture of elements of the Eurasian taiga. Among the district's representative animals are the Manchurian hare, the eastern field vole, the rat hamster, the Far Eastern finches, the buteo hawk, the needle-footed owl, and some species of flycatchers. Insects include the duckling beetle, the ground beetle, and the bumblebee. The region's fauna yield valuable fur and pelts, including the sable, panther, fox, chipmunk, Manchurian hare, and light-coloured polecat.

The northwestern mountains have fauna more akin to that of the boreal forests of Europe and Siberia. The more common wildlife includes the brown bear, squirrels, chipmunks, some forest voles, the kolinsky (or Asiatic) mink, the wood hen, the crossbill, and the Siberian frog. Among the insects may be mentioned long-horned beetles, the ground beetle, and the Siberian silkworm. During the long, cold winter the birds migrate to warmer regions as far south as the Malay Peninsula.

The people. The population is predominantly Han (Chinese), but there are other significant ethnic groups, notably the Manchu, Koreans, Hui (Chinese Muslims), and Mongols (including Daghur Mongols). Other, smaller groups include the O-lun-ch'un, Evenk (E-wen-k'o), and Hochen (Nanai). After the establishment of the Communist government, an autonomous county and several autonomous villages were created in areas inhabited by ethnic minorities.

The Manchu

The Manchu form the largest minority group and are distributed largely in the southern part of the province. They have been culturally assimilated by the Han majority. Most of them farm; their way of life is similar to that of the Han, and intermarriage is common, especially among the former nobility and the educated.

Korean immigration started in the mid-19th century. After the Japanese annexation of their country in 1910, a large number of Koreans emigrated to Heilungkiang and Kirin provinces, where they converted large areas of swampy wasteland into rice paddies. They live mostly in southeastern Heilungkiang, where many autonomous Korean villages have been established. The Hui live and work mostly in the bigger cities as merchants, handicraftsmen, and proprietors of beef and mutton restaurants. Those in An-ta and Chao-tung raise goats and dairy cattle. Mongols live in the drier western part of the province, where they engage in farming and animal husbandry. Many of them live in the Mongolian autonomous county in the western part of the province.

The Daghur (Ta-wo-erh) Mongols live mostly in the upper Nen River valley, on the eastern foreland of the Greater Khingan Range. They are believed to have come from the north side of the Amur River during the 15th and 16th centuries. Hunters originally, they became the earliest farmers of Heilungkiang. Probably the O-lun-ch'un also came from north of the Amur River, later to settle in the Khingan ranges as farmers and hunters. They had domesticated the deer and were once known as the "deer riders." The O-lun-ch'un were among the earliest inhabitants of the upper and middle Amur. The Evenk tribespeople moved into the province in the 1st century AD. They are believed to be descendants of the Su-shen (Evenk) tribes of the Chou dynasty. They now live in the Amur River valley, near Ai-hui. Originally hunters, they have learned to farm since 1949.

Russians entered the province at the end of the 19th and in the early 20th centuries. A great number of émigrés arrived after the Bolshevik Revolution. Some of these stayed and became Chinese citizens, many of them women who married Chinese. The few remaining Russians in the province live mostly in Harbin.

The economy. Despite the great mineral and agricultural potential of Heilungkiang, the provincial economy was relatively underdeveloped until the mid-20th century. The process of economic growth began in the 1920s and '30s with the arrival of railroads and concomitant mineral exploitation. By the 1950s the provincial industrial output per capita was well above the national average.

Agriculture and forestry. Since 1949 large tracts of low-lying alluvial land have been reclaimed between the Sungari and Ussuri rivers. Large-scale state farms were established there, and millions of acres were brought under cultivation to produce sugar beets, soybeans, corn (maize), and wheat. Although cultivation in the region is highly mechanized, there is relatively little use of irrigation or chemical fertilizers. Heilungkiang is one of China's major grazing areas, its plains supporting large herds of livestock. The province also is one of China's largest producers of raw timber.

Industry. Much of Heilungkiang's industry is based on the exploitation of mineral resources. During the 1950s

Jim Brandenburg

Sawing timber at a lumber camp near I-ch'un in the forested region of the Lesser Khingan Range, Heilungkiang Province.

emphasis was placed on the development of coal mining and thermal and hydroelectric power generation. The Ta-ch'ing oil field began operation in 1960 and subsequently developed into China's major inland field. Heilungkiang is the nation's largest producer of crude oil, accounting for almost half of China's output. Much of the oil is used in Heilungkiang's petrochemical industry.

The Ta-ch'ing oil field

The city of Chia-mu-ssu, on the Sungari River, was built up as a military and air base during the Japanese occupation (1931–45). Four strategic railways were completed, linking the city with T'u-men, on the North Korean border; Sui-hua, to the west; Ho-kang, to the north; and Shuang-ya-shan, to the east. With the rapid industrial development under the Chinese Communists, the city began to produce machinery and electrical and telecommunication equipment. The Chia-mu-ssu paper mill is one of the largest in China, producing both for domestic needs and for export, and there is also a food-processing industry.

Another burgeoning industrial city is Shuang-ya-shan, east of Chia-mu-ssu. Its development began after World War II. The city has a number of large plants for metal and food processing and for the production of lumber and construction materials. Tsitsihar (Ch'i-ch'i-ha-erh), the second largest city and former capital of the province, also grew phenomenally in the 1950s.

Harbin, the largest city and capital of the province, grew in 1898 as a construction base for the Chinese Eastern Railway across northern Manchuria. It soon became the major transportation hub and communications centre of northern Manchuria, with direct rail links to the Russian railroad network and to the Sea of Japan; through the South Manchurian Railway, it is linked with the Chinese and Korean rail networks and the Pacific. Numerous handicraft industries and small oil-pressing and flour mills are located there. By the 1950s the Harbin area had become one of China's primary industrial development centres, with an emphasis on heavy industry. It produces a variety of machinery and has chemical and fertilizer industries. The city is also a food-processing centre, as well as a producer of textiles, lumber, and construction materials.

Transportation. The province's main north–south rail line extends from Chia-mu-ssu, through Harbin, to Lü-ta (Dairen) in Liaoning Province, while the main east–west line runs from Mu-tan-chiang, through Harbin, to Manchou-li in Inner Mongolia. There are also secondary lines. Inland waterways are not important, except for the Sungari River during the ice-free months. Most freight is carried by railroads or highway.

Administration and social conditions. The boundaries of Heilungkiang fluctuated during the early 20th century. From 1950 to 1954 the province was under the jurisdiction of the Northeast Military Administrative Commission based in Shen-yang. In 1954 Heilungkiang was placed directly under the central government, and its boundaries were expanded eastward across the Sungari River to the Ussuri River frontier with the Soviet Union. Also during the 1950s, territory in western Heilungkiang that included the Greater Khingan Range was transferred to Inner Mongolia; this region again became part of Heilungkiang in 1969 but was restored to Inner Mongolia in 1979. The province (*sheng*) is divided administratively into 14 prefectures (*ti-ch'ü*) and 11 prefecture-level municipalities (*shih*). These districts are further divided into counties (*hsien*) and county-level municipalities (*shih*).

Education

Harbin is an important educational centre, especially in engineering and applied science. The Harbin Institute of Technology was founded in 1920 to train technical personnel for the Chinese Eastern Railway. It offers specialized programs in departments of engineering and technology as well as a graduate school. Heilungkiang has numerous postsecondary educational institutions and a large corps of scientists and technicians. Almost all school-age children are enrolled in schools, and the province's literacy rate is substantially above the national norm.

HISTORY

The prehistoric population of the region appears to have consisted of people who bred pigs and horses; known as Tungids, they occupied much of northeastern Asia. Stone Age fishermen, the Sibirids and Ainoids, lived along the rivers and coast.

Heilungkiang was long sparsely inhabited by hunters and fishermen who used canoes, dogsleds, skis, and reindeer as transport. The town of San-hsing (now I-lan) was the home in the early 15th century AD of the ancestors of Nurhachi, the Manchu tribal leader who rose to power in the late 1500s through struggles with rival tribes and alliances with Manchu-related groups. Nurhachi's son, Prince Dorgon, ruled as regent during the reign of the first Ch'ing, or Manchu, emperor of China, the Shun-chih emperor.

During the 17th century the region became a zone of competition between Russia and China. Bands of musket-bearing Cossacks had been exacting tribute in furs from the tribes living along the Amur River, and in 1650 a Russian fort was built at Albazino on the river's north bank. The Ch'ing dynasty appointed a military governor to administer the region in 1683. The fort at Albazino was destroyed, and Russian retaliation was firmly opposed. By the Treaty of Nerchinsk (1689), the Russian government recognized Chinese suzerainty over the lands lying on both sides of the Amur River.

The tribes of Heilungkiang failed to recover their numerical strength after the Manchu rise to power and even after Manchu culture declined, despite the intentions of Ch'ing emperors to maintain their native language and way of life. Although large areas of Heilungkiang are fertile, agricultural development proceeded there very slowly because of the reluctance of Ch'ing rulers to allow the establishment of farms in their traditionally pastoral homeland. The region remained sparsely settled because access was difficult before the building of the railroads, and it was therefore highly vulnerable to Russian and Japanese expansion during the 19th century.

In 1858 Russia annexed the region north of the Amur River to its mouth and two years later the region east of the Ussuri River to the Sea of Japan, including the seaport of Vladivostok and the Ussuri–Amur river port of Khabarovsk. The Russians occupied Heilungkiang from 1900 to 1905 and maintained their domination—despite their defeat by Japan in the Far East in 1904–05—through control of the strategic Chinese Eastern Railway, running through the region from west to east. After the Russian Revolution of 1917 the Bolsheviks renounced special privileges in northern Manchuria as a friendly gesture toward China. Heilungkiang remained under Chinese control until Japan invaded Manchuria in September 1931. It then became a part of the Japanese puppet state of Manchukuo (1932–45). On Aug. 15, 1945, just before Japan's surrender, Soviet troops entered Manchuria, but they evacuated it later to make way for Chinese Communist troops. After the Sino-Soviet rift in 1960, there were several clashes along the international border. (F.Hu./V.C.F./Ed.)

Russian occupation

Kirin

A province of the Northeast region of China, Kirin (Chilin in Wade–Giles romanization, Jilin in Pinyin) borders Russia to the east, North Korea to the southeast, the Chinese provinces of Liaoning to the south and Heilungkiang to the north, and the Inner Mongolia Autonomous Region to the west. It has an area of about 72,200 square miles (187,000 square kilometres). The capital (since 1954) of the province is Ch'ang-ch'un.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The province may be divided into three parts: the eastern mountains, the western plains, and a transitional zone of rolling hills between them. Elevation decreases from the highlands in the southeast toward the Manchurian Plain in the northwestern part of the province. The mountains of eastern Kirin take the form of parallel ranges with the Cathaysian or Sinian trend and are separated by broad valleys. The most famous of the ranges is the Ch'ang-pai Mountains close to the Korean border. One of its snow-covered summits is 9,000 feet (2,744 metres) above sea level—the highest peak in northeastern China. The summit is formed by a volcanic crater occupied by a lake. The range is the source of three

important rivers: the Sungari, the Yalu, and the Tumen. The middle section of the Manchurian Plain forms the northwestern part of the province and constitutes three-eighths of its area. It has a rolling topography, with an average elevation of about 650 feet above sea level.

Drainage. The Yalu and Tumen rivers flow in opposite directions along the Sino-Korean border. The Yalu runs southwest to Korea Bay, the Tumen down the Ch'ang-pai range northeastward to the Sea of Japan. The two rivers are of great strategic importance, guarding the land approaches to northeastern China from the Korean peninsula. The Sungari River is the major stream of Kirin. It flows for almost 500 miles (800 kilometres) within the province, draining an area of more than 30,000 square miles. Its upper course runs northwest in a series of rapids through heavily forested mountains before it enters the Sungari Reservoir, a man-made lake. Emerging from the reservoir, the Sungari flows past Chi-lin (Kirin city), situated at the head of navigation of the Sungari River and at the geographical centre of the province. The river enters the Manchurian Plain and is shortly afterward joined by its chief tributary, the Nen River, which is in fact larger than the Sungari. It then turns sharply east to run along the provincial boundary for a short distance before it leaves Kirin Province.

Soils. There are two main types of soil in the province: podzols in the eastern mountainous region and black earth in the western plains. The podzols occur in several forms and are of both high and low fertility. Central and western Kirin are the areas of the black earths of the Manchurian Plain. Of high fertility and containing a high percentage of organic matter, they form good arable land. The young alluvial soils along the Sungari and its tributaries also provide excellent land for cultivation. In western Kirin are saline soils, alkaline soils, and high-alkaline soils of low agricultural value.

Temperature and precipitation

Climate. Kirin Province forms a transitional climatic zone between the northern and southern portions of China's Northeast. The winter is cold and long, and rivers are frozen for about five months; the ice on the Sungari is thick enough to support mule carts. Ch'ang-ch'un, near the centre of China's Northeast, has mean temperatures of 2° F (−17° C) for January and 74° F (23° C) for July. It has a mean annual precipitation of about 25 inches (630 millimetres), more than 80 percent of it during the five warm months from May to September. Precipitation increases southeastward to more than 40 inches in the Ch'ang-pai Mountains area but decreases westward; the Manchurian Plain receives only 16 inches.

Plant and animal life. The natural vegetation is prairie grass in the western plains and mixed conifer and broad-leaved deciduous forest in the eastern mountainous area. The vegetation in the eastern mountains includes tree species such as the Japanese red pine, Manchurian ash, fish-scale pine, larch, birch, oak, willow, elm, and the Manchurian walnut. In the deep mountain interior, virgin forest has been preserved. Tree types are distributed in distinct belts depending mainly on altitude: between 800 feet and 1,600 feet of elevation is the deciduous broad-leaved belt, mainly mountain willow and thumb; between 1,600 feet and 3,000 feet is found mixed coniferous and broad-leaved forest; between 3,000 feet and 5,900 feet occurs coniferous forest; and from 5,900 feet to 6,900 feet is found mountain birch.

Tree types

Many valuable wild animals and medicinal plants are found in the forested mountain areas. The Manchurian hare, valued for its fur, and some species of rodent such as the rat hamster and the eastern field vole are believed to be peculiar to the Manchurian forest. Among birds, finches, the buteo hawk, the needle-footed owl, the black and white barrier, and certain species of flycatcher are typical. Among semiaquatic animals, the lungless newts are notable. Certain species of snakes, such as the Schrenk racer, found in the inhabited areas of the Northeast and Korea, live in a semidomesticated state and are used to eliminate harmful rodents in orchards and gardens. The European wild boar, the common hedgehog, the Asian red deer, the harvest mouse, and the field mouse are among the more common Eurasian species. Valuable pelts include fox, chipmunk, the light-coloured polecat, the Manchurian hare, and the sable. The sable population, however, has become very small.

The people. Han (Chinese) predominate throughout the province, except in an autonomous prefecture for Koreans that is contiguous with North Korea. Most of the Manchu live in the central part of the province, in Chi-lin Municipality and T'ung-hua Prefecture. A few Hui (Chinese Muslims) are distributed in the cities and towns of the province, and some Mongolians are to be found in the Pai-ch'eng area in northwestern Kirin.

The economy. *Agriculture and forestry.* Kirin is a significant producer of soybeans, corn (maize), sugar beets, and oil-bearing crops, and its farmers earn an income well above the national average. This is in part due to the high land–labour ratio but also to the relatively high yields produced with the use of agricultural machinery and irrigation. In the eastern uplands, rice and millet are the staple produce of the Korean population.

In the upper Sungari Basin, timber production for construction and milling is a major economic activity. In the eastern sections of the province, much of the forestry activity centres on pulp and paper production.

Mining and power resources. The major minerals of the province include coal, iron ore, copper, zinc, and gold. Coal is found in the southeast, near the Yalu River border with North Korea. Many smaller local mines also supply provincial needs. The major hydroelectric power installation, the Feng-man station on the Sungari River southeast of Chi-lin, was built by the Japanese during World War II and rebuilt by the Soviets in the 1950s.

Industry. Kirin is relatively highly industrialized and is a major producer of chemicals, machine tools, power, and forest products. Originally a lumbering and food-processing centre, the province acquired a heavy industrial base during the Japanese occupation of 1931–45. It was a major beneficiary of Soviet investment in the mid-1950s, acquiring an automotive industry and metals and fabrication industries. In the 1960s the Feng-man hydroelectric power station made possible the development of chemical and ferro-alloy industries. Most industry is concentrated in the two largest cities in the province—Ch'ang-ch'un and Chi-lin.

Transportation. Most of the municipalities and counties in the province have direct access to a rail line. The Sungari is the main artery of the inland navigation network. Its tributary the Hui-fa River and the Tumen River are

Xinhua News Agency

The Feng-man hydroelectric power station on the Sungari River in Kirin Province.

both navigable by wooden vessels. The Yalu is navigable by steamers up to Yü-shu-lin-tzu and by wooden vessels above that point. The highway network has regional centres at Ch'ang-ch'un, Chi-lin, Yen-chi, and T'ung-hua.

Administration and social conditions. Kirin was one of the Manchurian provinces until the Communists subordinated the region to the Northeast Military Administrative Commission in 1950. In 1954 the province was enlarged through the addition of a strip of territory annexed from northern Liaoning, including the cities of Ssu-p'ing, Liao-yüan, and T'ung-hua and a portion of Heilungkiang's steppe district near Pai-ch'eng. After 1954, with the abolition of the regional government, the province came under direct administration of the central government. Kirin is divided into two prefectures (*ti'ch'ü*), one autonomous prefecture (*tzu-chih-chou*), and five prefecture-level municipalities (*shih*). The province is further divided into counties, some of which are under the control of the municipalities or are autonomous counties established for minority nationalities.

Education

Kirin's educational facilities are well developed, with more than 30 universities and other post-secondary institutions. Overall literacy rates are significantly higher than the national average, as is the proportion of the population with at least a primary level education. Medical services are provided by hospitals and clinics staffed by medical workers, including doctors and practitioners of Chinese medicine.

HISTORY

In early modern times the Kirin region was inhabited by groups of steppe and forest dwellers and was at times loosely united politically by leaders who presented tribute of furs, ginseng, and pearls at the court of the Ming emperors of China. In the late 16th century the Hurka tribe dominated the region before being defeated by the Manchu leader Nurhachi. After the establishment of the Ch'ing, or Manchu, dynasty in 1644, the region was at first directly administered by a military governor posted in the town of Chi-lin, and the region was thereafter referred to as Kirin.

Despite the Ch'ing government policy of discouraging agricultural settlement in the Manchu homeland, large numbers of settlers from North China established farms in the region during the 18th century, a period of rapid population expansion in China proper. In 1799 the transition to an agricultural economy was officially recognized with the establishment of a prefectural government at Ch'ang-ch'un to administer the new settlements. In the late 19th century, economic development accelerated in Kirin with the building of railways and industries processing agricultural products. This development encouraged a new influx of Chinese settlers and led to conflict between Russia and Japan over economic interests in the area.

Kirin was created a province in 1907, near the end of the Ch'ing dynasty, and was occupied by the Japanese Army in 1931, becoming a part of the puppet state of Manchukuo (1932–45). Just before Japan's surrender to the Allies on Aug. 15, 1945, Soviet forces entered the region, dismantled key industrial installations, and removed them to the Soviet Union. Following the withdrawal of Soviet troops, Chinese Nationalists moved in, but by 1948 they had been driven out by Chinese Communist forces.

(F.A.L./V.C.F.)

Liaoning

Liaoning (Liao-ning in Wade–Giles romanization, Liaoning in Pinyin) is the southernmost of the three Chinese provinces of the Northeast region (formerly called Manchuria). With an area of 56,300 square miles (145,700 square kilometres), Liaoning is bounded on the northeast by the province of Kirin, on the east by North Korea, on the south by the Yellow Sea, on the southwest by the province of Hopeh, and on the northwest by the Inner Mongolia Autonomous Region. The provincial capital is Shen-yang (formerly Mukden).

The area, a region of early Chinese settlement in the Northeast, was known as Sheng-ching in Ch'ing, or Manchu, times (1644–1911/12). The area was redefined in 1903 and named Fengtien; in 1928 the boundaries were altered and it was renamed Liaoning. From 1947 to 1954 the territory was divided into a western province, Liaosi, and an eastern province, Liaotung. In 1954, however, a northern zone was detached and it was reestablished as a single province. It achieved its present form in 1956, when the former province of Jehol was partitioned and a portion added to Liaoning. Liaoning, Liaosi, and Liaotung all take their names from the Liao River. Precedents for the names go back to Han times.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Liaoning consists essentially of a central lowland, with Shen-yang at its centre, flanked by mountain masses to east and west. A southward extension of the eastern highlands forms the Liaotung Peninsula. There are four main topographical regions: the central plains, the Liaotung Peninsula, the western highlands, and the eastern mountain zone.

The four main regions. The central plains are the most important area in the province. Structurally, the depression that it occupies is continuous with that of the North China Plain, but, topographically, the Liaoning plains are erosional rather than depositional in character. The relief of the plain is undulating but low, and natural drainage is inadequate in many places, creating swamps, some of which have been redrained. Most of the landscape of the central plains consists of cultivated fields. Undeveloped areas include swamps and sand formations. The soils of the middle of the Liao lowland are of the calcareous alluvial type; those of the peripheries to east and west, of brown-forest types; those of the northern peripheries, red earths. The swamps have gley soils (having a sticky layer of clay under the waterlogged surface). Wild animals are scarce, apart from rodents. Locusts are the most destructive pest.

The Liaotung Peninsula is a rugged, mountainous area with a rocky coast. The usual height of the country is 1,000 to 1,500 feet (300 to 450 metres) above sea level. The rock types are very mixed, a fact that tends to create a complex and varied topography. Structurally, the peninsula represents a part of the same fold system as Shantung. The coastline is experiencing submergence. The soils of the peninsula, like the rock types and the topography, are very mixed and varied. Most of the best soils are of brown-forest type or of red or yellow loess (an unstratified wind-borne loamy deposit). There has been serious soil erosion, and skeletal soils occur on the steeper slopes. The natural vegetation is not well preserved because of the extent of cultivation and settlement. The forests that remain, mostly on the eastern sides of the hills, contain birch, lime, elm, and pine, together with typical Manchurian trees—oak, apple, and ash. On the western sides, trees are scarce. Wild animal life is now meagre, being almost limited to rodents.

Western Liaoning, fringing the northern shore of Liaotung Bay between Shan-hai-kuan and Chin-chou, is predominantly a highland area. These highlands comprise the broken and eroded fringe of the Mongolian Plateau. They rise in Liaoning to general heights of about 1,500 feet. Toward the sea the mountains have been intensely eroded by fast-flowing rivers, so that a complex mass of valleys and ridges has been formed. Vegetation is very mixed and includes oaks, birches, pines, limes, and spruces. In former times, especially between 1911 and 1948, there was much indiscriminate cutting and thinning of the forests, so that many areas now have scattered woodland where formerly thick forest stood. The animal life of the western highlands is impoverished by the extent of both forest clearance and human settlement, but it includes the wolf, fox, marmot, and some kinds of deer.

The eastern mountain zone lies to the east of Shen-yang. The least developed part of the province, it consists of a complex mountain mass, extending northward into Kirin Province, with elevations averaging about 1,500 feet. Natural vegetation is predominantly a mixed coniferous and broad-leaved forest.

Climate. Temperature extremes and precipitation amounts vary with proximity to the coast. At Lü-ta (Dairen), at the southern tip of the Liaotung Peninsula,

the January mean temperature is 23° F (−5° C) and that for July is 74° F (23° C); for Shen-yang, in central Liaoning, the respective mean temperatures are 10° F (−12° C) and 77° F (25° C). At Lü-ta there are about 200 frost-free days, while at Shen-yang there are between 160 and 180 frost-free days per year. Rainfall in Liaoning as a whole diminishes consistently from southeast to northwest. Average annual precipitation is about 29 inches (740 millimetres), three-quarters of it falling in the months of June, July, August, and September, and almost none during December, January, and February. The summer rainfall is often torrential, but everywhere the scarcity of spring precipitation tends to leave crops short of water.

Ethnic composition and distribution

The people. In Liaoning almost all of the population is recorded as Han (Chinese). The bulk of the national minority population is Manchu, located mainly in the Liao Valley and around Shen-yang, in the southeast around Tan-tung, and in the southwest around Chin-chou. The second significant minority is that of the Mongols, who are located toward the frontier of the Inner Mongolia Autonomous Region to the west. Broadly speaking, the Hui (Chinese Muslim) minority follows the Manchu in its distribution. There are two autonomous counties representing the Mongolian minority nationality. One is centred on the coal town of Fu-hsin, and the other is in the southwest. A small Korean minority is located near the Korean frontier.

Apart from the registered minority populations, many of the Han people of modern Liaoning have origins that are wholly or partly non-Han, usually Mongol or Manchu. Many of them are now totally assimilated into the Chinese sector of the population, in language and custom as well as in the adoption of contemporary Han life-styles.

All of the large cities are industrial, and some experienced spectacular growth in the 1950s. They include the following: Shen-yang (earlier called Mukden, Feng-t'ien, or Sheng-ching); Lü-ta (comprises Lu-shun, formerly called Port Arthur, and Dairen); Fu-shun; and An-shan.

Industrial importance

The economy. The economy of Liaoning is by far the strongest in the Northeast and is one of the strongest provincial economies in China. Liaoning is one of the country's principal industrial provinces. One reason for the high level of development in Liaoning is the level of capitalization—very high by Chinese standards—which is based both on investments made under the government since 1949 and on important foreign investments made between 1896 and 1945, mainly by the Japanese.

Resources. Liaoning Province is rich in mineral resources, especially iron ore and coal. Most of the iron ores of Liaoning are concentrated in a triangular area to the south of Shen-yang. These ores are generally easy to mine but are of relatively poor quality; ores of better quality occur in the northeastern part of the province. Coal is more widespread, and its distribution partly overlaps that of iron. Coal is exploited in three main areas to the north, east and southeast, and west of Shen-yang. Fu-shun, east of Shen-yang, and Fu-hsin, to the west, have two of the most important collieries in China. Both were exploited under the Japanese but have been expanded since the Communists came to power. Apart from its use as fuel and in smelting, coal is used in Liaoning to produce synthetic petroleum. Petroleum is also produced from oil shale, which occurs in the Fu-shun area and in western Liaoning, generally overlying coal seams. The Liao River oil field, first developed in the late 1960s, has become China's fourth largest onshore producer.

Mineral resources and mining

Rich reserves of manganese ore occur in western Liaoning and in the southeast. In the eastern mountain area there are substantial deposits of copper, lead, and zinc; smaller similar deposits occur in the west, together with an important deposit of molybdenum. Important concentrations of magnesium ore are found southwest of Shen-yang. There are also reserves of other minerals, including bauxite, gold, and diamonds, and sea salt is produced.

Agriculture, forestry, and fishing. Agricultural advances in Liaoning have been less spectacular than industrial development. There are several reasons for this. Investment has always been much heavier in industry than in farming. The province's inheritance from the Japanese phase was much less valuable in agriculture than in industry. Liaoning also suffers from both natural calamities, such as spring droughts, and from backward cultivation methods in many places, which result in low yields. Exceptional opportunities for employment in industry also tend to deprive agriculture of much of the best labour, in spite of policies designed to prevent this. Yet, in much of Liaoning, topography and soils, and even climate, are quite favourable to agriculture; and the degree of farm mechanization, irrigation, and chemical fertilization is very high by Chinese standards. Liaoning is, nevertheless, an importer of food. It must depend partly on food from Kirin and Heilungkiang to the north and partly on imported grain.

Agricultural problems

The summer in Liaoning is not long. Few places, consequently, produce two crops per year. The central plain is the best farming area, and the Liaotung Peninsula, with its shorter winter, has a diversified agriculture. Peanuts (groundnuts), sugar beets, and pears are among the province's major crops. Part of the cultivated area is used for industrial crops (primarily cotton and tobacco) or for export crops like apples; the rest is used for grain crops, vegetables, and soybeans. Higher yielding corn and rice, formerly grown mainly in the east and the southeast, have tended to supplant millet and kaoliang (a variety of grain sorghum) in the plains. The chestnut-leaved oak feeds the tussah silkworm; Liaoning is China's major producer of tussah silk. The forests support commercial lumbering, but the supply of mature trees is limited, due to previous overexploitation, and the output of lumber is low.

Livestock raising is of minor importance. Pigs are bred mainly in the south and central parts, and in the west other animals are raised. Fishing in the Yellow Sea, on the other hand, is a major income-earning activity.

Industry. During the mid-1950s considerable capital investment was made in Liaoning, primarily in heavy industry. In heavy industrial production, Liaoning ranks first among the provinces of China, producing, in addition to pig iron and steel, a substantial part of China's cement, crude oil, and electrical power. Apart from iron and steel, the industries of Liaoning include nonferrous-metal processing, machinery manufacture, and chemical manufacture, as well as such light industries as those producing textiles, foodstuffs, and paper.

The primary focus of investment in Liaoning has been the industrial network centred on the An-shan iron and steel complex. An-shan, south of Shen-yang, is the industrial heart of Liaoning and is China's principal steel

Gillhausen—*stern* from Black Star

Strip-mining a coalfield in Fu-shun, Liaoning Province.

Principal industrial areas

centre; taken as a whole, it is the biggest single enterprise in industrial investment ever established in China. Shen-yang, also a key industrial city, has been granted provincial-level powers in economic planning. It has a wide and varied range of heavy and light industries. Fu-shun is part of the Shen-yang complex, but its industries are all based on coal. Liao-yang, directly south of Shen-yang, is a textile centre. Lü-ta, near the tip of the Liaotung Peninsula, is of obvious strategic importance. It has the best harbour in the Northeast and is a major Chinese port. Modern engineering industries have been developed there, including shipbuilding and locomotive production. Lü-ta also has provincial-level economic authority and is one of China's coastal cities open to foreign investment. Western Liaoning, centred on Chin-chou, is less advanced than the Shen-yang–An-shan area or Lü-ta, but it has valuable mineral resources and some industries.

Transportation. The rail transportation facilities of Liaoning are the best in China, and the tonnage transported is also the second highest for any province. The backbone of the transportation system is the Ch'ang-ch'un–Lü-ta railway (formerly called the South Manchurian Railway), which passes through Shen-yang and which was double-tracked in 1954. Rail traffic primarily comprises either industrial freight or food products in bulk.

Highways in the province are extensive, but many are of poor quality. Many of the goods transported by road are carried in carts by animals in the traditional style.

Shipping

Navigation by sea or river carries almost none of the internal traffic of Liaoning, but sea navigation is of great importance for transport to other parts of China. Lü-ta is the largest port, followed by Ying-k'ou.

Administration and social conditions. *Government.* From 1950 to 1954 Liaoning, divided into Liaotung and Liaosi, was under the jurisdiction of the Northeast Military Administrative Commission. In 1954 the province was reunited, and Liaoning was brought under direct central government rule. During the Cultural Revolution the province was in the forefront of radical reform; it continued to support many of the revolution's initiatives after the death of Mao Zedong (Mao Tse-tung) in 1976, although Liaoning subsequently led the national effort to modernize its industrial plants and open its doors to trade with the outside world. Liaoning Province (*sheng*) is now divided into two prefectures (*ti-ch'ü*) and 10 municipalities (*shih*) at the prefecture level. All of the province's counties (*hsien*) are under municipal administration.

Education. Liaoning's economically advanced society has developed significant educational and scientific resources. Only the three province-level cities of Shanghai, Tientsin, and Peking have a greater proportion of population educated at least to the primary level. Liaoning is second only to Peking in adult literacy and has more scientists and technical staff than Shanghai. There are numerous universities and other post-secondary educational institutions in the province.

Culture. Though Sinitic in tradition, Liaoning's culture has been shaped by a kind of "outsider" perspective. Long periods of non-Han rule and the late onset of significant migration to the area have given Liaoning a frontier character. Many of the clan-centred traditions of central and South China have been attenuated in this still mobile society, where roots are shallow and the nuclear family predominates. In addition, as an arena of competition for influence by the Japanese and the Russians, the province has a degree of cosmopolitanism lacking in many other areas of China.

HISTORY

Most of the present province of Liaoning fell within the confines of the earliest Great Wall of China, built during the reign of the first Ch'in emperor (221–210/209 BC), and hence formed part of China from early times. The environment and traditional Chinese civilization of the central plain in Liaoning continue into the North China Plain and into Shantung to the south. Political power in the region often passed to nonagricultural peoples, such as the Khitan, who invaded the area in the 10th century AD and established the Liao dynasty, and the Juchen, who founded the Ch'in dynasty in the 12th century. During the Yüan dynasty, Chinese (Mongol) power was reasserted over the region, and ties remained relatively close through the Ming dynasty. Chinese immigration from the south also has a long history, but until the last years of the 19th century it was on a modest scale. The traditional economy of Liaoning was one of Chinese peasant farm production in the plains; on the peripheries the economy was based in various places on herding, forestry, fishing, mining, and estate farming. Neither the aristocratic holders of the landed estates nor the people who depended on animals or on the products of the forests or rivers were generally Chinese; as elsewhere in the Northeast, they were of Mongol or Manchu stock.

Under the Ch'ing dynasty (1644–1911/12), whose own origins lay in the Manchu frontier aristocracy, official efforts were made to protect the Northeast from Chinese encroachment with the exception of the old Chinese-settled area in the Liao Valley. This policy was gradually abandoned, partly because of the pressure of Russian influence in the north.

Toward the end of the 19th century and into the 20th, two intersecting forces together created a radically novel situation in Liaoning. One was foreign interference—Russian and, later, Japanese. The other was rapidly increasing Chinese immigration. These two forces resulted in the expansion of the economy of Liaoning at a wholly unprecedented rate. Immigrants traveled to Liaoning both by the Shan-hai-kuan land corridor in the southwest and from Shantung by sea to the Liaotung Peninsula in the east. The second group were the more numerous and have been the more successful, both because of the relative ease of travel by sea and because of the better opportunities for both work and settlement in Liaotung. During the first half of the 20th century, the population of the province rose to a size proportionate to its present figure. The population movement was based on seasonal migration for farm work, with about half of the migrants remaining in Manchuria after the harvests each year. Many strong Shantung communities grew up in Liaotung, with traditions of mutual dependence and help.

Patterns of Chinese immigration

The all-important South Manchurian Railway was constructed by the Russians between 1896 and 1903. This railway linked the new Liaotung port of Lü-ta with Ch'ang-ch'un, in Kirin Province, as well as with Harbin in Heilungkiang Province, and with the then new Chinese Eastern Railway branch of the Trans-Siberian Railway. The South Manchurian Railway passed close to Shen-yang, replaced navigation on the Liao and much of the old cart transport, and bypassed the old port of Ying-k'ou. The foundations of the modern geography of Liaoning were laid by this railway. In 1907 the Russian railway, port, and territorial privileges were transferred to Japan at the conclusion of the Russo-Japanese War of 1904–05. From that time, Japan continually strengthened its hold on the economic life of Liaoning and all of Manchuria, partly through physical control but also through an active and successful policy of investment and economic expansion. From 1932 to 1945 Liaoning was part of the Japanese-dominated, "independent" state of Manchukuo. Throughout this period, which included the Sino-Japanese War and World War II (1937–45), Japanese policy aimed to develop the resources of Liaoning in a manner that would complement the economic strength of Japan. Heavy industry was particularly developed. This concentration on heavy industry at the expense of light industry and agriculture has been criticized; but, in the face of China's general lack of heavy industrial capacity, these installations have stood her in good stead since 1949.

The period of Japanese domination

Shen-yang fell to the Chinese Communists in 1948. The industrial installations of Liaoning had suffered heavily from war damage and from Soviet seizures of stockpiles and machinery. The new government made the restoration of the Northeast one of its first priorities. After the defeat of the Japanese in 1945, the Soviet Union took over from Japan and retained residual rights to share with China the use of the naval base facilities at Lü-shun and some rights on the former South Manchurian Railway. These rights were given up in 1955. (F.A.L./V.C.F./Ed.)

NORTH CHINA

Honan

Honan (Ho-nan in Wade–Giles romanization, Henan in Pinyin), a small province in the north central part of China, has an area of 64,700 square miles (167,700 square kilometres). The province stretches some 300 miles (500 kilometres) from north to south and 350 miles east to west at its widest point. It is bounded on the north by Shansi and Hopeh; on the east by Shantung and Anhwei; on the west by Shensi; and on the south by Hupeh. The Huang Ho (Yellow River) divides the province into two unequal parts—one-sixth north and five-sixths south of the river—and thus to some extent belies the name Honan ("South of the River"). K'ai-feng, the former capital, has been superseded by Cheng-chou, where the Peking–Han-k'ou railway crosses the Huang Ho and meets the Lung-hai Railway running from east to west.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Honan can be divided topographically into two parts, the western highlands and the eastern plain. In the northwest the rugged T'ai-hang and Chung-t'iao mountains form the steep eastern edge of the Shansi Plateau, rising in places above 5,000 feet (1,524 metres). They are part of the T'ai-hang fold system of Permian times and have a general northeast to southwest trend. They mark the northern border of the province.

The western highlands

South of the Huang Ho there is a broad stretch of upland comprising a number of moderately high mountain basins, the main ranges being the Hsiung-erh and Fu-niu. These mountains, which have an east–west trend, are the eastern extension of the Tsinling Mountains axis that divides China geologically and geographically into North and South. The T'ung-pai and Ta-pieh ranges form a further extension of this axis, running in a southeasterly direction and marking the border between Honan and Hupeh. The T'ung-pai range is separated from the Fu-niu by a gap some 75 to 100 miles wide cut by the T'ang and T'ao rivers, which are tributaries of the Han River. This gap gives easy access from the Honan Plain to the central basin of the Yangtze, a route much used from Han times onward in Chinese expansion southward.

To the east lie the plains. Until fairly recent geological times the mountains in the west (the western extension of the present Po Hai [Gulf of Chihli] and Yellow Sea) formed the coast of a sea. That sea, now filled with silt brought down by the rivers and by the wind from the Loess Plateau, forms the North China Plain and the Huai Basin. It is part of the great Neo-Cathaysian Geosyncline (downward-sloping part of the Earth's crust), which extends from Heilungkiang to Kiangsi provinces. The floor of this geosyncline is sinking at a rate equal to that of deposition; it is estimated that the sediment of the plain is now 2,800 feet deep in places.

Drainage. Honan has three river systems: the Huang Ho in the north and northeast, the Huai River in the east and southeast, and the T'ang and T'ao rivers in the southwest. The Huang Ho—known in Chinese literature simply as the Ho ("River")—immediately after its confluence with the Wei River, at the Shansi provincial border, turns eastward at T'ung-kuan to flow directly across the north of Honan. Near T'ung-kuan it enters the San-men Gorge of some 80 miles, thence issuing onto the plain. It is remarkable that from T'ung-kuan to the sea, a distance of some 600 miles, the Huang Ho receives only two comparatively small tributaries: the right-bank Lo River, on which Lo-yang stands, and the left-bank Ch'in River.

The Huang Ho

The Ho is subject to very great changes in summer and winter flow. In time of maximum flow (summer) the river carries an enormous load of silt, gathered mainly in its course through the Loess Plateau of Shensi and Shansi provinces. There is a Chinese saying that "if you fall into the Huang Ho you never get clean again." While the river is fast flowing in the San-men Gorge, it is able to carry its load of silt, but when it issues onto the plain its pace is checked. It can no longer carry the silt, and flooding occurs. Throughout historical times this menace has been met by building levees to contain the waters. Generally these dikes were built five to eight miles apart, parallel to the river's banks, to give the river plenty of room in time of spate (flooding), but instead the load of silt has been slowly spread, building up the riverbed through the centuries, until today it lies above the surrounding countryside. Dikes have been built higher and higher, and when they failed to hold—as has happened in some part of the province almost every year—the river descended onto the plain, causing disastrous floods, the waters of which could not return to the high streambed when the river's flow slackened. The result was waterlogging of the soil, crop destruction, and famine. Because the watershed between the Huang and Huai rivers is almost imperceptible, the Huang Ho has radically changed its course several times in the last three millennia, flowing to the sea, first south, then north, of the Shantung Peninsula. The diversion has always been in northern Honan between Cheng-chou and K'ai-feng. In 1938 in an attempt to arrest the advance of the invading Japanese Army, the Huang Ho was deliberately diverted by blowing up the dikes near Cheng-chou and flooding 21,000 square miles of land, at an estimated cost of 900,000 lives. The river was restored to its former northern course in 1947. Under the People's Republic, work along the river has included continued strengthening of the dikes and construction of the 30-mile-long People's Victory Canal, which diverts Huang Ho water to the Wei River. A dam near the city of San-men-hsia near the Shansi border was begun in 1956 as part of an extensive flood-control and hydroelectric project. After completion of the dam in the 1970s, silt accumulation cut its generating capacity to one-quarter of planned output, hampering much of the province's industrial development, but the dam proved valuable in taming the flood stages of the river.

The Huai itself and all its major left-bank tributaries have their sources in the mountains of western Honan. They flow eastward onto the Anhwei Plain, subjecting it to disastrous floods. In 1949 the Huai Basin became the Communist regime's first large water-conservancy program. Six dams were quickly built in the upper reaches of Huai tributaries in Honan. Since 1957 three very large dams at Lung-shan, Mei-shan, and Fo-tzu-ling have been built. Dikes were strengthened, with the result that no serious disaster has since occurred.

Huai Basin water-conservancy program

Soils. Honan's soils are made up mainly of calcium carbonate (lime) in hardened layers of alluvium. Because of the comparatively low rainfall, there is little leaching. The higher land of the west is mainly mountain yellow-brown earth, better drained than the plains. The more fertile areas fringing the plain were the sites of early civilization. Alluvium is spread throughout the plain; it is yellowish and gray, porous, granular, and poor in organic matter. Since the bed of the Huang Ho lies above the surrounding land, much of the low-lying land on either side is waterlogged. Consequently, soil salinity and alkalinity affect the whole area. There are large areas of bleak, white saline sands. Since 1949 there has been much experimentation aimed at bringing these alkaline lands into production. Between 1954 and 1964 one-fourth of the saline land between K'ai-feng and Cheng-chou reportedly was transformed into fertile farmland, and reclamation of saline and alkaline land has continued.

Salinity of the Huang Ho flood basin

Climate. Climatically, Honan lies in a transitional zone between the North China Plain and the Yangtze Valley. Although protected in some degree from the Mongolian winds by the T'ai-hang Mountains, Honan has very cold winters; summers are hot and humid. Average January temperature in the north is 28° F (−2° C) and in the south 36° F (2° C). Average July temperature over the lowlands is 82° F (28° C), while in the western mountains

it is a degree or two lower. There are 210 frostless days annually in the north and 250 in the south.

Rainfall is distributed more evenly throughout the year than it is in the rest of North China, although there is a marked spring–summer maximum. K'ai-feng has an average rainfall of 23 inches (580 millimetres), of which only three inches fall in the autumn and winter months. There is a steady decrease in total rainfall from southeast to northwest and a marked increase in variability. Honan is therefore more subject to years of alternating heavy rain and drought than the provinces of the Yangtze Valley. In the past it has suffered from severe famine. It also experiences spring cloudbursts and occasional hailstorms, both of which can be very destructive. In times of drought, summer dust storms are worse even than those of winter.

Plant life. The natural vegetation of Honan is deciduous forest and woodland over the plains, and deciduous and coniferous forest in the western highlands. Intensive settlement of the plains has long since led to the clearance of the trees to make way for cultivation. The mountains, however, retain some of their woodland. Since 1949 major efforts have been made in planting trees for shelter, timber, and other uses.

The people. Honan is China's second most populous province, with the overwhelming majority of the population living in rural areas. The greatest concentration of rural population is in the eastern plain. Nearly as great densities are found in the I and Lo river basins and in the plain around Nan-yang, but in the more mountainous west and south they are considerably less. On the eastern plain, villages are fairly close together, usually about one mile apart. In the mountains they are smaller and more widely dispersed. Houses are made mainly of mud-plastered walls and thatched roofs. There was considerable movement of rural people of the plains to towns in the west in 1958–59, during agricultural collectivization and the Great Leap Forward.

Ethnic homogeneity of Honan

The vast majority of the people of Honan is Han (Chinese). There are no autonomous minority groups such as are found in the western provinces, the small number of Hui (Chinese Muslims) being integrated into the broader population. Mongol and Manchu invaders were absorbed and Sinicized. In the 12th century, when K'ai-feng was the Imperial capital of the Sung dynasty, Jews, originally from India or Persia, became an important part of the community. They retained their identity until the 19th century but have since been absorbed.

Xinhua News Agency

Farm workers spreading harvested wheat to dry on the plain of the Huang Ho (Yellow River) in northern Honan Province.

The economy. *Agriculture.* Honan's economy is essentially agricultural. Most of the total cultivated area lies in the plains to the east of the Peking–Han-k'ou railway. The only idle land is found in the mountains and in the saline lands of the northeast. Main food crops include winter wheat, millet, kaoliang (a variety of grain sorghum), soybeans, barley, corn (maize), sweet potatoes, rice, and green lentils. Wheat is by far the most important, in both acreage and production, Honan ranking first in China's output. Rice occupies only a small percentage of the crop area; its yield per acre, however, is almost three times as great as that of wheat. Fruit growing has received considerable impetus in recent years, partly for its own sake and partly for soil conservation, particularly in the idle sandy lands of the northeast and on mountain slopes. Dates, persimmons, apples, and pears are the main fruits, with walnuts and chestnuts also grown. Honan produces draft animals of good quality, particularly yellow oxen and donkeys. Hogs are the most important food animals, and goats and sheep are raised in the western mountains.

The chief industrial crops are cotton, tobacco, vegetable oils, and silk. Cotton is widely grown on about half the acreage, with its main concentration north of the Huang Ho around An-yang and Hsin-hsiang. Tobacco growing, introduced in Honan in 1916, increased enormously after 1949; within 40 years Honan became China's largest tobacco producer. Vegetable oils are important, with Honan one of China's largest producers of sesame, grown mainly in the east and south. Ramie, the most important of the leafy fibres, is grown in east Honan in the Huai Valley.

Sericulture

Honan is one of the oldest centres of sericulture (silkworm raising) in China. The industry dates back to the Tung (Eastern) Han dynasty (AD 25–220). Both mulberry-leaf culture and oak-tree culture for silkworms flourished between the two world wars until suffering severely during the Sino-Japanese War. After 1949 there was a revival on the slopes of the Fu-niu Mountains, and the province became an important exporter of silk.

Honan suffers very severely at times from locusts, which winter in the arid, sandy alkaline soils beside the Huang Ho. Extended and improved cultivation in these areas has helped control the pest.

Industry. Although before 1949 there was little industrial development in Honan, subsequent industrialization was both rapid and extensive. Much of the development tapped Honan's rich coal seams in the northwest. Both bituminous and anthracite coal are found along the slopes of the T'ai-hang Mountains, and big reserves of good coking coal in thick, easily mined seams are found in the Fu-niu Mountains between Hsü-ch'ang and P'ing-ting-shan. Iron ore is found at Ju-yang on the Ju River in the Hsiung-erh Mountains, as well as some pyrite, bauxite, and mica. Large coal mines at Chiao-tso supply the fast-growing industries of Lo-yang, Cheng-chou, K'ai-feng, and Hsin-hsiang but are still inadequate. The vast coalfield at P'ing-ting-shan has been worked since 1964.

Honan is a significant producer of energy, with thermal plants in Cheng-chou, Lo-yang, K'ai-feng, and Hsin-hsiang linked by a power line. An ultrahigh-voltage transmission system, one of the largest in China, began transporting electricity from the P'ing-ting-shan coal-mining area to Wu-ch'ang in the early 1980s. There are large proven reserves of low-sulfur petroleum and natural gas at the Chung-yüan complex of oil fields.

China's first tractor factory

Lo-yang was chosen as the site for China's first tractor factory, opened in 1958. Since then its output has burgeoned, and Lo-yang has become a heavy-industry centre. Cheng-chou lies in the heart of the cotton-growing area and is now the centre of the textile industry. K'ai-feng, Imperial capital of the Sung emperors, declined after the 11th century—especially when the Huang Ho dikes were broken and the region was ruined in 1642. A large chemical-fertilizer works and a tractor-accessories plant have led to its revival. Hsin-hsiang, the most important city of north Honan, is the centre of the railway network of the area. Emphasis has shifted over the years from development of heavy to development of light industry. Thus,

there has been a growth in the production of consumer goods such as cigarettes, electronic products, bicycles, household appliances, textiles, and tableware. Tourism is a major earner of foreign exchange.

Transportation. Although the Huang Ho flows through north Honan, it serves it poorly as a line of communication. Within the province it was navigable only in the Sanmen Gorge until the construction of the dam there. Even now it is useful over the plain only for small rivercraft. The Huai and its tributaries flowing down from the western mountains are rapid in their upper courses and silted in their lower, so that they, too, serve only small craft. The Wei, flowing north into the Hai system, has been joined by the People's Victory Canal to the Huang Ho. In 1964–65 it was successfully dredged in an experiment aimed at deepening the riverbed and so increasing flow and reducing waterlogging. Cheng-chou is the junction of China's two greatest trunk railways, the Peking–Han-k'ou–Canton line and the Lung-hai line, which runs from the east coast to Sinkiang, in the far west. Local railroads have also been developed, and most of the province's goods are now carried by rail. The first modern roads in Honan date from the famine of 1920–21, when the American Red Cross built earth tracks to bring relief to the stricken provinces. Since 1959 the great bulk of road building has been done with little modern technology; some roads penetrate the more remote mountain region, as, for example, a road in the T'ai-hang Mountains between Hui-hsien and Ling-ch'uan. Most of the highways have all-weather surfaces.

Administration and social conditions. *Government.* On the victory of the Communists in 1949, Honan, together with Hupeh, Hunan, Kiangsi, Kwangtung, and Kwangsi, formed the Central South greater administrative region. In 1954 provincial government was established, and for local governmental purposes Honan has been subsequently divided into eight prefectures (*ti-ch'ü*) and nine prefecture-level municipalities (*shih*). Below this level the province is divided into counties (*hsien*) and county-level municipalities (*shih*). The province was badly affected by political conflict during the Cultural Revolution. During much of that time it was governed by a provincial Revolutionary Committee, which consisted of 11 members, nine of whom were selected from the People's Liberation Army, one from the "revolutionary cadres," and one from the "revolutionary masses." The Revolutionary Committee was replaced in 1980 by the People's Government, which is the administrative arm of the People's Congress. The People's Congress, acting largely through its Standing Committee, is an organ of the state, and its powers include enacting legislation, implementing state policies, and approving provincial economic plans and budgets. Its members are elected by the People's Congress at the next lower administrative level, and it in turn elects the members of the People's Government.

Education. Since its Imperial days K'ai-feng has remained the cultural and educational centre of Honan, although it has come to share that role with Cheng-chou. The first impact of Western learning came, as in the rest of China, through the primary and middle schools of Christian missions. Little real progress was made in the turbulent years between 1911 and 1949, and the vast mass of the people remained illiterate. Successful efforts were made by the government in the first years after 1949 to overcome illiteracy, and a real attempt at universal primary education was launched. Education is now based on six years of primary schooling and six years of secondary schooling. Honan has more than 30 institutes of higher learning.

Health and welfare. Modern Western medicine, like education, was introduced by Christian missions but made very little impact on the vast area of Honan. On attaining power in 1949, the People's government concentrated attention on public hygiene and preventive medicine. A doctor's training was cut from six to three years, and teams were dispersed throughout the province to teach hygiene, vaccinate, inoculate, and advise. Although a doctor's training has now reverted to six years, emphasis remains on the "barefoot doctor," midwife, and health worker. With the great development of coal mining in Honan, attention has been focused on silicosis prevention, which is being achieved mainly by improving working conditions. Kala-azar, the debilitating disease carried by sand flies, is also receiving special attention. As elsewhere in the country, traditional Chinese medicine has gained status.

Emphasis on the "barefoot doctor"

Cultural life. In an essentially agricultural province such as Honan, cultural life is centred in the rural community. While families, for the most part, retain and own their own homes, cultural life is focused in the community centre, with its reading room, library, and teahouses, in which the old tradition of storytelling has continued and is very popular. Loudspeaker radio is used to ensure communication. Traditional local music forms—such as the *chui-tzu* ballad and *yu-chü* opera—are popular, as are the performances of the province's many art troupes.

HISTORY

Honan abounds in prehistorical and early historical interest. Some of the most important evidences of the Neolithic beginnings of Chinese civilization are found in the northern part of the province. It was at Yang-shao in north Honan that a Swedish geologist and archaeologist, Johan Gunnar Andersson, in 1921 discovered an assemblage of Neolithic painted pottery that, together with many later finds, marked the presence of a well-established primitive farming culture, which has been named Yang-shao. The early farmers occupied the lands at the confluence of the Huang, Wei, and Fen rivers, the cradle of Chinese civilization. The other main Honan sites of the culture are at Miao-ti-kou, Lin-shan-chai, P'an Nan, and Hsi Yin. The early farmers, who were also part-time hunters and fishermen, lived in sunken circular or rectangular dwellings, sometimes of considerable dimensions. They grew foxtail millet, broomcorn millet, and kaoliang and had domesticated dogs and pigs. Cultivation with their primitive stone tools was comparatively easy in the easily worked loess (wind-borne) soil.

Cradle of Chinese civilization

Immediately to the east, at Lung-shan in Shantung Province, a different culture was discovered, known as the Black Pottery culture, as distinct from the slightly earlier Painted Pottery culture (Yang-shao culture). It was on these Yang-shao–Lung-shan foundations that the early civilization of the Shang (Yin) dynasty arose (18th–12th century BC) in north and west Honan, south Hopeh, and west Shantung. Excavations near An-yang and in Cheng-chou and Hsing-t'ai, Hopeh, revealed an advanced culture, having a hierarchical class structure, advanced buildings, and elaborate ritual in which beautiful bronze vessels were used. Based on the dating of oracle bone inscriptions, the Shang king P'an K'eng moved his capital to a site near An-yang in 1384 BC.

When the Shang kingdom fell to the Chou dynasty (1111–255 BC), An-yang lost its status as a capital. When the Chou capital, Hao (near modern Sian in Shensi Province), was destroyed in 771 BC by western tribes, Lo-yang (then known as Lo-i) took its place. During the period 771 BC to AD 938, the distinction of being the capital was shared alternately by Lo-yang and Ch'ang-an (modern Sian). Lo-yang was the capital during the following dynasties—the Tung (Eastern) Chou (771–256/255 BC), Tung Han (AD 25–220), Wei (220–265/266), Hsi (Western) Chin (265–311), Wei (386–534/535), and Hou (Later) T'ang (923–936/937). With the fall of the T'ang dynasty in 936/937, K'ai-feng, then called Pien, became the nation's capital and remained so until the Pei (Northern) Sung dynasty was overthrown by the Juchen invaders in 1126. After the sack of K'ai-feng in 1127, the Honan region continued to be the chief source of grain for Imperial storehouses. Both Lo-yang and K'ai-feng remained important because of their strategic locations in the gateway leading from the North China Plain into the Huai Basin, thence into the Yangtze Basin. Cheng-chou became important in the early 20th century as a railway junction and was made the provincial capital in 1954. (T.R.T./V.C.F.)

Hopeh

Hopeh (Ho-pei in Wade–Giles romanization, Hebei in Pinyin) is a province in northern China on the Po Hai

(Gulf of Chihli) of the Yellow Sea. It is bounded on the northwest by China's Inner Mongolia Autonomous Region and by the provinces of Liaoning on the northeast, Shantung on the southeast, Honan on the south, and Shansi on the west. Hopeh means "North of the (Yellow) River." Hopeh has an area of 72,500 square miles (187,700 square kilometres). The provincial capital was at Paoting until 1958, when it was transferred first to Tientsin and then, in 1967, to Shih-chia-chuang, 160 miles (260 kilometres) southwest of Peking. The present capital is at the junction of three railways: the Peking–Canton line, China's north–south trunk line, and lines to Shansi and to Shantung. The large municipalities of Peking, the national capital, and of Tientsin lie within Hopeh Province but are independent of the provincial administration. Culturally and economically, Hopeh is the most advanced province in northern China.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Hopeh Province consists of two almost equal sections: the northern part of the North China Plain and the mountain ranges along the northern and western frontiers. The former is sometimes called the Hopeh Plain. It is formed largely by the alluvial deposits of the five principal tributaries of the Hai River, which flows past Tientsin to the sea. Two of them, the Yungting and the Pai, flow down from the northern highlands. The other three have their sources in the western part of Hopeh: the Ta-ch'ing and Tzu-ya rivers and the Southern Grand Canal (Nan-yün Ho).

Hopeh Plain

The Hopeh Plain slopes gently from west to east. It is bounded by the Yen Mountains on the north, the T'ai-hang Mountains to the west, and the Po Hai to the east. The mountains have at their base a string of alluvial fans. This inner belt of the Hopeh Plain is generally well drained. The groundwater level is usually less than 33 feet (10 metres) from the surface and is easily tapped for domestic water and irrigation.

The Yen Mountains form the northern rim of the North China Plain, displaying to the traveler an endless sea of rounded hills, with peaks averaging 4,900 feet above sea level. The Great Wall of China zigzags along its crests.

Ellen Warner—Black Star

The Great Wall of China as it traverses the crests of the Yen Mountains in Hopeh Province.

Beyond these mountains the Mongolian Plateau stretches from the northernmost part of Hopeh Province to the Mongolian People's Republic. This part of Hopeh was incorporated into the province in 1952, when Hopeh's boundaries were extended beyond the North China Plain for the first time. The rim of the plateau has an average elevation of 3,900 to 4,900 feet and is rugged and inhospitable to human settlement. Between the Yen Mountains are large basin plains, cultivated and well inhabited. Coal and iron are mined in the northern mountains.

To the west of the North China Plain sprawls the lofty north–south range of the T'ai-hang Mountains, separating the Hopeh Plain from the Shansi Plateau, its highest peak rising more than 9,000 feet. The range is pierced by a number of west–east streams whose narrow valleys (the famous "Eight Gorges" of T'ai-hang) are the routes of highways and railroads between the Hopeh Plain and the Shansi Plateau.

Drainage and soils. The major Hopeh rivers flow down from the loess-covered T'ai-hang Mountains and the Shansi Plateau. They carry a heavy load of silt after the summer downpours, depositing it in the shallow channels downstream on the plain, gradually silting them up and causing widespread floods in low-lying areas. Since 1949 vigorous measures for water control and soil conservation have been carried out together with reforestation in the upland areas. Numerous dams, generally small to medium-size, have been built upstream and in the tributaries to conserve the water for irrigation and other uses; flood-retention basins and storage reservoirs have been built downstream. The Tu-liu-chien River, connecting the Ta-ch'ing to the sea, helps to drain the extremely low-lying tract around the large Pai-yang Lake and the Wen-an Marsh. Water from the streams is used to wash away excess salt in the alkaline soil and to make it arable. Similar *chien-ho* ("reducing streams") have been completed for the Southern Grand Canal.

Rivers

The Hai River is only 35 miles long, from the city of Tientsin to the sea, but the drainage basin of its five tributaries covers two-thirds of the province. A number of flood-control and power-generation projects have been developed in the Hai Basin, including reservoirs to the northeast and northwest of Peking. Another major river is the Luan, which drains northeastern Hopeh. A major project of the 1980s was the construction of a diversion channel carrying water from the Luan to Tientsin. All the major Hopeh rivers empty into the Po Hai, a shallow sea with an average depth of only 100 feet. The water and nutrient matter brought down by the rivers nourish a rich marine fauna. In winter the surface water along the coast is frozen, but navigation is possible with the use of ice-breakers. There are three important ports: Tientsin, which is about 35 miles up the Hai, T'ang-ku, and the major coal-handling and oil-shipping port of Ch'in-huang-tao.

The most common soil in the Hopeh Plain is dark-brown earth developed on loessial alluvium, modified by cultivation over several millennia. It is extremely fertile—the famous "good earth"—yielding crops with little fertilization for thousands of years. New alluvium is distributed in the areas along the rivers by frequent flooding. In the mountains the soils vary: the upland hills have leached dark-brown soils, the more humid mountainous areas of the Yen and T'ai-hang ranges have brown forest soils suited to fruit trees, and the northernmost Chang-pei plateau has light-chestnut zonal soils.

Climate. The province has a continental climate. The January mean temperatures range from 25° F (−4° C) in the south to 14° F (−10° C) north of the Great Wall. The average July temperature is about 77° F (25° C) in the North China Plain, and 73° to 77° F (23° to 25° C) in the northern and western highlands. The annual precipitation (rain and snow) is more than 20 inches (500 millimetres) in most parts of the province. The summer months of June, July, and August are the rainy season.

Plant and animal life. The natural vegetation of the greater part of the province is broad-leaved deciduous forest, but, after many centuries of human settlement, cultivation, and deforestation, little of the original vegetation remains except in the high mountains and other inac-

cessible areas. Annual afforestation projects have seeded millions of acres in an effort to develop the forest upland economy.

The northernmost Chang-pei plateau has steppe grass of the Mongolian Plateau type. The higher mountains have coniferous forests. In the saline areas along the coast and in the low-lying depressions, plants that flourish in a salty environment dominate. There is a conspicuous absence of forests in the lowlands and lower hills. The flora is predominantly of a northern character. It includes the willow, elm, poplar, Chinese scholar tree (*Sophora japonica*), tree of heaven (*Ailanthus*), and drought-resistant shrubs.

Animal life

The present fauna includes elements of the temperate forest (such as the forest cat *Felis euptilus*) and of the cold-winter steppe (such as the camel), as well as some tropical elements from the Indo-Malay region (such as the tiger and monkey). The domestication of animals such as the dog, sheep, goat, cow, horse, donkey, mule, camel, and cat has led to the extinction or near-extinction of many wild species. The smaller mammals are better preserved, including moles, bats, rabbits and hares, rats, mice, and squirrels. Birds include the Mandarin duck (*Aix galericulata*), native to China. The Hopeh Plain was the home of Peking man, an extinct hominid of the species *Homo erectus*, who lived about 460,000 years ago and used tools and fire.

The people. The ethnic composition of the population is almost entirely Han (Chinese). Minority groups include the Hui (Chinese Muslims) and a tiny percentage of Mongols. Since nearly one-half of Hopeh Province is mountainous, the density of population is really much higher than the average of about 750 persons per square mile (300 per square kilometre) suggests. The highest population densities in Hopeh are found at the foot of the T'ai-hang Mountains, in the belt of alluvial fans. This is a district settled since antiquity, on the ancient highway from the Chung-yüan, or "Middle Plain," of the North China Plain to Peking and on to the regions north of the Great Wall. These piedmont plains have also been settled since ancient times. The rural settlement pattern is that of huge nucleated villages. Farther east and south of the alluvial-fan belt are the low-lying districts subject to flood, which have somewhat lower densities. The area north of the Great Wall and the remote mountainous areas have the lowest densities. Before 1949 there was substantial migration from northwestern Hopeh to Inner Mongolia. Peasants in southeastern Hopeh have also migrated in large numbers since the beginning of the 20th century to Inner Mongolia and China's northwest and the Northeast.

The economy. *Agriculture.* Hopeh is important for its production of cotton, wheat, corn (maize), peanuts (groundnuts), and fruit. The widespread introduction of tube-well irrigation in the late 1960s and early '70s made Hopeh and Kiangsu among the leading provinces in irrigated acreage.

Industry. Hopeh lies at the heart of one of two major industrial regions in China. The province developed a modest industrial base from the late 19th century onward, chiefly in coal, iron, textiles, and indigenous handicrafts. Tremendous industrial expansion took place during the 1950s: the spinning capacity of Hopeh's cotton belt was expanded considerably; a major coal belt, which stretches in a crescent through Hopeh and into northern Honan, provided the impetus for significant expansion of the coal-mining industry; and the incorporation into Hopeh (1952) of the Lung-yen iron-ore district of former Chahar Province speeded the development of the iron and steel industry. In the 1960s the emergence of the Hua-pei oil fields made Hopeh a major oil producer, and in 1983 China's first deep-horizon oil field, the Ma-hsi field, went into operation in the southern section of the Ta-kang oil field on the Po Hai coast, producing significant quantities of oil and natural gas.

Peking–Tientsin industrial region

These industries became the basis of the Peking–Tientsin industrial region, the largest and most important industrial centre in North China. Industrial production has diversified and expanded to include such key products as cement, agricultural equipment, and fertilizer. Light industries include textile and ceramics manufacture, food processing, and paper and flour milling. Tientsin, the region's second largest city, is the primary industrial and commercial centre of North China and the second most important trade centre in all China. Other major industrial cities of the region include T'ang-shan (largely rebuilt since an earthquake in 1976) and Ch'in-huang-tao, in eastern Hopeh; Pao-ting; Shih-chia-chuang, in western Hopeh; and Liu-li-ho, in Peking Municipality.

Transportation. Hopeh is well served by railroads. The province is at the centre of China's vast north–south railway network, and all of its major cities are connected by rail. Sea transport moves through Tientsin and Ch'in-huang-tao. The port of Ch'in-huang-tao was first opened to commercial activity in 1898; it is now one of China's "open" coastal cities, which play a key role in the country's foreign trade and investment. The port ranks third nationally after Lü-ta (formerly Dairen) and Shanghai in handling capacity.

Administration and social conditions. *Government.* Hopeh Province (*sheng*) is divided into nine prefectures (*ti-ch'ü*) and nine prefecture-level municipalities (*shih*). Below this level the province is divided into counties (*hsien*) and county-level municipalities (*shih*). The traditional subcounty administrative unit was the civil township, or rural district (*hsiang*), which was supplanted in 1958 by the commune. The communes were in turn replaced by the *hsiang* after the Cultural Revolution.

Administrative levels

Education. Public education has made major strides since 1949. The great majority of adults are now literate, and well over half of the population has received at least a primary school education. With more than 30 institutions of higher education, the province has sought to upgrade the technical level of its citizens as part of a drive toward modernization. The emphasis on broadening opportunities for education has led to the establishment of television and radio universities for part-time and continuing study, while vocational secondary schools serve the needs of Hopeh's industry.

Cultural life. Hopeh is linguistically and culturally part of the Northern Mandarin dialect area and shares many of the features of that regional culture. Living in the northernmost part of the Sinitic zone—historically subject to nomad incursions and political subjugation—Hopeh's people are traditionally depicted as orderly, submissive, and uncomplaining. Their cuisine features wheat cakes, mutton, and bean dishes. There are many local operatic and dramatic traditions, carried on by the province's numerous art and theatre troupes.

HISTORY

Although the area of present Hopeh Province was settled very early, it lay for many centuries outside the sphere of most political and economic activity of the Chinese empire. Before incorporation into the Ch'in Empire in the 3rd century BC, the region was occupied by the states of Yen, Ch'i, and Chao.

Hopeh has long been an area of strategic significance. To the rulers of the Han dynasty (206 BC–AD 220), it was largely a frontier zone beyond which lay their main enemies, the Hsiung-nu people, and defense of the region with walls and permanent garrisons was therefore emphasized. To the expansionist emperors of the T'ang dynasty, Hopeh served as a starting point for large campaigns aimed at the conquest of Korea. In AD 755, military forces stationed in the area were used to temporarily overthrow T'ang rule in a revolt led by An Lu-shan. Hopeh grew in importance under the rule of a series of northern-based dynasties, including the Liao, or Khitan (907–1125); the Chin, or Juchen (1115–1234); and the Yüan, or Mongol (1206–1368). Peking first became the capital of all China under the Yüan rulers, who also completed work begun by the Chin on the Grand Canal linking Hopeh to the rice-growing regions of southern China.

Hopeh under T'ang rule

During the Ch'ing, or Manchu, dynasty (1644–1911/12) Hopeh was called Chihli ("Directly Ruled") Province and continued to be strategically important, especially as foreign imperialist pressure mounted during the 19th century. Li Huang-chang, the foremost military and political leader of his time, served for many years as governor general of

Chihli and was succeeded by Yüan Shih-k'ai, who became president of the Chinese republic in 1912. A period of domination by a succession of autonomous warlords in Hopeh followed Yüan's death in 1916. The warlord Yen Hsi-shan continued to govern independently in Hopeh until the Japanese invasion of 1937. After Japan's defeat the occupiers surrendered to the Chinese Nationalists in 1945. Chinese Communist forces took the province in January 1949, opening a new chapter in its long history.

Peking

For coverage of Peking, see the *Macropædia* article PEKING.

Shansi

Shansi (Shan-hsi in Wade–Giles romanization, Shanxi in Pinyin), a province of northern China, has an area of about 60,200 square miles (156,000 square kilometres). Roughly rectangular in shape, Shansi is bounded by the provinces of Hopeh to the east, Honan to the south and southeast, and Shensi to the west and by the Inner Mongolia Autonomous Region to the north. The name Shansi ("Western Mountains"), testifies to the rugged terrain of the territory. The largest city and provincial capital, T'ai-yüan, is located in the centre of the province.

Shansi has always held a strategic position as a gateway to the fertile plains of Hopeh and Honan. Since ancient times it has also served as a buffer between China and the Mongolian and Central Asian steppes. A key route for military and trading expeditions, it was one of the major avenues for the entrance of Buddhism into China from India. Today it is important for its vast reserves of coal and iron, which form the basis of heavy industrial development, and for its production of cotton for export.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Two-thirds of the province is composed of a plateau, part of China's vast Loess Plateau, that lies at elevations between 1,000 and 3,000 feet (300 and 900 metres) above sea level. The plateau is bounded by the Wu-t'ai and Heng Mountains on the north, the T'ai-hang Mountains on the east, and the Lü-liang Mountains on the west. The eastern mountains average between 5,000 and 6,000 feet in height and reach their maximum elevation at Mount Shih-ku (8,300 feet), located in Hopeh Province. The highest peak in the west, Mount Kuan-ti, reaches an elevation of 9,288 feet, while the northern ranges are crowned by Mount Wu-t'ai at 10,033 feet.

Mountains and plateaus

Wang Wenxue—Xinhua News Agency

The white pagoda of T'a-yüan Temple in the Wu-t'ai Mountains, Shansi Province.

The Huang Ho (Yellow River) flows through a mountain gorge from north to south and forms the western border with Shensi Province. At Feng-ling-tu the river turns sharply eastward and forms part of the southern border with Honan Province. The southwest corner of the province is part of the highland region that extends from Kansu to Honan provinces and is covered with a layer of loess. The Fen River Valley comprises a chain of linked, loess-filled basins that crosses the plateau from northeast to southwest. The largest of the valley's basins is the 100-mile-long T'ai-yüan Basin. North of T'ai-yüan are three detached basins, which are areas of cultivation. Farther north the Ta-t'ung Basin forms a separate feature.

Drainage and soils. Several rivers drain eastward and southeastward, cutting valleys and ravines through the T'ai-hang and Wu-t'ai ranges, including the Hu-t'o and its tributaries. In the west several rivers cut across the Lü-liang Mountains and drain into the Huang Ho; principal among these is the Fen, which flows southward through two-thirds of the province. The northern mountains are drained chiefly by the Sang-kan, which flows eastward.

In the mountains, several types of light-brown and brown forest soils are common, with meadow-steppe varieties found at higher elevations. Alluvial soils in the central and southern portions of the province are formed mainly of calcareous (lime-bearing) brown soils deposited by the Fen River. There are also loess and lime deposits. Natural organic materials are not abundant, and salinity is excessive.

Climate. Shansi has a semiarid climate. The mean annual rainfall ranges from less than 10 inches (250 millimetres) a year in the northwest to a maximum of 20 inches in the southeast. Between 70 and 80 percent of the annual rainfall occurs between June and September. Temperatures range from a January mean of 19° F (−7° C) and a July mean of 75° F (24° C) at T'ai-yüan, to a January mean of 3° F (−16° C) and a July mean of 72° F (22° C) at Ta-t'ung. Winter droughts are common because the plateau is subject to the full force of the dry northwestern wind that blows in the winter from the Mongolian Plateau. In summer the southeastern monsoon (a rain-bearing wind) is blocked by the T'ai-hang Mountains. Hailstones are a common natural hazard, as are frequent floods, particularly along the course of the Fen.

Plant and animal life. Vegetation distribution primarily depends on the direction in which the mountain slopes face. The southern slopes are characteristically covered by species such as oak, pine, buckthorn, and honey locust, which are more tolerant of drier conditions than are the linden, hazel, maple, and ash that prevail on the more humid northern slopes. The province has long been cultivated, and such natural vegetation as remains consists mainly of shrubs and grasses; isolated forests occur on the north-facing slopes. Destruction of the original forest cover in ancient times eliminated most animal species.

The people. Most of the province's people are of Han (Chinese) origin and speak the Northern Mandarin dialect of Chinese. The small minority populations include the Hui (Chinese Muslims), in the T'ai-yüan–Yü-tz'u region, and some Mongols and Manchu around Ta-t'ung. Most of the populace lives in agricultural villages. The highest rural densities occur in the T'ai-yüan Basin, in the southeast around Ch'ang-chih, and in the Fen Valley.

Cities

The two principal urban areas are T'ai-yüan, the capital and leading industrial and mining complex, and Ta-t'ung, a mining and rail transport centre. Other manufacturing and transport centres include Yü-tz'u and Yang-ch'üan, both east of T'ai-yüan, and Ch'ang-chih in the southeast. Smaller cities are Ch'ü-wo (Hou-ma) and Lin-fen, both situated in the fertile Fen Valley; Fen-yang, immediately southwest of T'ai-yüan; and Yün-ch'eng, on the Hsieh Ch'ih salt lake in the southwest.

The economy. *Resources.* Shansi is China's major coal

region, producing one-quarter of the country's output. Proven reserves of anthracite and high-grade coking coal have supported the development of heavy industry and thermal generation of electricity. Iron ore is mined from vast deposits in the Ma-an Mountains district of central Shansi. The largest titanium and vanadium (metallic elements used in alloys such as steel) deposits in China are located near Fen-hsi. Other mined minerals include silver, zinc, copper, and edible salt.

Agriculture. Because of widespread erosion, only about one-third of the province is under cultivation. Extensive soil and water conservation efforts since 1949 have taken the form of terracing, afforestation, the digging of irrigation canals, diking of cultivated plots, soil desalinization, and land reclamation along rivers.

Agricultural production

In the extreme north the short growing season and long, cold winter limit cultivation to one annual crop of spiked millet, spring wheat, naked oats (oats with no covering on the kernels), potatoes, and sesame. In the rest of the province—except for the mountainous areas—the longer growing season permits three crops in two years or two crops in one year. Winter wheat, millet, soybeans, kaoliang (a variety of grain sorghum), corn (maize), and cotton are raised in adequately irrigated areas. Some tobacco and peanuts (groundnuts) as well as some fruits are produced in the central basins and on the Huang Ho floodplain.

Only a small part of Shansi's cultivated acreage is devoted to cash crops, such as cotton and sesame, the latter grown both for its oil seeds and for its fibre. Other cash crops include castor beans, rapeseed, and Indian hemp.

The relatively low ratio of population to land over much of Shansi's hilly terrain has traditionally fostered animal husbandry. Sheep are raised for their high wool yields. Domestic animals include pigs, horses, yellow oxen (for transport), donkeys, and chickens.

Industry. Most of the province's industries are concentrated in the T'ai-yüan–Yü-tz'u region. The iron and steel industry produces ingot steel, pig iron, and finished steel products. Heavy machinery, industrial chemicals, and chemical fertilizers are produced, as are cement, paper, textiles, milled flour, and wine. Other iron and steel centres include Yang-ch'üan, Ch'ang-chih, Ta-t'ung (which also produces cement and mining machinery), and Lin-fen.

Transportation. Shansi relies heavily on rail lines, both for intraprovince transport and for shipping raw materials, industrial commodities, and foodstuffs outside the province. The longest of these, the T'ung-p'u trunk line, runs from Ta-t'ung to Feng-ling-tu, in the southwest corner of the province. Additional branch lines connect the main line with newly opened industrial and mining sites. Major efforts have been made to relieve the pressure on Shansi's railways from ever-increasing freight volume and limited coal transport capability. Rail lines have been double-tracked and electrified, and trunk and spur lines have been constructed.

Long-distance, all-weather roads have been extended, especially near coal mines; many roads serve as feeder routes to the rail lines. The Fen River is navigable for small flat-bottomed boats as far north as Lin-fen. Freight traffic on the Fen, as well as on the north–south section of the Huang Ho, is insignificant, however.

Administration and social conditions. The chief provincial administrative body from 1967 to 1980 was the Shansi Provincial Revolutionary Committee. It was replaced in 1980 by the People's Government, which is the administrative arm of the People's Congress. The province (*sheng*) is divided into four prefecture-level municipalities (*shih*) and seven prefectures (*ti-ch'ü*). At the next lower level there are counties (*hsien*) and county-level municipalities (*shih*). An Office for Planning the Energy Resource Base of Shansi was established in 1982.

Education

The educational and medical institutions that were established in Shansi, mainly through foreign initiative, between 1898 and 1910 played a minor role in ameliorating the widespread poverty, illiteracy, and substandard health conditions that then prevailed. Shansi University, founded in T'ai-yüan by an English missionary in 1902, was one of the first in China to offer Western curricula in liberal arts, law, and medicine. Since 1949 technical schools for agriculture, mining, forestry, and machine technology have been established, as have universities, colleges, senior middle schools, and primary schools. The medical colleges and affiliated hospitals in T'ai-yüan offer treatment and full courses of study in both Western and traditional Chinese medicine.

Public works projects include a centralized water supply system based at Lan-ts'un that regulates the flow of the groundwater supply of the T'ai-yüan Basin, modernized sewerage and waste disposal facilities in the major cities, housing projects, and extensive "green belt" areas that are planted with thousands of trees.

Cultural life. Shansi's long-standing position as an avenue of communication between the North China Plain, the Mongolian steppes, and Central Asia gave rise to a rich and varied cultural and folkloric tradition. Several distinctive forms of Shansi opera became popular under the Ming and Ch'ing dynasties. Metalworking has been a specialty of Shansi craftsmen since the 2nd millennium BC. The province was also famous for the uniquely sculpted decorative tiles and glazed pottery figures used for temple decoration. The Chin-tz'u, near T'ai-yüan, is Shansi's best known temple complex; it was originally built in the 5th century AD. During subsequent periods it served as a monastery and as the centre for several religious cults.

Ancient handicrafts

HISTORY

Pollen analyses from western and southern Shansi reveal that several cereal plants were grown there as early as the 5th to the 3rd millennium BC. During the Hsi (Western) Chou period (1111–771 BC) the fief of Chin (now a colloquial and literary name for Shansi) was established in the area of modern Ch'ü-wo (Hou-ma) along the Fen River in the southwest.

Under the Han dynasty (206 BC–AD 220) Shansi assumed what was to become its traditional role as a buffer state between the pastoral nomads to the north and west and the sedentary Chinese farmers to the south and east. A predilection for political autonomy was paralleled by a commercial aggressiveness that led to the rise in the 18th and 19th centuries of a class of Shansi bankers and merchants famous throughout China.

From the end of the Han dynasty until the reunification of the empire under the Sui dynasty in 581, Shansi came under the dominance of several short-lived dynasties, most prominent of which was the Wei dynasty (AD 386–534/535) of the Pei-ch'ao (Northern Dynasties). Buddhism prospered for the first time during the Wei period; it was from Shansi that the Chinese Buddhist monk Fa-hsien began his legendary journey to India. The Buddhist cave sculptures dating from this period and preserved at Yün-kang today constitute some of China's most precious art treasures.

From the 7th century until the end of the 14th century, control over the area shifted back and forth among local military leaders, invading Turkic and Mongol forces, and representatives of the Chinese dynasty in power. Some stability was restored during the Ming dynasty (1368–1644).

Antiforeign feeling ran high during the latter years of the Ch'ing (Manchu) dynasty (1644–1911/12), despite the fact that there was relatively little foreign influence in the province. A few manufacturing establishments were set up in T'ai-yüan in 1898, and a French- and Chinese-financed railway between T'ai-yüan and Shih-chia-chuang in western Hopeh was built from 1904 to 1907. In 1900 antiforeign feeling took a violent form when an English mission church in T'ai-yüan was burned by the I-ho ch'uan (a secret society that came to be known as the "Boxers"), and foreigners and Chinese Christian converts were killed. This led to the outbreak of what became known as the Boxer Rebellion, which eventually spread to Peking.

Boxer Rebellion

After the overthrow of the Ch'ing dynasty in 1911/12, the Shansi warlord Yen Hsi-shan (1883–1960) ruled as an absolute dictator until the end of World War II. Yen was instrumental in establishing the nucleus of a heavy industrial base and in opening the T'ung-p'u railway in 1934.

During the Sino-Japanese War of 1937 to 1945, the Japanese developed coal resources in the T'ai-yüan Basin and expanded heavy industry. They were, however, con-

tinually harassed by Communist guerrillas who operated from mountain bases. The agricultural and handicrafts cooperatives established at these bases were instrumental in facilitating economic and social recovery after Communist forces assumed control of Shansi in 1949. (B.Bo.)

Shantung

Shantung (Shan-tung in Wade–Giles romanization, Shandong in Pinyin) is a north coastal province of China across the Yellow Sea from Korea. It has an area of 59,200 square miles (153,300 square kilometres). Shantung is China's third most populous province, its population exceeded only by that of Szechwan and Honan. The name Shantung means "Eastern Mountains" and was first officially used during the Chin dynasty in the 12th century.

The province consists of two distinct segments. The first is an inland zone bounded by the provinces of Hopeh to the north and west, Honan to the southwest, and Anhwei and Kiangsu to the south. The second is the Shantung Peninsula extending some 200 miles (320 kilometres) seaward from the Wei and Chiao-lai river plains, with the Po Hai (Gulf of Chihli) to the north and the Yellow Sea to the south, giving Shantung a coastline of 750 miles.

The inland zone, covering roughly two-thirds of the province's total area, includes a hilly central region, centred on the famous Mount T'ai complex, and a fertile and intensively farmed agricultural area on the north, west, and south, which forms part of the Huang Ho Basin and the North China Plain. The provincial capital, Chi-nan, is situated just west of Mount T'ai and three miles south of the Huang Ho, which flows from southwest to northeast through the province before emptying into the Po Hai.

Shantung Peninsula

The Shantung Peninsula, in contrast, is entirely an upland area and, with its seaward orientation and indented coastline, has traditionally depended on fishing, mining, and port-related activities. Long a focal area in the evolution of Chinese civilization and institutions, the province's natural inland–peninsular division is paralleled by a dual orientation in its past and present political and economic configurations. The eastern peninsula historically has coveted autonomy, whereas the inland portion has been closely tied to the inward-facing empire.

PHYSICAL AND HUMAN GEOGRAPHY

The hill regions

The land. *Relief.* Shantung is dominated by two hill masses to the east-northeast of the Grand Canal and to the south-southwest of the present course of the Huang Ho. These hills are formed mainly of ancient crystalline shales and sedimentary rocks on their flanks and of hard, very ancient rocks with granitic intrusions in their core. Both masses are detached remnants of China's most ancient geologic core. The easternmost (peninsular) mass is connected to the Liaotung Peninsula by a submerged ridge, emerging periodically in the Po Hai as the Ch'ang-shan Archipelago. In fairly recent geologic times, the Shantung hill masses stood as islands in an inland sea that separated them from the T'ai-hang Mountains of Shansi to the west.

A broad, marshy depression, the Chiao-lai Plain (sometimes known as Wei-hsien Valley), extends for about 100 miles from Lai-chou Bay in the Po Hai, south to Chiao-chou Bay in the Yellow Sea, near Tsingtao, and westward into the North China Plain. The generally flat surface of the plain is interrupted occasionally by bedrock-derived monadnocks, or residual rocks or hills, that have resisted erosion. Another depression, part of the inland zone of western Shantung, forms the central segment of the North China Plain. It slopes eastward into a northwest–southeast trough skirting the western perimeter of the central Shantung hill mass and is filled with a mixture of loess and alluvial materials (sand, clay, and gravel), along with more recently deposited alluvium, resulting from the building up of the Huang Ho floodplain. Five narrow lakes forming part of the Grand Canal system stretch out along this depression and are also linked to a series of saline marshes (indicative of earlier swamp conditions) that separate the fertile margin at the western edge of the central hills from the main sections of the North China Plain to the south and west.

Of the two main hill masses, the westernmost (inland) complex is the most extensive. It consists of a northern series of three parallel faulted ranges—the Hsing, Lu, and T'ai, which stretch northeastward for more than 200 miles—and a more diversified, lower, and more exposed southern portion. The granitic T'ai range, dominated by Mount T'ai, the most famous of China's five sacred mountains, attains a maximum elevation of 5,000 feet. The mountains of the peninsular mass to the east seldom rise above 700 feet. There, surface erosion has etched irregular and deeply cut valleys, and rounded hills contrast sharply with small intermontane basins. Both the north and south coasts of the peninsula are rocky, with hills dropping precipitously to the sea and separating a series of intensively cultivated crescent-shaped plains.

Drainage. Drainage is predominantly radial and subject to the prevailing configuration of the mountains. The only navigable river (other than portions of the Huang Ho) is the Hsiao-ch'ing, which emerges from a small spring-fed lake in a limestone outcrop zone near Chi-nan and flows parallel to the Huang Ho, before emptying into Lai-chou Bay. The southern hills, in contrast, are drained by several rivers in arable valleys, typified by those of the Tung-wen River system, which eventually terminate in the marshy plain east of the Grand Canal in Kiangsu Province.

Soils. The soils of Shantung fall into two broad categories associated with upland or lowland distributions.

Cable car carrying passengers to the top of Mount T'ai in Shantung Province.

Shantung brown soils

The so-called Shantung brown soils are found over most of the two major hill masses and include a variety of brown forest and cinnamon-coloured soils formed through clay accumulations and sod processes.

A distinctive variant of the typical Shantung brown soil is the recalcified soil (soil that has been made hard or stony by the deposit of calcium salts); it is found on the northern perimeter of the central hill mass. Calcareous alluvial soils predominate in both lowlands and plains. They are usually quite fertile, depending on both the length of time they have been cultivated and their proximity to urban centres (where heavier fertilization with human and animal wastes results in rich, dark-coloured soils). Silty alluvium covers most portions of the North China Plain area of the province.

The sandy ginger soil

Another distinctive soil type found in central and western Shantung on the North China Plain is the subsurface *sha-chiang t'u,* or "sandy ginger soil." This appears at the lowest elevations of alluvial plains where surface water remains unevaporated for several months until the dry season and also in sections of the plains subject to annual alluvial inundation. Such soils are always covered with alluvium or redeposited loess. Their name derives from the appearance of lime concretions that resemble the shape of ginger roots. Other *sha-chiang t'u* soils develop impervious layers of limestone hardpan.

Climate. Shantung falls within the North China climatic region, which extends from the Huai River in the south to the Hopeh–Liaoning border in the north. It is characterized by a continental climate with cold winters and hot, dry summers. Climatic variation prevails, however, between the peninsular and inland zones of the province.

The inland zone, especially in its northern sections, is subject to the full effect of the winter monsoon, when cold, northwesterly winds continue through December. By March wind direction gradually reverses, and warmer, southeasterly winds prevail throughout the summer. In the inland zone, annual precipitation ranges from 10 inches in northwest Shantung to 20 to 24 inches as one approaches the mouth of the Huang Ho. Of the total annual precipitation, 70 to 80 percent falls in summer. The interior areas of Shantung are also subject to severe winter and spring dust storms, sometimes followed by droughts and frequent summer floods. Temperatures in the inland zone range from a mean January reading of 25° F (−4° C) in the northern interior to a mean of 82° F (28° C) in July. This area is subject to freezing temperatures during one to three months, with frosts common from late October to April. Rivers often freeze over for extended periods during the winter months. In the interior zone the growing season extends 200 to 250 days.

Rainfall and temperature

The maritime orientation of the Shantung Peninsula tends to modify the climatic extremes of the inland zone. The northern half of the peninsula is subject to winter snow and rainstorms and to extensive coastal ice from the mouth of the Huang Ho to Wei-hai and Chefoo (Yen-t'ai); the southern half is somewhat warmer. Mean January temperatures range from 25° F (−4° C) on the northern coast of the peninsula to 32° F (0° C) in the south. There is less temperature difference during the hot summer months when the mean July temperature is 79° F (26° C), but the ports of Chefoo and Tsingtao are cooler than interior stations. Maximum summer temperature in these ports rarely exceeds 77° F (25° C). Sea fog is common along the north and south coasts of the peninsula. Because of the high relative humidity, annual mean precipitation over the peninsula reaches 31 inches, with less seasonal contrast than in the interior of the province. Heaviest precipitation occurs on the south-facing slopes of the central and peninsular hill masses.

Plant life. The limited natural vegetation that remains in the intensively cultivated inland zone of Shantung is found in minor depressions in the flat, alluvial landscape. Species there included reeds, grassy legumes, and several varieties of shrubs, notably tamarisk. Halophytic (salt-tolerant) vegetation is common in alkaline and saline soil areas along the coasts of the Po Hai and southern Shantung near the Kiangsu border. Many of the halophytic shrubs are harvested for fuel and are used for salt manufacture.

Halophytic plants

Lienliu, a shrub with long willowy branches, is used for basket weaving, while other plants are woven into thatch mattings and sunshades. Poplar, pine, and arborvitae (an aromatic evergreen tree of the cypress family) are planted around settlements, along roads, and on the coasts.

The mountainous zones of Shantung are almost completely deforested, with only a small part of the area covered by scattered deciduous and coniferous forests interspersed among barren, eroded hills. Several types of pine grow at higher elevations on rocky, shallow soils in association with alpine meadow species. On the lower slopes and in the valleys, mixed oak, elm, cedar, linden, ash, maple, and chestnut forests appear along with such economically important fruit trees as apple, pear, apricot, and peach. Other deciduous species found at the lower elevations include the pagoda (or Chinese scholar) tree, the white mulberry, Persian walnut, silk tree, and acacia. For centuries Shantung forests were overharvested for fuel and timber, and natural regeneration became extremely difficult. Since 1949, reforestation and closer regulation of timber harvesting has resulted in more extensive growth.

Despite the obliteration of much of Shantung's natural vegetation cover, the peninsular zone still exhibits an interesting mixture of northern and southern vegetation. Along with common northern plants, uniquely southern varieties, such as wingnut, magnolia, and styrax, are common.

Animal life. Through long periods of human settlement, intensive cultivation, and destruction of forests, animal life has suffered drastic decline. Animals include roe deer and field and harvest mice; birds include mandarin ducks, dollar birds (belonging to the roller group), and large owls. Even with recent attempts at reforestation, formerly extensive populations of native birds and mammals have almost vanished. Species of insects, beetles, and moths, however, are still unusually diverse and varied.

Settlement patterns. The two largest cities are Tsingtao and Chi-nan, followed by the Tzu-po conurbation, a leading mining and industrial zone at the northern edge of the central hill mass, about 20 miles east of Chi-nan. Other cities include Chefoo and Wei-hai, ports and fishing centres on the northeast coast of the peninsula; Wei-fang, an industrial and commercial town on the central Chiaolai Plain; and Hsin-t'ai, a mining town south of Tzu-pa.

Principal cities and towns

The greatest rural population densities are found in three areas. The first is one of the earliest settled places in the province, where irrigation works were constructed as long ago as the Han dynasty; it lies along the foothills of the central hill mass. The second, the southwestern Ho-tse–Ting-t'ao–Chi-ning area, is bounded on the northwest by the Huang Ho and on the southwest by the former course of the Huang Ho. This area was frequently subject to flooding, but because of its fertility and level terrain gradually became densely settled. The third area constitutes a fertile, irrigated strip along the north coast of the Shantung Peninsula between I-hsien and Lung-k'ou.

The people. Shantung's population is predominantly Northern Mandarin-speaking and of Han (Chinese) origin, but there are small concentrations of Hui (Chinese Muslims) in Chi-nan, the capital, in Chou-ts'un (near Tzu-po), and in Chi-ning and Lin-ch'ing (trading centres on the Grand Canal in western Shantung). The population, more than 90 percent rural, is fairly evenly distributed over the level, cultivated areas of the province.

The economy. Shantung has a diversified agricultural and industrial economy. A broad range of food and cash crops is grown for internal consumption and export to other provinces and overseas. The province's industrial base has been expanded since 1949. Before World War II, light industrial enterprises produced limited quantities of light products. Although the province often suffered a food deficit, agricultural products were continuously exported along with salt, coal, iron ore, and bauxite. Since 1949 relatively greater emphasis has been given to the development of industry, mining, and electric-power generation, although the absolute overall level of agricultural output has continued to rise. Shantung attained food self-sufficiency in 1970, while still increasing cash-crop production.

Resources. Shantung's industrial base is supported by extensive mining activities, principally coal mining, which

was originally developed by German concessionaires in the early 20th century. Considerable mechanization of coal-mining operations has taken place since 1949. There are also major iron-ore deposits located north of Tzu-po at Chin-ling-chen, some bauxite is mined near Nan-ting (Tzu-po), and gold is scattered throughout the peninsular hills. Edible salt is produced on both the north and south coasts of the Shantung Peninsula.

Oil and oil products have exerted an increasing influence on the economy of the province. The Sheng-li oil field, China's second largest continental oil production area, is located on the mouth of the Huang Ho in the Po Hai. The field yields a type of oil especially suitable for fuel. A lighter oil is produced at the Tung-p'u field, on the Shantung–Honan border. A pipeline completed in 1978 connects the Sheng-li oil field with those of the North China Plain in Hopeh and the ports and refineries of the lower Yangtze River area.

Major emphasis since the late 1970s has been given to increasing electric-power generation. High-voltage transmission lines and feeder lines to rural areas extend throughout the province and have substantially increased the supply of rural electric power, as well as the amount of electrically irrigated and drained acreage.

Agriculture. The success of agriculture in Shantung since 1949 is attributable to extensive investment in irrigation, flood-control, and soil-conservation measures; drainage of alkalinized and salinized land; and increased mechanization. More than 60 percent of the province's wasteland has been reclaimed and cultivated, and in most irrigated areas the productivity ratio has improved from three crops in two years to two crops in one year. The leading food crops—wheat, corn (maize), soybeans, kaoliang (a variety of grain sorghum), spiked millet, and sweet potatoes—account for most of the total cultivated acreage of the province. The remaining arable land is given over to cash crops, which contribute substantially to agricultural earnings.

Principal cash crops

Peanuts (groundnuts), the leading cash crop, are grown primarily in the peninsular uplands and in the south central sector. The large variety of peanuts grown in Shantung is especially well suited for oil pressing, and Shantung is a leading manufacturer of peanut oil for cooking. Shantung's other major cash crop, cotton, is grown throughout the province but is concentrated in the western and northern sections on the intensively irrigated lands near the mouth of the Huang Ho. Other cash crops include tobacco, grown chiefly on irrigated land in the vicinity of I-tu and Wei-fang; hemp, produced on low ground in the southwest; and fruit, grown on lower slopes of the central and peninsular hill masses.

Animal husbandry plays an important role. The most common animals are pigs, yellow oxen, and donkeys. Sheep are also raised in the uplands. Sericulture (silkworm raising), another important subsidiary activity, has been carried out in Shantung for hundreds of years. The popular fabric known as shantung was originally a rough-textured tussah, or wild silk cloth, made in the province. Silkworm raising is most common in the central hills near I-tu, Lin-ch'ü, Tzu-ch'uan, and Lai-wu, and most of the raw silk is sent to other provinces for processing and spinning.

Shantung's seaward orientation and its excellent harbours, as well as the convergence of cold and warm currents in offshore waters, have fostered a thriving ocean fishing industry, complemented by the intensive development of pisciculture in the province's western lake region. Trawlers and smaller fishing craft operate from ports around the peninsula and off the Huang Ho Delta. The ocean catch consists mainly of eels, herring, gizzard shad, fish roe, and several varieties of shrimp and crab. Freshwater varieties raised artificially are chiefly carp and crucian carp.

Industry. The province is still especially well known for its light industrial products, despite post-1949 gains in heavy industry. Tsingtao, the major manufacturing centre, has a large textile industry, a locomotive works, and chemical, tire, and machine-tool factories. Pre-World War II oil pressing (peanut oil), cigarette making, flour milling, brewing, and beverage distilling installations are still important. Chi-nan—long famous for its silks, precious stones, and handicrafts—now also manufactures trucks, agricultural machinery, machine tools, precision instruments, chemicals, fertilizers, and paper. Tzu-po produces glass, porcelain and ceramics, and textiles. Wei-fang is an important food-processing centre, and it also has metal-processing and textile factories. Some of Shantung's better known handicraft goods are embroidered tablecloths from Chefoo and Lin-tzu, straw braids for hat weaving from P'ing-tu (east of Wei-fang), poplins, pottery, and ceramics.

Light industry and handicrafts

Transportation. Shantung's earliest railways were built in the first decade of the 20th century during the time of the German concession. One of the lines traverses the province from north to south and another east to west, connecting Tsingtao and Chi-nan. Since 1949 new lines have been built, including a major trunk line from Tsingtao north to Chefoo.

Shantung's highways connect every district in the province, but many of them have earthen surfaces and are used either for short-haul transport or as feeder routes for the major railways. Truck traffic accounts for a majority of the total annual vehicular movement over Shantung's highways, as compared with only a small proportion in other North China provinces.

Limited use of inland waterways

Except for portions of the Huang Ho and of the Hsiao-ch'ing River in northern Shantung, part of the Grand Canal in the west, and the I River in the southeast, inland-waterway transport is limited. The chief route—for shallow-draft craft only—extends upstream from Li-chin, about 50 miles inland from the mouth of the Huang Ho, to Ch'i-ho, the main Huang Ho river port in Shantung and just northwest of Chi-nan. The Grand Canal is navigable only to a limited extent south of the Huang Ho.

Shantung has a number of excellent seaports. Tsingtao is the largest in tonnage handled, although Chefoo, Wei-hai, and Lung-k'ow on the north coast of the peninsula also handle a considerable amount of shipping. Coastal shipping also plays an important role in Shantung's economy. Tsingtao alone handles more than one-third of the province's intraprovince trade. Trade between Tsingtao and Shanghai and Tsingtao and Lü-ta is particularly heavy.

Administration and social conditions. *Government.* Shantung is divided into six prefectures (*ti-ch'ü*) and eight prefecture-level municipalities (*shih*). At the next lower administrative level there are counties (*hsien*) and county-level municipalities (*shih*). The Shantung Provincial Revolutionary Committee, the chief provincial administrative body from 1967, was replaced in 1980 by the People's Government, which is the administrative arm of the People's Congress. Until the early 1980s the rural people's communes, made up of production teams and brigades, served as the lowest administrative units. With the institution of family farms as primary production units, commune labour allocation, production, and marketing became less important. In many areas, county seats operate as coordinating centres for the production and distribution of commodities produced in the areas under their administrative jurisdiction.

Higher education complex in Chi-nan

Education. Most of Shantung's institutions of higher education are located in the provincial capital, Chi-nan, with smaller or special-purpose schools scattered widely throughout the province. Among those in Chi-nan are the Shantung Medical College and the Shantung Institute of Technology. Shantung University is in Tsingtao. Tsingtao is China's major centre for research training in marine science and technology. Institutions include the Institute of Oceanology of the Academia Sinica (Chinese Academy of Sciences) and the Shantung Oceanography College, which is under the jurisdiction of the national-level Ministry of Education.

Health and welfare. Before 1949 Shantung was particularly hard-pressed by the pressure of population on the land, by the common occurrence, especially since the latter half of the 19th century, of floods, droughts, dust storms, excessive soil salinization and alkalinization, and insect infestations, and by frequent military and civil disturbances. Few serious attempts were made by officials of either the Ch'ing (Manchu) dynasty (1644–1911/12) or, later, by the Republic of China to ameliorate the difficult social conditions of the peasant population. With the ex-

ception of missionary-financed and missionary-controlled undertakings in areas under foreign influence or administration, such as Tsingtao, Chefoo, and Chi-nan, modern intensive health-care facilities were virtually nonexistent, and there was only token support for public higher education. Water supplies, environmental sanitation facilities, and public housing were similarly inadequate to the needs of the populace, and public health services were neglected and understaffed.

Since 1949 the public health services in both rural and urban areas have been improved, and formerly common ailments such as kala-azar (a severe infectious disease transmitted by the sand fly), leprosy, and a variety of nutritional-deficiency diseases have been eliminated. Most large and medium cities now have adequate water-supply systems, often built in conjunction with multipurpose water-conservancy schemes to improve and stabilize the watersheds of nearby rivers. Along with water supply, the construction of sewage treatment facilities in many cities has also helped raise public-health standards.

Multi-purpose systems of water supply

Not only has extensive tree planting enhanced the beauty of most Shantung cities, but "greening" has been officially designated as a primary task of urban reconstruction in order to ameliorate the effects of harsh climates and to improve health conditions. In Tsingtao alone, some 4,000,000 trees were planted from 1949 to 1959, while in Chi-nan, a green belt has been built on the site of some dilapidated sections of the ancient city wall. Along with urban reforestation, recreational facilities have been expanded, improved, and made readily available for public use. Many famous temples, hot springs, shrines, parks, lakes, and museums are frequented by the populace. In Chi-nan, a city famous for its hot springs, where for centuries poets, scholars, and officials enjoyed diverse pleasures, several new parks have been built and old buildings restored. Tsingtao, known as the most pleasant beach resort in North China, is also famous for its parks.

Cultural life. Shantung's rich cultural and folklore tradition is most clearly evidenced in the temples, shrines, legends, and cults associated with Mount T'ai and with the temple and tomb of Confucius at Ch'ü-fu, north of Chi-ning. Despite official disavowal from 1949 until the mid-1980s of their religious, parareligious, animistic, and superstitious connotations, the temples, shrines, and their surrounding areas have been restored, renovated, and converted to public parks so as to assure their preservation as important symbols of the national cultural heritage.

Mount T'ai

Mount T'ai—known also as Tung-yüeh, or "Eastern Peak," to distinguish it from the "Southern Peak" (in Hunan), the "Central Peak" (Honan), the "Western Peak" (Shensi), and the "Northern Peak" (Shansi)—is the most prominent of these five sacred mountains where the emperors once offered sacrifices to Heaven and Earth. It was also the place where for centuries Buddhists, Taoists, and Confucianists built more than 250 temples and monuments to honour deified historical personages and to immortalize the sacred presence and supernatural powers of the supreme mountain deity of Mount T'ai. The mountain was deified at least as early as Han times, and in the Sung dynasty it was elevated by the emperor Chen-tsung to the position of "Equal with Heaven." Incantations and prayers offered to the deity of Mount T'ai by countless emperors are inscribed in stelae along the ascent to the summit, and temples are distributed in T'ai-an and on the mountain itself.

The Temple of Confucius, Confucius' tomb, and the residence of the Kungs (Confucius' lineal descendants) at Ch'ü-fu are also maintained as national historic monuments. Both the temple and the Kung residence are laid out with elaborate temples, monuments, pavilions, and gates, and have collections of stelae dating, in some cases, from the Han dynasty.

HISTORY

A Neolithic culture—known as the Lung-shan because of archaeological remains discovered near the township of that name—existed on the Shantung Peninsula in the 3rd millennium BC; it played a key role in the establishment of a common rice-based cultural grouping that apparently spread along the Pacific seaboard from the peninsula to Taiwan and eastern Kwangtung.

Western Shantung formed part of the Shang kingdom (18th–12th century BC). By the Ch'un-ch'iu (Spring and Autumn) period (770–476 BC) it had become the centre of political and military activity that resulted from the eastward expansion of the Chou, following their conquest of the Shang. One of the small southern Shantung states was Lu, the birthplace of Confucius and Mencius. Also in the "Eastern Territory"—an early name for Shantung—was Ch'i, extending over the major part of the peninsula; it became an important economic centre, exporting hemp clothing, silk, fish, salt, and a unique variety of purple cloth to all parts of China. Beginning in the Six Dynasties period (AD 220–589), Shantung became North China's leading maritime centre, receiving commodities from the South China coastal area (now Fukien and Kwangtung) for transshipment to destinations north and south of the Huang Ho. Thus, Shantung has been a part of China from its very beginning as an organized state.

Grand Canal

In 1293 the Grand Canal, running generally north to south, was completed, making western Shantung a major inland trading route. Yet even after the completion of the canal, maritime trade still remained important to Shantung, and the peninsula retained its dominant economic position. In the great agricultural areas of the province, however, early deforestation and the long-established practice of clearing land for cultivation without providing for flood prevention and control measures led to serious and ultimately disastrous erosion and wastage of valuable agricultural land.

In the 19th century these problems were worsened by shifts in the course of the Huang Ho. From 1194 until the early 1850s the Huang followed the original bed of the Huai along the Shantung–Kiangsu border before emptying into the Yellow Sea. After 1855, when a series of devastating floods was followed by extensive dike construction, the river changed to its present course some 250 miles to the north. Hardships and food shortages from floods and other natural calamities increased in intensity throughout the 19th and 20th centuries. This resulted in a substantial emigration of Shantung peasants to the Northeast (Manchuria) and to Inner Mongolia, with more than 4,000,000 people emigrating between 1923 and 1930.

In the closing decade of the 19th century Shantung came under the influence of German, British, and Japanese interests. It was occupied briefly by Japanese troops after the Sino-Japanese War of 1894–95. In 1897 Germany landed troops, and in 1898 a treaty was signed by which China ceded to Germany, for 99 years, two entries to Chiao-chou Bay and the islands in the bay and granted the right to construct a naval base and port, Tsingtao. Germany used Tsingtao as a base to extend its commercial influence throughout the peninsula; it developed coal mines and constructed a railway (1905) from Tsingtao to Chi-nan. Similarly, in 1898 Great Britain obtained a lease for Wei-hai-wei (modern Wei-hai), another strategic port near the northern tip of the peninsula. This was in response to the Russian occupation of Port Arthur (now Lü-shun). With the advent of World War I, Japan took over German interests in the peninsula and in 1915, as one of its infamous 21 Demands, compelled the Chinese to give official recognition to the renewed occupation. Taking up the Shantung question, the imperialist powers decided in 1919 to grant Japanese occupation, which Japan maintained until 1922.

In the Sino-Japanese War of 1937–45, even though the Japanese had gained control of most of Shantung by the end of 1937, they miscalculated Chinese strength and suffered a serious defeat—their first of the war—at T'ai-erh-chuang, in southern Shantung, in 1938. In the postwar struggle between the Chinese Communists and Nationalists, Shantung came under Communist control by the end of 1948.

Tientsin

For coverage of Tientsin, see the *Macropædia* article TIENTSIN.

LOWER YANGTZE VALLEY

Anhwei

Anhwei (An-hui in Wade–Giles romanization, Anhui in Pinyin), one of the smallest provinces of China, covers an area of 54,000 square miles (139,900 square kilometres) and stretches for 400 miles (640 kilometres) from north to south. Anhwei, which is landlocked, is bounded by the provinces of Kiangsu to the northeast, Chekiang to the southeast, Kiangsi to the south, and Hupeh and Honan to the west. Its northern extremity barely touches the southern extremity of Shantung. Its name means "beautiful peace" and is derived from the names of two cities—An-ch'ing and Hui-chou (now She-hsien). The capital, Hofei, is located in the heart of the province. Anhwei was long one of China's poorest and most undeveloped areas. Since 1949, however, successful attempts have been made to utilize the province's economic and human resources. Vast irrigation schemes on the major rivers have alleviated severe periodic flooding and have also provided increased agricultural land and electric power.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Anhwei lies in the path of the Neo-Cathaysian Geosyncline (a great downward flexure of the Earth's crust), which stretches across the entire length of eastern China from Heilungkiang on the Soviet border to Kwangsi on the Gulf of Tonkin. The floor of the geosyncline is steadily sinking under the weight of the silt carried by the Huang Ho (Yellow River) and the Huai River. The sediment is estimated to be more than 2,000 feet (600 metres) deep.

Relief. The northern portion of Anhwei Province is occupied by the North China Plain—an immense level surface that has periodically been flooded by its dominant rivers. The southern section of the province, the Yangtze Valley, is separated from the northern plain by a series of mountains that stretch roughly from west to east. The Ta-pieh Mountains—an extension of the Tsinling–Fu-niu ranges lying to the north of the Yangtze—form a convex curve of steep slopes facing east and northeast on the southwestern Hupeh–Anhwei border. The Paichi Mountains lie south and east of the Yangtze and form the southeastern border between Anhwei and Chekiang. Composed mainly of granite, metamorphic rock (rock formed in the solid state by heat and pressure), and sandstone, they include the Huang Mountains, a range that rises to a height of 6,000 feet and is beloved by poets and artists for its massive shape and lush vegetation.

The Huai and Yangtze river basins

Drainage. The northern plain is drained by the Huai River. Its many left-bank tributaries rise in the western mountains and flow eastward across Honan Province into Anhwei. The shorter right-bank tributaries rise in the Ta-pieh Mountains. The Huai flows across the level plain and drains into Hung-tse Lake, which lies just across the eastern border with Kiangsu Province. The river basin is subject to widespread and disastrous floods.

The watershed between the Huai and the Huang to the north is barely perceptible. At least three times the Huang Ho has changed its course to flow south of the Shantung Peninsula, joining its waters with the Huai to flow into the Yellow Sea. Because of its susceptibility to disastrous floods, the Huai Basin was chosen in 1949 to be the site of the first large-scale water-conservation project to be undertaken by the People's Republic. The scheme entailed building several dams on the upper reaches of the Huai and its tributaries in order to control the flow of floodwaters, constructing or rebuilding hundreds of miles of dikes and irrigation and drainage canals along the main rivers, clearing the entry to and the exit from Hung-tse Lake, and digging the Su-pei Canal from the eastern edge of the lake to the Yellow Sea. Since 1956 there have been no serious inundations, local flooding has been controlled, and irrigation has successfully compensated for threatened drought.

The low line of hills (Hua-yang Mountains) that extends northeast from the Ta-pieh range to Hung-tse Lake marks the divide between the Huai and Yangtze river basins. The Yangtze plain is studded with lakes that, in time of flood, join the river and increase its width in places to five miles. The change of river level between summer and winter is not as great as it is in Hupeh; nevertheless, winter navigation is difficult. The Yangtze plain is crisscrossed by canals that are used for irrigation, drainage, and transport.

Soils. The province's complex soil structure can be divided broadly into three categories. The uplands to the north and south of the Yangtze are mainly podzolized (leached) old and young red earths that are susceptible to erosion but are valuable for the cultivation of tea. The Yangtze floodplains are composed chiefly of alluvium and rice-paddy soils that have a slightly acidic character. The alluvial soil of the Huai Basin—particularly the area drained by the left-bank tributaries and extending into the North China Plain—is, however, calcareous (chalky). It includes curious mineral masses that are known as *shachiang t'u* ("sandy ginger soils") because they resemble ginger roots. They form in low-lying places where the ground is waterlogged, rarely occur on the surface, and sometimes form a hardpan, or basin, some feet below ground level.

Climate. Anhwei shares with much of the rest of China the seasonal monsoon climate characterized by hot, wet summers and cooler, dry winters. As it extends for about 400 miles from north to south, however, Anhwei experiences appreciable variations in climate. Mean January temperatures in the north of the Huai Basin range between 32° F (0° C) and 36° F (2° C). Mean July temperatures in both regions are 82° F (28° C). The north has between 200 and 230 frost-free days, while the south experiences between 230 and 250. The relative humidity is considerably higher in summer in the Yangtze Valley than in the Huai Basin. Northern Anhwei experiences some discomfort when winter dust storms, brought by bleak winter winds, sweep down from the Shansi Plateau.

Rainfall distribution

There is a marked difference between the rainfall of the Yangtze Basin and that of the Huai plain. In the south the precipitation amounts to between 47 and 71 inches (1,200 and 1,800 millimetres) and is relatively evenly distributed. In the north the mean annual rainfall is between 24 and 31 inches, more than half of which falls between June and September. Rainfall becomes progressively unreliable as one progresses northward until the famine lands of the northwest are reached. Summer evaporation in northern Anhwei is intense.

Plant and animal life. The original vegetation was forest and woodland, but centuries of intensive settlement have led to deforestation everywhere except in the western and southern uplands. This process, accompanied by soil erosion, has been very rapid since the mid-18th century. Cultivated crops and grass have replaced the trees, but fuel gatherers annually strip the hillsides of grass. The only remains of the forests on the plains are the bamboo groves and woods surrounding temples and villages. Since the 1950s, resolute efforts at afforestation have been made, and fuel gathering has been restricted.

One of the world's rare animals, the Yangtze alligator, lives in the environs of Wu-hu. It is less than six feet long and feeds mainly on fish and small animals. Apart from rodents and reptiles, very few wild mammals remain in the densely settled and cultivated plains.

Population distribution

The people. The regions of densest population are the tributaries and banks of the Huai above Pang-pu and the diked areas along the right bank of the Yangtze. Generally, the villages in the Huai Basin are somewhat larger than those in the south. In the Yangtze Valley, villages are farther apart, and there are more scattered homesteads. Population density is considerably less in the hilly region that separates the two river basins, with the lowest densities in the southern uplands.

As in the rest of China, there is no precise demarcation between rural and urban population. Places of 2,000 people and fewer that are essentially engaged in agriculture

Rural homestead in a village near T'un-hsi in southern Anhwei Province.

are classified as rural. There are four large towns—Ho-fei, the capital; Huai-nan; Pang-pu; and Wu-hu. Towns of lesser importance are An-ch'ing, the former provincial capital; Ma-an-shan; and Ta-t'ung. Since 1954 many of these towns have grown rapidly because of industrialization, and new towns have also appeared.

The population is almost totally Han (Chinese), and there are no pockets of aboriginal peoples as there are in the provinces south of the Yangtze. Until the 7th century AD there were large numbers of Hakka, but they were later driven south into Fukien and Kwangtung. Those of their descendants who remain have been integrated with the main body of the Chinese population.

The economy. Until 1949 Anhwei was regarded as the most backward province of eastern China. Most of its population was rural, and the standard of its agriculture was low because of poor use of water resources. Mineral resources were little developed. Since the 1950s there have been great advances in agriculture and industry. Improvements in irrigation now allows more land in the south to be double cropped in rice; and other water conservancy and land improvement measures and a return to household farming have improved yields and increased per capita net farm income. The Shanghai special economic zone, established to promote industrial growth, includes Anhwei Province, and long-range planning envisage the development of Anhwei's mineral resources on the model of the Ruhr Valley in West Germany.

Agriculture. Wheat is the predominant crop in the Huai Basin to the north, and—more importantly—rice is grown in the Yangtze Basin to the south. In the relatively wetter Yangtze Valley well over half of the cultivable land is devoted to rice, while in the drier Huai Basin about one-third of the land is under wheat. Most of the land produces two crops a year. Anhwei is also one of China's most important soybean producers; the beans are grown mainly in the north in rotation with wheat or barley. Increasing amounts of kaoliang (a variety of grain sorghum) and millet are also grown in the north. The main industrial crops are vegetable oilseeds, cotton, tea, fibres, and tobacco. Among the vegetable oils, the most important are rapeseed, peanut (groundnut), and sesame. Cotton is grown mainly on the northern Huai plain. Hemp, jute, and ramie (an Asian nettle that yields a fibre used for making textiles) are also grown.

Tea and silk cultivation

Anhwei has been famous for its tea since the 7th century, when teas were exported to the rest of China, as well as abroad. This trade became depressed in the late 19th and early 20th centuries but has now revived; Keemun black tea is especially famous. The main areas of cultivation are on the slopes of the Ta-pieh Mountains, north of the Yangtze, and on the Paichi Mountains along the Anhwei–Chekiang border. Sericulture, the production of raw silk by the raising of silkworms, has also been revived since the 1950s. During the years of warfare from 1937 to 1949, many of the mulberry trees were felled to deprive guerrilla forces of cover. These have been replaced, and both the mulberry-feeding moth (*Bombyx mori*) and the tussah silkworm are reared, providing the raw material for Nanking brocades and Wu-han silk fabrics.

Large domesticated animals are used almost exclusively for draft purposes. Pigs are the main source of meat, and sheep are raised in increasing numbers in northern Anhwei. Numerous rivers and lakes abound in fish, mainly carp and white bream. Fish are bred all along the Yangtze.

Industry. Anhwei's industrial development was quite limited before the 1950s, based mainly on the partial development of its rich copper, iron, and coal deposits. In the 1950s there was substantial development of the Huai-nan coal basin—first worked in the 1920s—followed in the 1960s by the development of the Huai-pei basin. This coal is the primary source of power for Anhwei's mainly thermally generated electricity supply, although hydroelectric power units on tributaries of the Huai supply the province's major industrial centres. Anhwei is also rich in high-quality iron ore, located near the Kiangsu border. These reserves, first developed by the Japanese during World War II, were further developed in the 1950s. A large copper shaft mine and smelter were built at T'ung-ling in the 1950s on the site of a T'ang dynasty copper lode, and T'ung-ling developed into a major supplier of blister copper.

The capital, Ho-fei, is the province's major industrial centre; its development began in the 1950s with the transfer of a number of textile and light industry plants from Shanghai. In the 1960s steelmaking and machine-tool plants were established to serve provincial mining, electrical, and chemical industries, and the city also developed into a producer of chemical fertilizer. Pang-pu, in northern Anhwei, has developed into an important supplier of agricultural machinery and a major food-processing centre. Wu-hu, on the southern bank of the Yangtze, has been a commercial centre since the 1960s, with a port that plays an increasingly important role in both domestic and international trade.

Transportation. Throughout the centuries waterways have been the main means of communication. Water-conservation schemes have increased the navigability of rivers and canals, and traffic on them is heavy. The ports of Ma-an-shan, Wu-hu, T'ung-ling, Ta-t'ung, and An-ch'ing on the Yangtze can be reached by oceangoing vessels of 15,000 tons during the high-water summer months. The principal railway in Anhwei enters the province from Suchow across the northern Kiangsu border and runs south to Pang-pu, where it divides—the main line running southeast to Nanking in Kiangsu Province, and a branch line running south to Ho-fei, from where it runs southeastward to the Yangtze opposite Wu-hu. Ho-fei stands at the centre of the province's highway system, with main roads running to Nanking, Pang-pu, and Wu-han.

Administration and social conditions. *Government.* From 1950 to 1954 Anhwei was included in the East China greater administrative region, which embraced all the east coast provinces from Shantung to Fukien. In 1954 provincial (*sheng*) government was made directly subordinate to the national government. Anhwei is subdivided into eight prefectures (*ti-ch'ü*) and eight prefecture-level municipalities (*shih*). Below this level it is divided into counties (*hsien*) and county-level municipalities (*shih*). The provincial Revolutionary Committee appointed by the central government during the Cultural Revolution was replaced in 1980 by the People's Government, which is the administrative arm of the People's Congress.

Education. Western learning was introduced in the early decades of the 20th century through the teaching of Christian missions. The National Government after 1928 attempted to expand education throughout the province, but most people remained illiterate. After 1949 the prob-

Role of the communes in education

lem of illiteracy was attacked with vigour. The communes established in the late 1950s were then made responsible for primary and middle-school education, and a program combining work and study was introduced. On the slopes of the Ta-pieh Mountains, several schools of sericulture have been established; and the tea-growing regions now have special schools for farming and study. Despite considerable advances in education, however—Anhwei has some 50,000 primary and secondary schools and more than 30 colleges and universities—only about two-thirds of the adult population is literate.

Health and welfare. Medical and health services that were developed after 1949 were at first concerned primarily with public hygiene and preventive medicine. Medical teams were sent into the countryside to inoculate the population and to teach and advise on matters of public health. From 1960 hospitals were built in the communes and all the major towns. The emphasis on public hygiene has, however, been maintained. Both Western and traditional medical practices are employed.

Cultural life. The Anhwei region was one of the earliest areas in the Yangtze Basin to be settled by Sinitic peoples. Many of the current linguistic and cultural traits of the region were shaped during the Nan (Southern) Sung period (1127–1279), particularly the characteristic conservatism of language and art forms. A number of separate regional subcultures continue to exist, including the Hui-chou culture from the region around She-hsien, renowned for its commercial and clan traditions.

HISTORY

During the Chan-kuo (Warring States) period of the Chou dynasty (475–221 BC) Anhwei formed part of the large southern state of Ch'u. Between 221 and 206 BC the Ch'in dynasty unified the states, and a great southward migration along the natural highway of the North China Plain and the Huai River basin began. Anhwei became the first part of southern China to be settled by the Han. Unrest following the fall of the Han dynasty in AD 220 led to further immigration into the area.

Growth under the early canal system

The Yangtze River basin subsequently became the granary of the empire, and an improved transport and canal system was developed across northern Anhwei to carry tribute grain to the capital from Su-chou to Pien (modern K'ai-feng) in Honan and from there to Lo-yang in Honan. It was later superseded by the New Pien Canal, built during the Sui dynasty (581–618). The new canal ran along the Kuei River and then cut across the region to Pien, forming the main line of communication to the capital. During the 12th century Anhwei was the scene of bitter battles between the Nan Sung emperors and the invading Juchen. After the establishment of the capital at Ta-tu (modern Peking), the Yüan, or Mongol, dynasty (1206–1368) constructed the Grand Canal to the east, connecting Hang-chou in Chekiang Province with Ta-tu, and the previously built waterways fell into disuse.

In the early 1850s the Huang Ho made one of its great changes in course, flowing into the Po Hai, north of the Shantung Peninsula instead of south into the Yellow Sea. The loss of water for the Huai Basin resulted in great distress for the farmers of northern Anhwei. Subsequent peasant risings—together with the Taiping Rebellion of 1850–64—resulted in widespread devastation.

The Yangtze was opened to foreign shipping in 1860, but it was not until 1877 that the walled city of Wu-hu in Anhwei was opened to international trade. Although it was the province's only treaty port, the city never figured prominently in overseas commerce.

In 1938 the Huang Ho was temporarily diverted south of Shantung by the Nationalist government, which blew up the river's dikes in Honan in an attempt to stem the advance of Japanese invaders. The river waters then surged south to Hung-tse Lake on the Anhwei border, flooding an enormous area at the cost of about 900,000 lives. During World War II most of Anhwei was occupied by Japanese forces, but, because of the resistance of the Chinese inhabitants, Japanese control could be effectively enforced only during daylight hours. Between 1946 and 1949 the province was controlled by the Nationalist forces.

From 1949 to 1952 Anhwei was administered in two separate parts. The section north of the Yangtze, which came under Communist military control in 1949, was constituted as the North Anhwei Administrative District. The South Anhwei Administrative District was established several months later, after the People's Liberation Army (PLA) crossed the Yangtze and based its administration in Wu-hu. In August 1952 the province was reunified under the leadership of Zeng Xisheng (Tseng Hsi-sheng), a long-time veteran of the PLA. Anhwei's provincial administration experienced relatively greater leadership turnover than other provinces in the 1950s and '60s and a major shift in leadership during the Cultural Revolution. During the 1970s Anhwei supported many of the radical programs of the Cultural Revolution, but in the late 1970s the province became a base for many of the moderate reforms advocated by the post-Mao leadership.

(T.R.T./V.C.F./Ed.)

Hupeh

Hupeh (Hu-pei in Wade–Giles romanization, Hubei in Pinyin) Province lies in the heart of China and forms a part of the middle basin of the Yangtze River. Until the reign of the great K'ang-hsi emperor (1661–1722) of the Ch'ing dynasty, Hupeh and its neighbour Hunan formed a single province, Hukuang. They were then divided and given their present names: Hupeh, meaning, "North of the Lakes" (of the Yangtze River); and Hunan, "South of the Lakes." Hupeh has an area of 71,800 square miles (185,900 square kilometres). Its capital is Wu-han, the composite name of the three cities of Han-k'ou, Han-yang, and Wu-ch'ang, which lie at the confluence of the Han River and the Yangtze at a point approximately 600 miles (1,000 kilometres) from the sea and halfway between Shanghai and Chungking.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Almost all of Hupeh Province lies immediately north of the Yangtze River. Hupeh is bounded on the north by the eastern extension of the axis of the Tsinling, T'ung-pai, and Ta-pieh mountains. In the southeast the Mu-fu Mountains divide the province from Kiangsi. Along its central southern border there is no clear physical divide apart from the Yangtze itself: a lake-studded alluvial plain continues uninterruptedly southward to Tung-t'ing Lake in Hunan. The Wu-ling Mountains form the boundary between southwest Hupeh and northwest Hunan. Western Hupeh has highlands that lie at an altitude of more than 6,000 feet (1,800 metres) and consist of the eastern extension of two ranges, the Ta-pa and Fang-tou mountains, marking the boundary between Hupeh and Szechwan.

The level of the land falls rapidly, from west to east, to the lake plain, much of which is no more than 200 feet above sea level. This flat or gently undulating country is often suddenly interrupted by steeply rising isolated hills or ranges. The plain is the remnant of a former depression or old lake basin formed in the Pliocene Epoch (from 7,000,000 to 2,500,000 years ago), which has largely been filled with eroded red sandstone from Szechwan. The process of filling in is not yet complete; in consequence, large areas adjoining the Yangtze and Han rivers are covered by innumerable shallow lakes.

Rivers

Drainage and soils. The Yangtze cuts its way from the Szechwan Basin through the Ta-pa Mountains in a series of magnificent gorges and descends rapidly to the Hupeh Plain at I-ch'ang. The bed of the river at I-ch'ang is only 130 feet above sea level and is 960 miles from the sea. From this point onward its velocity decreases and its bed widens as it winds its way across the province from west to east. Finally, it forces a passage between the Mu-fu and Ta-pieh ranges into Anhwei and Kiangsi provinces. There the river again narrows to less than half a mile in width. In its course through Hupeh the Yangtze receives the waters of two tributaries, the Han and the Ch'ing rivers. It also receives, through Tung-t'ing Lake, the entire drainage of Hunan. The Han, itself a considerable river even by Chinese standards, rises in the Tsinling Mountains and

flows eastward in Shensi Province for about 200 miles. On entering Hupeh, it turns south in a much broader valley, or floodplain, and widens its bed, which varies from half a mile to a mile in width over much of this stretch. About 100 miles from its confluence with the Yangtze at Han-k'ou (*k'ou*, "mouth"), it turns east, threads its way through a maze of lakes, and, in the last few miles, narrows its bed to a mere 250 yards—a factor that is responsible for much flooding in summer.

The variation in the regime of the Yangtze between summer and winter is striking. At Han-k'ou, where the river is nearly a mile wide, the average difference between summer and winter levels is 45 feet. In winter the river is sluggish, with many shallows, and is navigable up to Han-k'ou only by specially built flat-bottomed river steamers. With the coming of the spring and summer rains the change is dramatic, and the river comes down as a mighty flood. In times of exceptional flood, as in 1931 and 1954, the flow reaches astronomical figures. Flooding of large areas of the surrounding low-lying land is normal each summer, when river and lakes combine. Marco Polo, who visited the area in the 13th century, reported that in places the river was more than 10 miles wide; his report was discredited as a gross exaggeration, but he had seen the Yangtze in the summer flood. In summer Han-k'ou is an ocean port, capable of receiving vessels of 10,000 to 15,000 tons. There are, however, navigational hazards at this time. Great care has to be taken that a vessel does not stray from the true river course and become grounded in more shallow water. If this happens, refloating is an urgent matter as the river is prone to quite rapid falls in level, and the vessel may be left stranded for a year.

Hupeh lies in a neutral soil zone between the pedocals (soils of arid or semiarid regions, enriched in lime) of North China and the pedalfers (soils of humid regions, enriched in alumina and iron) of the South. The uplands are mainly brown mountain earth, the lower hilly lands yellow-brown soil, and the lowlands alluvium and red earth.

Climate. Hupeh's rainfall follows the general Chinese seasonal pattern, governed by the rain-bearing monsoon winds. Han-k'ou has an average minimum rainfall of about an inch (25 millimetres) in December and a maximum of almost 10 inches in June, with a total annual fall of about 50 inches. Rainfall throughout the province decreases from southeast to northwest. Much of this rainfall is caused by cyclones, which pass down the Yangtze Valley from west to east. Occasionally, such as in the summer of 1931, a series of cyclones passes down the valley in rapid succession, bringing phenomenal rainfall and disastrous flooding. Since 1949 considerable effort has been directed toward flood control measures in the valley.

Cyclones

Hupeh winters, although usually short, are often rigorous, with heavy and glazed frost and some snow brought by bitter north winds in January and February, when the average temperatures are 40° F (4° C) and 43° F (6° C), respectively. Summers are hot, with July temperatures averaging 85° F (29° C), and are long and oppressive because of the high relative humidity. Any light breeze by day tends to die out in the evening, leading to intolerable nights when mothers bring their bamboo beds into the streets and sit fanning their children through the weary hours. There are about 270 frostless days in the south and 250 in the north.

Plant and animal life. The natural vegetation of Hupeh is dense forest, but this was cleared from the lowlands and hills many centuries ago, leaving only the western highlands densely wooded. The forests and woodlands consist mainly of *ma wei* (pine), *shu mu* (cedar), camphor, yellow sandalwood, maple, and poplar. As a result of deforestation, soil erosion has been serious. Despite sporadic efforts to plant the hillsides with trees during the early decades of the 20th century, the poverty of the people and the demand for fuel led to the continued stripping of trees. Since 1949 there has been a determined effort at afforestation and its maintenance.

There is a sparsity of large wild animals. Some small barking deer are found in the scant cover on the hills rising from the plain. Deer and wild pig are plentiful in the wooded mountains in the west. There is abundant birdlife, including wild duck and pheasants.

Settlement patterns. Population distribution, as in the rest of China, is predominantly rural. The main concentrations of rural population are found in the lake plain around the Yangtze and lower Han, notably from Wu-han downriver to Huang-shih; the lower Han Basin below Chung-hsiang (former An-lu) to Wu-han; and between I-ch'ang and Sha-shih. There is a smaller concentration at Hsiang-fan at the confluence of the Han and Tang rivers. Here the villages are often strung along high, mud riverbanks, which give safety in time of flood. Villages are small, usually 10 families or less, and are usually about one mile or so apart. Urban population is concentrated in a few large towns and a large number of small ones. The conurbation of Wu-han is the second largest industrial and commercial centre in the Yangtze Basin. Other large towns are Huang-shih, Sha-shih, I-ch'ang, and Hsiang-fan. In the past, many of the larger towns were walled; many of these walls have been demolished and the stone used for building and road construction.

Population centres

The people. Hupeh's ethnic composition is homogeneous, being overwhelmingly Han (Chinese). Their dialect is closely akin to pure Mandarin. Most of the minority peoples are Hui (Chinese Muslims), widely scattered throughout north Hupeh and the Han plain. There are some T'u-chia and Miao people in the highlands of the southwest.

The economy. *Agriculture.* Hupeh is located in the agricultural transition zone between the wheat-growing North and the rice-growing South; it is one of China's leading rice-producing provinces. In south and southeast Hupeh, where rainfall is greater and irrigation more easily practiced, most of the cultivated land is devoted to rice growing. In northern parts, where rainfall is less and variability greater, rice occupies less of the cultivated area and wheat much more. Most of the paddy area is planted with a single crop—middle-season rice (rice planted in the middle of the season after winter wheat or barley has been harvested)—newer strains of which have a growing period of only 90 days. Winter crops grown on paddy fields are usually wheat, barley, and broad beans. Irrigation in the hilly lands is predominantly by means of gravity from ponds dammed higher up in the valleys. On the plains, where water has to be raised, wooden paddle pumps operated by hand are still used, but electrical pumping stations are rapidly replacing human labour. Food production decreases rapidly westward, where cultivation is confined mainly to deep valleys in the highlands.

Steel-rolling mill at the Wu-han Iron and Steel Corporation in Hupeh Province.

Cash crops

Hupeh ranks high among the Chinese provinces as a producer of cash crops, of which cotton is the most important. The main growing area lies north of the Yangtze in a belt stretching from Sha-shih eastward along the lower Han to Wu-han. Other important economic crops are vegetable oils (sesame, peanut [groundnut], and rapeseed) and fibres (ramie and hemp). Ramie is the fibre from which grass cloth or China linen is made. Some tea is grown on the hills in the southeast. Tung oil, a valuable forest product used in paints and varnishes, comes mainly from the western regions and the upper reaches of the Han and Yüan rivers.

Industry. Hupeh's mineral wealth consists chiefly of iron, copper, and phosphorus ores; coal; and gypsum. Some of China's richest and best iron ore is found at Ta-yeh in southeastern Hupeh. The exploitation of this ore and of coking coal from P'ing-hsiang in Kiangsi was the basis for the founding of an ironworks at Han-yang at the end of the 19th century. Ore from Ta-yeh and other mines was also the basis for the establishment of the Wu-han Iron and Steel Corporation, one of China's largest integrated ironworks. Completed in 1961, these works cover about four square miles and contain the largest blast furnaces in China. The Hunan No. 2 Auto Plant in Wu-han is a major national supplier of jeeps and small trucks. Huang-shih has also developed as a large iron and steel centre. Copper is found at Yang-hsin in the east and also at Ta-yeh. Reserves are large compared to those of other provinces, and production has increased considerably. Bituminous coal is found in the west and anthracite (hard coal) in the south and east. There are large reserves of gypsum and salt in the northeast, and a number of foreign-built plants produce chemical fertilizers.

With the restoration of its traditional role as a national centre of trade and transportation, the tri-city area of Wu-han has come to play an important role in the province's economic development. Wu-han is the second largest industrial and commercial city in the Yangtze Basin. Of its three constituent cities, Han-k'ou is the commercial and industrial centre; Han-yang, formerly residential, is now largely industrialized; and Wu-ch'ang is the administrative, educational, and cultural hub of the province. In 1983 the conurbation was given economic power on a level with the provincial government.

Transportation. For more than 2,000 years waterways have been the main means of communication in Hupeh. Wu-han, known historically as "the thoroughfare of nine provinces," is the largest inland port in the country. The Yangtze and Han rivers, with their tributaries, are used by all manner of craft. Large ocean freighters reach Han-k'ou, and small steam launches penetrate much farther inland. Steam and oil-fired craft, however, carry only a small portion of the total waterborne freight: huge coaster junks from Chekiang and Fukien provinces sail to Sha-shih and I-ch'ang, and the small stern-oared *hua tzu*—each rowed from the stern by one man—ply the smaller streams. In addition to the rivers, the lake plain is a network of drainage channels that are used for communication by the local people.

Railways

Until 1958 Hupeh's railways consisted entirely of the Peking–Han-k'ou and Wu-ch'ang–Canton line, which ran from north to south across the province. Because of political unrest, corruption, and lack of funds, by 1949 the Peking–Han-k'ou line was in a parlous state; rapid repair work was carried out by the Communist government. In 1959 the completion of the bridge over the Yangtze between Han-yang and Wu-ch'ang—the first bridging of the river over a length of 3,400 miles—wrought a revolution in the system by greatly increasing the value and efficiency of the whole north–south line from Peking to Canton.

More than half of the pre-1949 road network was rendered unusable by the Sino-Japanese War and subsequent civil war. Since 1949, much reconstruction and repair work has been done, and new roads have been built. Wu-ch'ang has become an important centre for air traffic, second only to Peking. Air services, formerly entirely under central government control, have been supplemented by a regional carrier.

Administration and social conditions. *Government.* From 1950 to 1954 Hupeh was part of the Central South greater administrative region. In 1954 provincial (*sheng*) government was established directly under the central government. In 1958 local government was greatly modified by the formation of communes, which took over the duties of the rural districts and market towns (*hsiang* and *chen*) and were made responsible for the functioning of all local life at this level. During the early years of the Cultural Revolution (1966–69) Hupeh was governed by a Revolutionary Committee composed of party cadres, the army, and the revolutionary mass organizations. The Revolutionary Committee was replaced in 1980 by the People's Government, which is the administrative arm of the People's Congress. The commune system was abolished in the 1980s, and the township government pattern of the 1950s was reestablished. Hupeh has six prefectures (*ti-ch'ü*), eight prefecture-level municipalities (*shih*), and one autonomous prefecture (*tzu-chih-chou*). Below that level are counties (*hsien*) and county-level municipalities (*shih*).

Provincial subdivisions

Education. The educational pattern in Hupeh is similar to that in the rest of the country. From 1949 onward determined efforts have been made to overcome illiteracy. By 1970 it was estimated that nearly two-thirds of the people were literate, and this percentage has steadily grown. Wu-ch'ang, which was the early capital of the ancient province of Hukuang, has remained the educational and cultural heart of Hupeh. Under the Nationalist (Kuomintang) government (1928–49), a national university was built on one of the three large lakes outside the old walled city, and a Christian university was established inside the city itself. After 1949 both these institutions were incorporated into the new educational system, which now includes more than 50 institutions of higher learning.

Medical service

Health and welfare. Before 1949 there were large, efficient modern hospitals, run by Christian missions and secular bodies in both Han-k'ou and Wu-ch'ang; good though many were, they were inadequate to meet the needs of the rural people. Insofar as rural needs were met at all, they were served by medical missionaries and nurses, scattered sparsely throughout the province, as well as by Chinese doctors, herbalists, and acupuncturists. From the 1950s the city hospital services were greatly enlarged, offering a choice of Western or Chinese medicine; most attention has, however, been paid to public health and to preventive medicine. Debilitating diseases such as schistosomiasis (a parasitic disease) and malaria were attacked; drinking water and the proper disposal of sewage were supervised; standards of personal hygiene and of the cleanliness of streets and public places were raised. These measures, and the equitable distribution of food, have served to improve health and increase production.

Cultural life. In common with all other provinces, Hupeh has experienced considerable change in its cultural life since 1949. The great extension of education and the increase in literacy have had a far-reaching effect. In the cities, museums and libraries have been opened and are much patronized. Large stadia, sports halls, and swimming pools have also been built. The theatre still retains great popularity, particularly the regional operatic form known as Chu opera.

The rural areas, no less than the towns, have undergone great cultural change. Electricity has been extended to villages and hamlets. Every village of any size now has its own stores, its library, and its hall, in which meetings are convened, health clinics are held, and table tennis is played. Being probably better lighted than individual homesteads, the hall has become the place where villagers assemble to chat or listen to the radio. Storytelling—an agelong profession, which is still very popular—serves to preserve folklore. Country life is enlivened by occasional visits of professional players, entertainers, and acrobats.

HISTORY

When China was slowly evolving in the Honan–Shansi region during the Shang and Chou dynasties (18th to 3rd century BC), Hupeh formed part of the kingdom of Ch'u. It was subjugated by Shih huang-ti (reigned 221–210/209 BC), who created the first united empire of China; it was finally assimilated into the Chinese state under the Han

dynasty (206 BC–AD 220). Hupeh at that time was described by the ancient Chinese historian Ssu-ma Ch'ien as:

> a large territory, sparsely populated, where people eat rice and drink fish soup; where land is tilled with fire and hoed with water; where people collect fruits and shellfish for food; where people enjoy self-sufficiency without commerce. The place is fertile and suffers no famine and hunger. Hence the people are lazy and poor and do not bother to accumulate wealth.

From this time on, the facility of communications afforded by its river system has caused Hupeh to figure prominently in Chinese history.

Since the mid-19th century it has been the centre of many momentous events, sometimes to its sorrow. The Taiping Rebellion, led by a Hakka, Hung Hsiu-ch'üan, broke out in Kwangsi in 1850, after which the rebel armies moved north, taking Wu-ch'ang in 1853. During the succeeding 10 years the central plains of Hupeh and Hunan were devastated by fighting and banditry. After China's defeat in the second Opium, or Arrow, War of 1856–60, the Hupeh cities of Han-k'ou, I-ch'ang, and Sha-shih were opened to Western nations as commercial ports. From this time on, European influence in central China steadily increased. Han-k'ou became the head of international oceangoing traffic. In the first 20 years (*i.e.*, until 1880) trade was based almost exclusively on tea, but, with increasing Indian and Ceylonese competition, Han-k'ou became the centre for the collection and processing of other central Chinese raw materials, notably vegetable oils, egg products, and tobacco.

Early role as a trade and industrial centre

Hupeh's industrialization began with the establishment of the Han-yeh-p'ing ironworks in Han-yang by Chang Chih-tung, the governor of the province, who also established a cotton mill in Wu-ch'ang opposite Han-k'ou. The ironworks had a checkered career. At first it enjoyed some government protection and tax exemption but later suffered from internal political unrest and instability, lack of capital, and poor management. Subsequently a Japanese concern gained financial control with a view to securing ore from Hupeh for its ironworks in Japan. The Han-yang works were allowed, even induced, to fall into decay. They were destroyed by bombing during the Sino-Japanese War of 1937–45 and were restored only after the advent of the Communist government in 1949.

The Chinese Revolution of 1911–12 began in Hupeh. The army in Han-k'ou mutinied, and the soldiers, led by their commander, Li Yüan-hung, took the cities of Han-k'ou, Han-yang, and Wu-ch'ang. Yüan Shih-k'ai led his northern troops, on behalf of the Emperor, against them and retook Han-k'ou but was unable to cross the Yangtze and eventually retired. This was the only significant fighting during the revolution. The province was ruled by a warlord (*tu-chün*) from 1916 to 1927, but from 1928 to 1938 there was some attempt at local government of a democratic Western pattern. When Nanking was taken by the Japanese in 1937, Han-k'ou became a temporary headquarters for the Nationalists; after the Nationalist retreat to Chungking in 1938, much of Hupeh came under Japanese control. A period of near chaos after the Japanese defeat in 1945 ended with the establishment of the People's Republic in 1949. (T.R.T./V.C.F./Ed.)

Kiangsu

A province on the east coast of China, Kiangsu (Chiang-su in Wade–Giles romanization, Jiangsu in Pinyin) is bounded by the Yellow Sea and by the provinces of Chekiang to the south, Anhwei to the west, and Shantung to the north. It occupies an area of 39,600 square miles (102,600 square kilometres). The provincial capital is Nanking, which was the southern capital of China during the Ming dynasty (1368–1644) and the capital under the National Government (1928–49). Kiangsu became a separate province in 1667 (the sixth year of the reign of the K'ang-hsi emperor). The name is derived from the prefixes of Chiang-ning and Su-chou, the names of the two most important prefectures within the province at that time.

The province consists almost entirely of alluvial plains divided by the estuary of the Yangtze River into two sections, Chiang-nan (literally, "South of the River") and Su-pei (northern Kiangsu). Chiang-nan is fertile and well watered, famed for its silk and handicrafts, and very densely populated and industrialized. The cities of Su-chou, Nanking, Wu-hsi, and Shanghai are all located in this region. Shanghai is situated at the mouth of the Yangtze River, although administratively the Shanghai Municipality is not a part of Kiangsu Province but is controlled directly by the State Council of the central government. Su-pei is relatively poor in comparison with Chiang-nan. The northernmost section of Su-pei, from Suchow to the sea, is actually part of the great North China Plain in its physical geography, as well as in its agriculture and general way of living; it is the poorest section of Kiangsu and is densely populated.

The land. *Relief.* The most important physical characteristic of the province is its wide alluvial plain, stretching from north to south, at a low elevation above sea level. Most of the soils are thus alluvial, both calcareous and noncalcareous, and including some saline soils. There is an intricate network of rivers and canals, lakes and ponds, all protected from floods by dikes. Most of the province is less than 150 feet (45 metres) above sea level. Hills of moderate elevation are found only in the southwestern corner of the province and in the extreme north along the Shantung border. Mount Yün-t'ai, in northern Su-pei near the Yellow Sea, is the highest point in the province, at 2,050 feet (625 metres). Nearly 10 percent of the total area is occupied by shallow lakes and reedy marshes. The silt of the great rivers encroaches constantly on the sea, leaving seaports of former ages dry. In coastal areas below the high-water level, cultivation is carried on in polders (areas protected from the sea, mainly by dikes). Extensive canalization and a vast development of polders have been systematically carried out during the 20th century. This section of the surface of the Earth has been completely altered by human hands.

Drainage. Chiang-nan is drained primarily by the Yangtze River, which enters the province to the southwest of Nanking on the Kiangsu–Anhwei border and flows generally east and southeast before reaching the East China Sea. The waters from upstream meet tidewaters at Nanking. The river becomes broader at Chen-chiang, widening to more than 11 miles at Nan-t'ung and more than 56 miles at its mouth. It carries an enormous load of silt to the sea annually, depositing it to form the Yangtze Delta. Tides and currents carry some of the sediment to form sandbars in the estuary and along the coast. The delta itself grows at an average rate of about 82 feet a year.

Su-pei's major drainage systems are Hung-tse Lake and the Huai River, which flows into the lake; Kao-yu Lake, through which waters from Hung-tse Lake reach the Yangtze; the Su-pei Canal, which drains Hung-tse Lake; and the Grand Canal, which runs through the entire province from north to south and connects Su-pei with the Yangtze Delta. During several periods in Chinese history, northern Kiangsu was also drained by the Huang Ho (Yellow River), which occasionally left its course and flowed into the Huai. Formerly, the Huai flowed into the sea, but when its channel was gradually usurped by the Huang, beginning more than a thousand years ago, it was unable to reach the sea and instead emptied itself into Hung-tse Lake.

The Kiangsu lowlands are floodplains formed by the alluvial deposits of the Yangtze, Huai, and Huang rivers and their tributaries. Using the Yangtze and the old channel of the Huai as convenient landmarks, the area of these plains may be divided into three sections.

The three sections of the plains

The Chiang-nan plain south of the Yangtze forms the principal part of the Yangtze Delta, characterized by flatness and lying only 10 to 16 feet above sea level. It is crisscrossed by streams and canals and dotted with ponds and lakes, forming an elaborate network of flowing water, meticulously maintained by farmers. This area actually has the highest stream density in China: within it, no place is more than 300 feet from the drainage system of T'ai Lake (the southern shore of which forms much of the Kiangsu–Chekiang border). The canals were all dug by farmers of the area. Isolated hillocks dot the edge of the T'ai Lake area, which adds to its enchanting beauty.

The lakes were parts of former shallow bays and inlets of the sea, obstructed and enclosed by the steady advance of the Yangtze Delta. After being cut off from the sea, the water gradually decreased in salinity and formed freshwater lakes. T'ai Lake is connected with the Yangtze and its estuary by many distributaries. The Chiang-nan Canal (the name for the section of the Grand Canal south of the Yangtze), which runs through the full length of the T'ai Lake plain from northwest to southeast, cuts across all the distributaries connecting the T'ai Lake basin with the Yangtze, thus forming a vital link of the T'ai Lake system.

Between the Yangtze and the ancient channel of the Huai is what Chinese geographers call the Yangtze–Huai plain, built by the alluvium of the two rivers. The centre of this plain is only 6½ to 13 feet above sea level, while its periphery stands at about 17 to 33 feet. It is considered to be a section of the Yangtze Delta, as it has the same topographical elements, including alluvial deposits and drainage. As a sluggish tributary of the Yangtze, the Huai formerly caused widespread floods during the high-water season, but a water-control project has permanently restricted the high waters of the Huai.

North of the old channel of the Huai is the Suchow–Huai plain, built of the alluvium of the Huai and Huang rivers and standing about 30 to 150 feet above sea level. In the northern part of the plain are low hills with heights of about 650 feet.

Yangtze Valley and North China climates

Climate. Within the province, two subtypes of climate may be distinguished: the Yangtze Valley climate, in central and southern Kiangsu, and the North China climate, to the north of the old Huai River. The former is humid subtropical, while the latter is cool, temperate continental, with greater extremes of temperature. Nanking in the south has a mean temperature of 36° F (2.2° C) in January and 82.4° F (28° C) in July. For northern Kiangsu, the mean January temperature is below 32° F (0° C), but summer is as hot as in the south. Annual precipitation generally increases from north to south, ranging from 24 to 47 inches (600 to 1,200 millimetres), that of Nanking being 41 inches. Seasons are distinct in both north and south. Between spring and summer, the south receives prolonged rains of cyclonic origin, typical of the Yangtze Valley and extremely useful for rice growing. The coast is often visited by destructive typhoons between late summer and early autumn.

Plant and animal life. In Su-pei grow temperate broad-leaved deciduous trees, typical of the North China Plain, while in southern Kiangsu are found subtropical mixed broad-leaved deciduous and broad-leaved evergreen trees, typical of the Yangtze Valley. As the whole of the province has been cleared for cultivation since ancient times, no primary forest remains. In natural flora, it is a markedly depleted territory, because of the dense population and intensive cultivation. There is a warmth-loving and moisture-loving fauna characteristic of the monsoon climate of East Asia. The fauna has considerable economic significance, fish, ducks, crabs, and shrimps being important sources of food. Fish raising is highly developed—the numerous ponds, reservoirs, lakes, canals, and streams are stocked with hundreds of millions of fry that are shipped to other provinces and are also exported to other countries.

There are also numerous agricultural pests, such as rodents and insects, which harm cultivated plants and trees. Great strides have been made in the control of the more common pests, but the insects that damage trees have not yet been brought under complete control.

Settlement patterns. Although almost 90 percent of Kiangsu's population is rural, the province contains many of the largest cities of the Yangtze Delta. The population distribution patterns of Kiangsu Province and the municipality of Shanghai are inseparable geographically and economically. Population density is higher in the north of the province, a fact explained by its earlier development, which dates from ancient times, and its importance as a communication link between North China and the Lower Yangtze Valley. Even the hilly district in southwestern Kiangsu has very high population densities in comparison with Europe and the United States. Shanghai is the largest municipality in China and one of the 10 largest in the world; it is not administratively a part of Kiangsu, being controlled directly by Peking. Other large cities in the region are Nanking, which is the largest city of Kiangsu proper and is its administrative and cultural centre; Su-chow (Hsü-chou), in northern Kiangsu; Su-chou, east of T'ai Lake; and Wu-hsi, in Chiang-nan.

The villages are distributed very close to one another on the Yangtze Delta, generally less than one-third of a mile apart. They are located mostly on the banks of rivers and canals. Villages with several scores of households are the most common. Communication between villages is usually very easy, thanks to canals and barges, rural roads, and the ubiquitous bicycle, somewhat as in the Low Countries of Europe. The houses are usually well built of brick baked in local kilns. Dwelling conditions are fair to good by Chinese standards.

Dispersed rural settlement is the rule along the coast and the rivers of northern Kiangsu. Dwellings are found singly along the riverbanks and quite close to each other in groups of two, three, or four among the rice fields.

The people. The population of Kiangsu is entirely Han (Chinese), with the exception of a few Hui (Chinese Muslims). The inhabitants of Chiang-nan speak the Wu (Shanghai) dialect, while those of northern Kiangsu and the Nanking area speak the eastern Mandarin dialect.

The economy. *Agriculture.* Kiangsu is one of the richest provinces in China, with a significant agricultural sector. Output is enhanced by multiple cropping, powered irrigation, tractors, and chemical fertilizers. The T'ai Lake plain produces rice, wheat, cotton, fruit, silk, tea, and fish. Tea is grown in the southwestern uplands around I-hsing, which produces the famous I-hsing china tea sets. Cattle, pig, and poultry raising are an important source of food and income, especially since the number and size of private plots allowed to each household increased. Fishing and pisciculture are other sources of food.

Crops

Industry. Nanking is the most important heavy industrial centre of Kiangsu proper. Major industrial plants produce trucks and parts for motor vehicles, chemical fertilizers, and detergent raw materials. The Nanking industrial area also produces steel, petrochemicals, electronics, machine tools, cameras, textiles, cement, and sundry building materials. Wu-hsi, near Shanghai, is a rising industrial centre with good inland waterway connections to all parts of the province. Modern manufactures include machine tools, agricultural and transportation equipment, cotton textiles, silk reeling, and food processing. Good deposits of iron and coal have been found at I-hsing and are used in a local ironworks and steelworks.

Kiangsu has become a major exporter since the 1970s. Goods formerly shipped through Shanghai are now handled through the provincial ports of Nan-t'ung, Chang-chia-kang, and Lien-yün-kang. Two of these ports have been designated "open" cities and encouraged to foster foreign trade and investment: Nan-t'ung, with 16 miles of deepwater frontage on the Yangtze, has developed its own economic and technical investment zone; and Lien-yün-kang, as the eastern terminus of the Lung-hai Railway, is a key export outlet for the central and northwestern provinces along the rail line. Kiangsu was incorporated into a larger Shanghai special economic zone in 1984.

Transportation. Among the assets of the province is the dense water transport network. With more than 14,000 miles of inland waterways, Kiangsu carries more than 50 percent of its goods by water. In contrast, its railroads carry only about 20 percent of the province's freight shipments. The completion in 1968 of the Yangtze rail and highway bridge at Nanking made the city a key north–south and east–west communications hub. The Grand Canal, which is periodically redredged, continues to play an important role in north–south transport.

Administration and social conditions. Kiangsu is divided into 11 prefecture-level municipalities (*shih*). The province also contains municipal districts (*shih-hsia-ch'ü*) and municipal counties (*shih-hsia-hsien*). The provincial capital, Nanking, is the military regional headquarters for eastern China.

Kiangsu has a rich educational tradition, with some of China's top arts and science universities, and a scientific

The Moon Sighting Pavilion in the Humble Administrator's Garden in Su-chou, Kiangsu Province.
Peter Carmichael—Aspect Picture Library, London

and technical work force that forms the basis of one of the country's centres of technology and research. With a predominantly rural population, however, the province's illiteracy levels are slightly higher than the national average. The proportion of the provincial population with a primary level of education or higher is just at the national average. Since 1949 health care has expanded greatly.

Two categories of cities

Cultural life. The cities of the province fall into two categories based on the standpoint of historical development—the ancient cities and the modern cities. The former date from ancient or medieval times and include Nanking, Su-chou, Yang-chou, Chen-chiang, and Suchow. Several of them are well known in East Asian history, are rich in cultural heritage, and have a long tradition that has found artistic expression in Chinese traditional architecture, painting, sculpture, flower gardens, stone bridges, and world-renowned handicraft industries, such as silk embroidery and carving of various materials. These cities often possess historical monuments, famous temples, and local shrines and *p'ai-lou* (arches) honouring their illustrious citizens. Many cities have a rich folklore. Nanking, especially, abounds in national monuments and famous historical relics. The most renowned are the simple Ming tombs (of Ming emperors) and the magnificent Sun Yat-sen Mausoleum, at the foot of Tzu-chin Hill. The gastronomic specialty of this ancient capital is the renowned Nanking salted duck. The duck is raised in ponds and lakes nearby. Other products from the Nanking area include handwoven silk (*tzu-ching*), particularly cloud brocades, which use every conceivable shade of colour to portray the clouds of sky at sunset.

The modern cities that sprang up in the 19th century after the Opium Wars and the Treaty of Nanking (1842), which opened China to international trade, include Shanghai, Wu-hsi, Nan-t'ung, and Lien-yün-kiang. Most of them are seaports, river ports, or railway junctions.

HISTORY

The state of Wu

In antiquity, the Kiangsu region was within the jurisdiction of the ancient state of Wu. During the Chou dynasty (*c.* 1111–255 BC) much of the area was called Kou-wu and was considered outside Chinese borders. During the Ch'un-ch'iu (Spring and Autumn) and part of the Chan-kuo (Warring States) periods from the 8th to the 3rd century BC, it was brought into the Chinese empire as one of the "outer states." Known as the Wu region during the Han dynasty (206 BC–AD 220), it became the independent state of Wu during the succeeding San-kuo (Three Kingdoms) period, with its capital at Chien-yeh, the site of modern Nanking. The golden age of culture in the region was during the Six Dynasties (AD 220–589), when it received a major influx of immigrants from the north. After the fall of the T'ang dynasty in 907, Yang-chou in Kiangsu became the capital of the Nan (Southern) T'ang state, which lasted from 937 to 975/976.

Another period of major cultural and commercial development occurred during the Nan Sung dynasty (1127–1279). In the early Ming dynasty Nanking became capital for the entire empire, and even after 1420, when the Ming capital shifted to Peking, Nanking remained as subcapital for South China. During the Ming and Ch'ing, or Manchu, dynasties, Chiang-nan was a major rice surplus region, supplying 40 percent of tribute tax grain to the capital by means of the Grand Canal. Chiang-nan merchants were among the most influential in China during this period. In the mid-19th century there was significant foreign commercial intervention, based on treaty port privileges. The region was seriously affected during the Taiping Rebellion of the 1850s and '60s, and Nanking became the Taiping capital in 1853, remaining under Taiping control until 1864.

In the 20th century Kiangsu became an important power base for the Nationalist Party (Kuomintang) of Chiang Kai-shek, and Nanking was made capital of the Nationalist government in 1928. It remained the puppet government capital under the Japanese occupation, after the Nationalist government moved to Chungking. During World War II the region was the locus of Communist-led guerrilla forces of the New 4th Army, from whose ranks many of Kiangsu's post-1949 leaders came.

Shanghai

For coverage of Shanghai, see the *Macropædia* article SHANGHAI.

SOUTH CHINA

Chekiang

Chekiang (Che-chiang in Wade–Giles romanization, Zhejiang in Pinyin), the third smallest province of China, is also one of the most densely populated and affluent. Its area is 39,300 square miles (101,800 square kilometres). A coastal province, it is bounded by the East China Sea on the east and by the provinces of Fukien on the south, Kiangsi on the southwest, Anhwei on the west, and Kiangsu on the north. The provincial capital is Hang-chou.

Chekiang has for many centuries been one of the great cultural and literary centres of China. Its landscape is renowned for its scenic beauty. The name of the province derives from its principal river, the Che ("Crooked") River, formally known as the Ch'ien-t'ang River at the estuary of Hang-chou Bay, and known as Fu-ch'un River inland. Chekiang is among the leading Chinese provinces in farm productivity and leads in the tea and fishing industries.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The northwestern section of the province (Che-hsi) lies within the fertile Yangtze River Delta, with its labyrinth of rivers and canals; its coastal lowlands are protected by dikes. The southern edge of T'ai Lake forms part of its northern border with Kiangsu. The greater part of Chekiang Province lies to the south of Hang-chou Bay and is largely mountainous. It has a rocky and deeply indented coast, dotted with more than 18,000 islands, forming numerous natural harbours. This part is in fact a continuation of the mountain ranges of

The delta and the mountains

Fukien, which run roughly parallel to the coast. In eastern Chekiang, mountains occupy 93 percent of the land surface, while another 1 percent consists of low hills. Only 6 percent is level land, distributed along Hang-chou Bay and the Fu-ch'un and Ta river valleys in southern Chekiang. Most of the province's arable lands—consisting of alluvial plains of great fertility—are found in these three areas.

Drainage. The chief river of the province is the Fu-ch'un (Ch'ien-tang) River, the drainage basin of which constitutes 40 percent of the total area of the province. The river has, in fact, two headstreams, one coming down from the southwestern highlands and flowing through the broad Lan River valley and the other rising in Anhwei Province and passing through Chien-te in Chekiang and other cities. On the latter tributary is located the Hsin-an River Dam and hydroelectric power plant, which is one of the largest in East Asia. The Ch'ien-t'ang Estuary tidal bore takes the form of a high wall of water that rushes upstream with a thunderous roar. Best seen just after the full moon and at its highest in the autumn (late September–early October), the bore is a famed tourist attraction. Along the estuary are miles of sea dikes that have been built throughout the ages to protect the rich rice lands of the delta. The other rivers of some importance are the Yung, Ling, and Ou; the Ou and its four principal tributaries together form the second largest river system of the province. Although these mountain streams flow swiftly through rocky channels and gorges, they are navigable to skillful boatmen using sampans (small, roofed boats propelled by sculling) right up to the mountains.

Coastal islands

Hang-chou Bay is almost as broad at its entrance as the Yangtze Estuary but is obstructed by a cluster of some 400 islands known as the Chou-shan (Chusan) Archipelago. The largest island in the group, Chou-shan, is a major coastal fishing centre. On P'u-t'o Mountain, a renowned scenic island east of Chou-shan, is one of the sacred mountains of Buddhism that once attracted pilgrims from all over East Asia.

Climate. Chekiang has a humid subtropical climate, controlled chiefly by monsoonal airflows, modified by local influences. Considerable differences exist between the coast and the hinterland, between the lowlands and the highlands, and between the north and the south, particularly in winter. Thus, Hang-chou, in western Chekiang, has an average January temperature of 39° F (4° C), while that of Wen-chou, on the coast, is about 46° F (8° C). Summer is hot throughout the province; the average July temperature at Hang-chou is 82° F (28° C), while that at Wen-chou is 84° F (29° C). Annual rainfall throughout the province is more than 40 inches (1,000 millimetres). The hilly interior has more precipitation than the coast, which is frequently visited by devastating typhoons, particularly during late summer and early autumn.

Plant and animal life. The vegetation of the northern, or T'ai Lake, plain differs from that of the rest of the province. Formed from a lake, it is covered with rich alluvial soil and is an open land of rice fields and rural settlements, dotted with some shade and ornamental trees. The original or natural vegetation disappeared centuries ago when the land was cleared for cultivation.

Mountain vegetation

The vegetation of the hilly and mountainous parts of the province, south of the plain, consists primarily of mixed evergreen broad-leaved and coniferous forests that grow on gray-brown podzolic (infertile forest) soils at the higher elevations and on red and yellow lateritic (leached, iron-bearing) podzolic soils on the lower slopes. There is an abundance of such trees as the laurel, pine, cypress, and beech. Besides the ubiquitous bamboo, the tung tree, which supplies valuable oil, is widely distributed in the upper Fu-ch'un Valley.

The province has an animal life typical of the subtropical forest zone and characterized by great diversity; it includes monkeys, anteaters, the southern heron, water turtles, many frogs, and numerous southern birds. There are many invertebrates, among which subtropical insects predominate, although tropical insects characteristic of southern Asia are also found.

Settlement patterns. There is a marked contrast between the densely populated plains and the sparsely populated uplands. Thus, two-fifths of the population in the province is concentrated in the T'ai Lake plain and in the coastal region of Hang-chou Bay. About 25 percent of the population lives in cities and towns. The capital and largest city is Hang-chou, located in western Chekiang; it is followed in size by the port cities of Ning-po and Wen-chou, both in eastern Chekiang. Other important cities are Shao-hsing and Chin-hua, in eastern Chekiang, and Chia-hsing and Wu-hsing (locally known as Hu-chou), in western Chekiang. All of these urban centres have a long history; the oldest, Shao-hsing, dates to the 6th century BC. Hang-chou was the capital of the Chinese empire during the 12th and 13th centuries. It was, however, only after the first Opium War (1839–42) and the opening of Ning-po to foreign trade that the modernization of the cities—particularly Hang-chou, Ning-po, and Wen-chou—began. Scores of other towns are distributed throughout the province. They include the county (*hsien*) capitals, which are located mostly on the agricultural plains and valley bottoms. Most of them are also local commercial centres, and some are developing into larger and more modern towns.

The people. The ethnic composition of the population is overwhelmingly Han (Chinese). Those belonging to ethnic minorities consist chiefly of She tribesmen living in the mountainous area of southern Chekiang, in the Wen-chou and Chin-hua prefectures along the Fukien border. The She tribesmen, of whom a greater number live in Fukien Province, have their own language, although most of them also understand Chinese. They grow paddy rice in terraces on hillslopes; farm work is done by both men and women. There are also small numbers of Manchu and Hui (Chinese Muslims) scattered in the cities and towns. The former are mostly descendants of Manchu soldiers garrisoned in Chekiang before the overthrow of the Manchu dynasty in 1911/12. With the exception of the Muslims and some Christians, the religious affiliation of the entire population in the province may be characterized as a complex of Taoism, Confucianism, and Buddhism. This form of religion is generally tolerated by the People's Republic, though the monks are required to engage in productive work to earn a living.

Religious affiliations

The economy. *Agriculture.* Chekiang is one of the more prosperous of China's provinces, leading the country in farm productivity in the tea industry and second only to Szechwan in sericulture (the raising of silkworms to produce raw silk). Its agriculture is among China's most diversified, with less than half its farm output by value coming from food or cash crops.

Because of the province's hilly topography, only about

Emil Schulthess—Black Star

Picking Lung-ching (Dragon Well) green tea near Hang-chou in Chekiang Province.

one-fifth of its land surface is arable. Two-fifths of the cultivated land lies in northern Chekiang, in the Yangtze Delta and on the southern shore of Hang-chou Bay. About four-fifths of Chekiang's arable land is irrigated—one of the highest ratios in eastern or southern Asia—and about two-thirds of the arable land is used to grow staple food crops—rice, wheat, barley, corn (maize), and sweet potatoes. The rest of the farmland grows either green fertilizer crops or such industrial crops as cotton, jute, ramie (a shrub yielding a fibre used for textiles), rapeseed, sugarcane, and tobacco. Most farmers also raise pigs and poultry on their small private plots, and many also raise fish in village ponds, reservoirs, or lakes and rear silkworms during the slack farming season in spring. In the well-watered hilly areas, tea is grown. All these activities provide a second income for peasant households.

Rice is the chief staple food and is grown widely throughout Chekiang Province, although the well-watered northern plains constitute the most productive area of cultivation. Both single-cropping and double-cropping systems are followed in paddy (rice field) cultivation. Since 1949 double-cropping of rice has been vigorously promoted, and its share in the rice acreage has increased to one-half of the total.

Rice and tea cultivation

Chekiang has four principal tea districts. The Hang-chou district produces the famous Lung-ching (Dragon Well) green tea. The P'ing-shui district has the largest tea acreage and the highest production of processed tea. The other two districts are Chien-te, in the southwest, and Wen-chou, in the southeastern hilly region. World War II caused serious damage to the tea industry as tea gardens were abandoned and aging shrubs were not replaced. During the 1950s a systematic rehabilitation and development program was undertaken. Improved methods of tea cultivation and processing were introduced and new orchards established, and the province resumed its position as China's leading tea producer.

Sericulture is another of Chekiang's traditionally famous industries. The principal silkworm-rearing areas are on the T'ai Lake plain. Secondary districts are located in the northeast and the northwest. These areas, which have a long history of sericulture, yield a consistently high quality of silk from the cocoons. The industry, like the tea industry, suffered serious damage during World War II and the civil war that followed, but vigorous measures to restore production have raised output.

The Chekiang coast lies at the convergence of western Pacific warm and cold currents. Its rivers carry rich organic material into the shallow waters above the continental shelf. As a result, many kinds of fish come there to spawn. More than 100 varieties of fish are found there. Important commercial catches include drums (or croakers), cutlass fish, and cuttlefish. The rapid growth of fishing has required readjusting fishing quotas to protect the fishing banks from overexploitation. A flourishing aquaculture industry has been developed, producing kelp, the edible red algae Porphyra (used in making soups and condiments), shellfish, and other marine products.

Fishing and aquaculture

Industry. Most of Chekiang's wealth derives from light industry. This in part reflects the province's historic role as a commercial and handicraft centre and a significant textile producer since the 1890s.

The province has few exploitable minerals, although local low-grade coal deposits are mined and consumed in a number of locations. China's largest fluorspar mine is located in southwest Chekiang and has been worked since the early 1930s. Oil exploration has been undertaken in the East China Sea off Wen-chou. Industrial development has been stimulated by the growth of electric power generation based on Chekiang's fast-flowing rivers. The Hsin-an River hydroelectric plant is one of the largest in China.

Hang-chou has become a major industrial city since 1949 and produces a wide range of industrial and consumer goods, including machinery, textiles, agricultural implements, chemicals, radios, and televisions. Ning-po is also a major industrial centre, producing tractors, electronics, and petrochemicals. The province has become a major exporter with a number of specialized export centres for light industrial products and handicrafts. The designation of Ning-po and Wen-chou as two of China's "open" cities has stimulated the planning of foreign investment and technology transfer programs, and Chekiang has been included in the Shanghai special economic zone.

A flourishing handicraft industry is located mostly in rural villages. Nationally and internationally known products include the porcelain of Lung-ch'üan, the silk umbrellas and tapestry of Hang-chou, embroideries, laces, wood and stone carvings, inlay ware, and a host of other products of Chinese folk art.

Transportation. The rivers play an important role in the province's transport; about half of the total freight volume travels on these inland waterways. The remainder of the freight volume is moved mostly by road, though heavier goods are often moved by rail, especially for longer distances. Although there are numerous harbours along the Chekiang coast, coastal shipping accounts for only a small percentage of the total freight volume. The Shanghai–Hang-chou railway is the most important trunk line, connecting western Chekiang with east and North China. The Chekiang–Kiangsi line links Chekiang with South and central China. The Hang-chou–Ning-po railway connects the southern littoral of Hang-chou Bay with the Chekiang–Kiangsi and the Shanghai–Hang-chou lines. A modern highway network with its primary centre at Hang-chou connects the province with the cities of Shanghai and Nanking and with the provinces of Anhwei and Fukien.

Administration and social conditions. *Government.* Chekiang Province was governed as part of the East China greater administrative region from 1950 until it came under the direction of the central government in 1954. It is divided into four prefectures (*ti-ch'ü*) and six prefecture-level municipalities (*shih*). Below this are counties (*hsien*) and county-level municipal districts (*shih-hsia-ch'ü*).

From 1958 to the late 1970s the administrative unit below the county was the commune. All administrative units, from the province downward, were theoretically governed by assemblies elected through indirect elections but actually run by local party leaders. In 1980 the People's Government and People's Congress were created to take over functions from Cultural Revolution-era governments.

Education. Chekiang has a strong tradition of locally supported education. Its levels of adult literacy and primary-level educated citizens are above the national average. The province boasts more than 20 institutions of higher learning.

Cultural life. During the Nan (Southern) Sung dynasty (1127–1279) the political and cultural centre of China moved from the North to western Chekiang. The Hang-chou area became the homeland of a galaxy of famous painters (including a Sung emperor), as well as of calligraphers, poets, essayists, philosophers, and historians. The beauty of Lin-an (modern Hang-chou), the Nan Sung capital, was immortalized by the landscape painters Hsia Kuei and Ma Yüan. The cosmopolitan legacy has lingered on in provincial pride and national stereotypes that often depict the Chekiang people as both cultured and affected. Various national and regional operatic traditions flourish, including the famous Yüeh opera of Shao-hsing. There are many distinct regional subcultures, with their own musical and culinary traditions.

Role as cultural centre

HISTORY

Before the 8th century BC western Chekiang was a part of the ancient state of Wu, while eastern Chekiang was the land of Yüeh tribes. In about the 6th century BC the two subregions became the rival kingdoms of Wu and Yüeh. The heartland of the Wu state lay in southern Kiangsu Province, whereas that of Yüeh occupied the coastal area to the south of the Ch'ien-t'ang Estuary where it merges into Hang-chou Bay. Yüeh and Wu engaged in constant warfare from 510 until 473 BC, when the Yüeh conquered Wu, after which the victorious kingdom became a dominant power in the Chinese feudal empire, nominally headed by the Tung (Eastern) Chou dynasty. Yüeh was itself subsequently subjected, first by the kingdom of Ch'u in 334 BC and then by the kingdom of Ch'in in 223 BC.

Yüeh (consisting of Chekiang and Fukien) was quasi-independent during the Han dynasty (206 BC–AD 220).

Chekiang later formed a part of the kingdom of Wu (220–280). During the T'ang (618–907) and Sung (960–1279) dynasties, Chekiang was divided into Che-hsi (Western Chekiang) and Che-t'ung (Eastern Chekiang), which became the traditional geographic divisions of the province.

Lin-an

Lin-an was made capital of the Chinese empire during the Nan Sung dynasty, and its population in 1275 was estimated at about 1,000,000. Marco Polo, who visited the city, described it as the finest and noblest in the world. Odoric of Pordenone also visited the city, which he called Camsay, then renowned as the greatest city of the world, of whose splendours he, like Marco Polo and the Arab traveler Ibn Baṭṭūṭah, gave notable details. Chinese, Mongols, Nestorian Christians, and Buddhists from different countries lived together peaceably in the city during this period. Hang-chou continued to be a great cultural centre until 1862, when it was destroyed during the Taiping Rebellion. Of its citizens, 600,000 were slaughtered, while the rest either drowned themselves or else perished from starvation and disease. Hang-chou did not fully recover from this disaster, but it was eventually rebuilt and underwent gradual modernization.

Foreign penetration of Chekiang began in the 1840s with the opening of Ning-po as a treaty port city. Ning-po merchants gradually established commercial networks in Shanghai and along the coast. In 1913 a railroad linking Hang-chou to Shanghai was built. During the Chinese Revolution of 1911–12 the moderate landed elite seized power, but the province soon fell into the hands of warlords and became in the mid-1920s the power base of Sun Ch'uan-fang. In the late 1920s the province became a base of power for the Nationalist Party (Kuomintang) of Chiang Kai-shek, who was born at Feng-hua near Ning-po. The Chekiang elite came to dominate the Nationalist regime, and the province benefited from modernization programs introduced between 1928 and 1937. The Japanese occupied much of Chekiang after 1938, but the harbour at Wen-chou remained in Chinese hands from 1938 to 1942.

(F.Hu./V.C.F.)

Chuang Autonomous Region of Kwangsi

The Chuang Autonomous Region of Kwangsi (Kuang-hsi in Wade–Giles romanization, Guangxi in Pinyin) is bounded by the Chinese provinces of Yunnan on the west, Kweichow on the north, Hunan on the northeast, and Kwangtung on the southeast, and by Vietnam and the Gulf of Tonkin on the southwest. It covers an area of 85,100 square miles (220,400 square kilometres). Nanning, the capital, is about 75 miles (121 kilometres) southwest of the region's geographic centre. The name Kwangsi dates to the Sung dynasty (960–1279), when the region was known as Kuang-nan Hsi-lu, or "Wide South, Western Route" (western half of all territory south of the Nan Mountains). The Yüan dynasty (1206–1368) contracted the name to Kwangsi when it created a province out of the western half. In 1958 the province was transformed into the Chuang Autonomous Region of Kwangsi—a step designed to help foster the cultural autonomy of the Chuang, or Chuang-chia, people, who constitute the largest minority living in the region.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Kwangsi forms a tableland that descends in elevation from the north and northwest to the south and southeast. Elevations between 3,000 and 6,000 feet (900 and 1,800 metres) above sea level are reached at the edge of the Yunnan–Kweichow plateau in the northwest, the Chiu-wan and Feng-huang mountains in the north, and the Yüeh-ch'eng Mountains in the northeast. The greater part of the region is composed of hilly country lying at a height of between 1,500 to 3,000 feet. In the west, the Tu-yang Mountains rise to 6,500 feet. In the southeast, lowlands are situated at a height of between 300 and 1,500 feet.

The predominance of limestone gives many parts of Kwangsi a spectacular type of landscape known as karst, in which pinnacles and spires, caves and caverns, sinkholes, and subterranean streams abound. Picturesque rocky hills,

The karst landscape along the Li River, a tributary of the Kuei River, near Kuei-lin, Chuang Autonomous Region of Kwangsi.

spires of grotesque proportions, and strangely shaped caves with all types of stalactites and stalagmites are found in many parts of this region.

Drainage and soils. The Ch'in and Nan-liu rivers flow into the Gulf of Tonkin. The headwaters of the Hsiang River flow into Hunan Province. The remainder of the region's numerous rivers—including the Hung-shui, Liu, Ch'ien, Yu, Tso, Yü, Hsün, and Kuei—follow the general southeastward slant of the terrain. They rise from a profusion of sources and flow into one another in a succession of convergences until they merge into one major river, the Hsi. This mighty river rises in Yunnan Province and cuts across the entire width of Kwangsi before emptying into the South China Sea near Canton in Kwangtung Province.

The Hsi River Basin

The hilly areas are composed of red soil, while the lowlands are characterized by alluvial soil brought down by the many rivers.

Climate. Throughout the region, temperatures are warm enough to assure agricultural production throughout the year. The summer, which lasts from April to October, is marked by enervating heat and high humidity. Winters are mild and snow is rare. July temperatures vary between 80° and 90° F (27° and 32° C), while January temperatures range between 40° and 60° F (4° and 16° C).

Because of the influence of the rain-bearing monsoon wind, which blows from the south and southwest from late April to the end of September, precipitation is abundant. Drier areas are in the northwest, while the wetter areas are in the south and east. The average annual rainfall varies from 35 inches (890 millimetres) in the drier areas to 68 inches in the wetter zones. Most of the precipitation occurs in the period between May and August. In the extreme south, rain bursts caused by typhoons occur between November and February.

Plant and animal life. Stands of fir, red pine, cedar, camphor, and rosewood are found in the north and west; oranges grow in profusion in the south; while the cassia tree, anise, and betel palm flourish in many parts of the region. In central and south Kwangsi, many denuded hillsides have been taken over by tall coarse grasses, which are used for fuel or as pasturage for young water buffalo. Prominent types of wildlife include the bison, boar, bear, gibbon (a kind of ape), hedgehog, and cockatoo.

Settlement patterns. Almost 90 percent of Kwangsi's population lives in rural areas. The population density is unevenly distributed. Approximately two-thirds inhabit

the eastern third of the region, while only one-third occupies the remainder of the territory to the west. The principal cities of the region are the capital city of Nan-ning, the major city and industrial centre of the southwest; Liu-chou in the north, a hub of water and rail transport, the trading centre for the region's forest products, and a burgeoning industrial area; Kuei-lin in the northeast, which lies on the traditional trade route to central China and is a leading educational and commercial centre; Wu-chou in the southeast, the gateway to trade along the Hsi River; Pei-hai on the Gulf of Tonkin, one of China's designated "open" coastal cities; and P'ing-hsiang on the China–Vietnam border, which is a major centre of regional and international trade.

Chuang, Yao, Miao, and Tung peoples

The people. The population includes Han (Chinese), Chuang, Yao, Miao, and Tung. The Chuang are found largely in the western two-thirds of the region, while the Han are concentrated in the eastern third. Two distinct Chinese linguistic influences can be noted—Southwest Mandarin is spoken in the Kuei-lin district in the northeast as well as in the north, while Cantonese is spoken throughout the remainder of the region. The Yao, Miao, and Tung settlements are widely scattered.

The Chuang, a Tai people, have inhabited Kwangsi since classical antiquity. Living on the plains and in the river valleys of the hilly west, they cultivate paddy rice and practice an economy that easily merges with that of the Chinese. They are often referred to as "water dwellers" because their settlements are close to water and their dwellings are constructed on piles or stilts. For two millennia the Chuang have coexisted with the Han. The Chuang have absorbed Chinese culture, speaking both their own dialects and Cantonese. A romanized Chuang alphabet has been created and is one of the four writing systems to be printed on Chinese bank notes.

The origins of the Tung are not clear, but they are generally considered to be a branch of the Chuang, whom they resemble closely. They live in the high mountains close to the Kweichow border to the north. The Miao and the Yao, however, have long resisted the absorption of Chinese culture. They belong to a separate linguistic branch of the vast Sino–Tibetan language family. Neither the Miao nor the Yao dialects were written until alphabets based on adaptations of the Latin script were introduced in the late 1960s.

Upland dwellers who suffer from a scarcity of arable land, the Miao and the Yao practice subsistence agriculture. Characteristically, the Miao–Yao settlements are removed from transportation routes and are walled for defense. Besides farming and lumbering, which form the basis of their economy, the Yao make charcoal and bamboo basketry.

The economy. Since 1949 the region has made considerable progress in its economic development. Dams, canals, and reservoirs have been built to help irrigate dry lands; hydroelectric stations have been constructed and mineral resources exploited to stimulate modern industry; and rural industries have been developed in an effort to diversify village economy. Kwangsi has become self-sufficient in rice and, in fact, exports surplus rice to Kwangtung.

Resources. The region has sufficient coal and iron deposits to support moderate industrial development. Coal is mined north of Kuei-lin and south of Liu-chou. Iron is mined in the area near the Kwangtung–Hunan border as well as in southeastern Kwangsi. Other exploited mineral resources include tin (of which Kwangsi is a major producer), tungsten, manganese, and antimony. Moderate amounts of bismuth, zinc, and lead are also produced.

Agriculture. Only small areas of the region are under cultivation. Agriculture is concentrated in the river valleys and on the limestone plains. The hillsides are terraced wherever feasible. Since the 1950s the government has been seeking to bring new land under cultivation and to increase the yield of areas already cultivated by the use of irrigation and tractors. Major food crops include rice, corn (maize), wheat, and sweet potatoes. The leading commercial crop is sugarcane; other important commercial crops include peanuts (groundnuts), sesame, ramie (China grass), tobacco, tea, cotton, and indigo. Kwangsi is also a rich producer of a wide variety of fruits. The raising of livestock in Kwangsi is ancillary to farming. Water buffalo are used as draft animals in the paddy fields. Pigs, chickens, and ducks are raised on farms, and goats are raised in the hills. In many areas silkworms are also raised.

Fishing. Fishing is extensive. Both inshore and deep-sea fishing are carried on in the Gulf of Tonkin, which contains some of the world's richest fishing grounds. Catches include croaker (a fish that makes a croaking noise), herring, squid, prawns, eels, perch, mackerel, sharks, and sturgeon. The catching of fish fry in the region's many streams is characteristic of the freshwater fishing industry. Fish culture and the production of silkworms are complementary; the waste cocoons of silkworms are fed to the fish, and mud from fishponds is used as fertilizer for the mulberry bushes on which the silkworms feed.

Use of forest products in traditional Chinese medicines

Forestry. Kwangsi is an important producer of timber and forest products. In the north, large quantities of pine, fir, cedar, and giant bamboo are exploited. Red and black sandalwood are also produced in the west. More important, however, are sandarac (a resin used in making varnish and incense), star anise (Chinese anise), cassia bark (Chinese cinnamon), nutgall (a swelling on oak trees that produces tannin), and camphor. Tung oil, tea oil, and fennel oil are also produced. Some of these and other products are vital to traditional Chinese medicine.

Industry. Light industries produce textiles, paper, flour, silk, leather, matches, chemicals, and pharmaceuticals as well as sandarac gum, sugar, dyestuffs, and oils and fats. Pine resin is a particularly notable export of Wu-chou. Heavy industries include the ironworks and steelworks at Liu-chou and Lu-chai, machinery production at Nan-ning and Wu-chou, and the cement works at Liu-chou. The numerous handicraft products made in the region include cotton and ramie cloths, bamboo paper and rice paper, and bamboo combs. About one-tenth of the region's light industrial enterprises were granted autonomy in management in the late 1970s, and this restructured group accounted for nearly half of production and more than four-fifths of all industrial projects by the early 1980s. Tourism, especially oriented toward the city of Kuei-lin, has increased sharply and has become a significant source of income for the region.

Transportation. The elaborate system of waterways provides transportation throughout almost all of the region. A large proportion of the traffic is by junk, although portions of many rivers are navigable by motor launches and occasionally even by small steamers. The Hunan–Kwangsi railroad runs diagonally across the region from the northeast to the southwest. It forms a vital continental artery that connects with the Canton–Han-k'ou railroad and, south of P'ing-hsiang, with the Vietnamese railroad. The Kwangsi–Kweichow railroad links Liu-chou with Kuei-yang, Kweichow Province, and, along with the Liu-chou–Chih-chiang line, opened in 1983, is an impetus to the development of northern Kwangsi. The highway system has been substantially extended and improved since 1949. The highway network forms a central rectangle—with Nan-tan (in the northwest), Liu-chou, Nan-ning, and Pai-se (in the west) at its four corners—from which other roads radiate. Running almost due north and south, a trunk road connects Tu-yün in Kweichow Province, Nan-tan, and Nan-ning with the coast of the Gulf of Tonkin.

Administration and social conditions. *Government.* The region's administration is organized in a series of hierarchical levels. The top is the autonomous regional level, directly under the central government in Peking. At the second level there are five prefecture-level municipalities (*shih*) and eight prefectures (*ti-ch'ü*). Below these are county-level municipalities (*shih*), counties (*hsien*), and autonomous counties (*tzu-chih-hsien*). The lowest administrative units are the townships.

National minorities' education

Education. A special educational feature in Kwangsi is the program for the education of national minorities. Minority languages are used for instruction in primary and middle schools, written scripts, such as that for Chuang, are developed for spoken minority languages wherever needed, minority teachers are trained, and government subsidies are provided for minority students. Instruction in the Chuang language is offered where the size of the

Chuang population warrants it. The Institute for Minorities in Nan-ning trains both intellectuals and technical specialists of minority descent to work among the minority peoples below the county level. Institutions of higher education include the Kwangsi Normal College at Kuei-lin, as well as the Kwangsi Agricultural Institute and the Kwangsi Medical College, both at Nan-ning. The Kwangsi Provincial Museum and the Provincial Library of Kwangsi are located in Kuei-lin.

Health and welfare. Since the 1950s Kwangsi has made significant progress in public health and medicine. Such widespread diseases as malaria, smallpox, measles, and schistosomiasis (a parasitic infestation of the bladder or intestines) have been brought under control. The addition of iodine to water has ended the once-frequent occurrences of goitre, and the liver-fluke disease has been overcome by filling in old canals that were sources of infection and digging new ones. There is also a mass program to combat leprosy. Traditional Chinese medicine has been promoted to compensate for the shortage of Western medicine.

A basic social welfare system is available. Welfare funds guarantee care for the sick, disabled, and aged and provide relief in times of drought or flood. For industrial workers, there are accident prevention and insurance programs that provide for hospital treatment, sick leave, disability compensation, maternity leave, old-age benefits, and death benefits. Supplementary benefits are offered to those who participate in government programs such as birth control. The government has improved housing, expanded recreational facilities, and provided public-health centres.

Cultural life. The primacy of Chinese culture is widely recognized. Because the minorities in Kwangsi possess neither a unified organization nor support by fraternal groups, their assimilation by the Chinese is far more advanced than in the other autonomous regions. The underlying causes of what appear to be the region's ethnic tensions are economic and geographic factors that have exerted a powerful influence on cultural trends.

HISTORY

Early history. Kwangsi was known as the land of Pai-Yüeh (the Hundred Yüeh—referring to the aborigines of South China) during the Chan-kuo (Warring States period) of the Tung (Eastern) Chou dynasty (475–221 BC). A subgroup of the Tai people, known as the Chuang, inhabited the region and had an economy based on wet (irrigated) rice. Eastern Kwangsi was conquered by the Han people in 214 BC under the Ch'in dynasty, and the Ling Canal was dug to link the Hsiang and Kuei rivers to form a north–south waterway.

The invasion of the Han

An independent state known as Nan Yüeh (Southern Yüeh) was created by Gen. Chao T'o, with Chuang support, at the end of the Ch'in dynasty and existed until it was annexed in 112–111 BC by the Han dynasty (206 BC–AD 220). The Han rulers reduced the power of the Chuang people by consolidating their own control in the areas surrounding the cities of Kuei-lin, Wu-chou, and Yü-lin.

In AD 42 an uprising in Tonkin was quelled by an army under Gen. Ma Yüan, who not only sought victory on the battlefield but also showed concern for the well-being of the people. He reorganized Kwangsi's local government, improved public works, dug canals, and reclaimed land to increase production. Temples erected to his memory can still be seen in many places.

From the end of the Han to the beginning of the T'ang dynasty (618–907), the influx of Yao tribes from Kiangsi and Hunan added to racial tensions in Kwangsi. Unlike the Chuang, the Yao resisted Chinese culture. The hill country of Kuei-p'ing, Chin-hsiu, and Hsiu-jen in central eastern Kwangsi (the Ta-yao-shan region) where they settled became a centre of chronic unrest. In subsequent dynasties there were further migrations of the Yao from Hunan and Kweichow provinces.

Under the T'ang dynasty, Kwangsi became a part of the Ling-nan Tao (large province). The noted scholar Liu Tsung-yüan was prefectural administrator at Liu-chou. Irked by Chinese expansion, however, the Chuang people moved to support the Tai kingdom of Nanchao in Yunnan. Kwangsi was then divided into an area of Chuang ascendancy west of a line from Kuei-lin to Nan-ning and an area of Chinese ascendancy east of the line. After the fall of the T'ang, an independent Chinese state of Nan (Southern) Han was created, but it was liquidated by the Sung dynasty in 971.

The Sung governed Kwangsi from 971 to 1279 by the alternate use of force and appeasement—a policy that neither satisfied the aspirations of the Chuang nor ended the savage warfare waged by the Yao against the Chinese. In 1052 a Chuang leader, Nung Chih-kao, led a revolt and set up an independent kingdom in the southwest. The revolt was crushed a year later, but the region continued to seethe with discontent. The Yüan dynasty imposed direct rule and made Kwangsi a province, but relations between the government and the people did not improve. To further complicate race relations, another aboriginal people—the Miao—migrated from Kweichow, and more Chuang also came from Kiangsi and Hunan.

Independent Chuang kingdom

Confronted with a complex situation, the Ming dynasty (1368–1644) actively promoted military colonization in an effort to undermine the tribal way of life. It governed the minority peoples through the hereditary *t'u-ssu* (tribal leaders serving as the agents of Chinese government). This led to some of the bloodiest battles in Kwangsi history—notably, the war with the Yao tribesmen at Giant Rattan Gorge, near Kuei-p'ing, in 1465.

The Ch'ing (Manchu) dynasty (1644–1911/12) placed the minorities under direct Imperial rule in 1726. This, however, did not bring peace. Following a Yao uprising in 1831, the great Taiping Rebellion broke out in 1850—again near Kuei-p'ing and under minority leadership—lasting for more than a decade.

Meantime, the execution of a French missionary in western Kwangsi led to an Anglo-French War against China that was concluded by the humiliating treaties of Tientsin in 1858. Then, following the Sino-French War of 1883 to 1885, French supremacy in Vietnam exposed Kwangsi to foreign encroachment. Lung-chou was opened to foreign trade in 1889, Wu-chou in 1897, and Nan-ning in 1907; while in 1898 France obtained a sphere of influence that included Kwangsi.

The revolution. Together with neighbouring Kwangtung, Kwangsi in the early years of the 20th century became the base of the nationalist revolution led by Sun Yat-sen. Between 1906 and 1916 the provincial leaders of Kwangsi supported the establishment of a republic, and during the following decade played an active role in the reorganization of the Chinese Nationalist Party (Kuomintang). Following the rise of Chiang Kai-shek to power in 1927, the Kwangsi leaders (notably Li Tsung-jen and Li Chi-shen) formed the Kwangsi Clique in opposition to Chiang. The group did much to modernize Kwangsi but maintained a defiant posture against the central government. Although Chiang crushed their revolt in 1929, he was unable to end the semi-independent status of the region. The Chuang, on their part, formed a string of revolutionary soviets (elected Communist organizational units) between 1927 and 1931 that gave rise to new Communist leaders.

During World War II Kwangsi was a major target of Japanese attack. The Japanese invaded southern Kwangsi in 1939 and occupied Nan-ning and Lung-chou. In this period Kuei-lin became the principal base for the Chinese and Allied air forces, as well as the home of the patriotic press, the *National Salvation Daily News.* In 1944 the Japanese made a determined drive into Kwangsi; although they briefly took Kuei-lin, Liu-chou, and Wu-chou, they were unable to maintain their position. Chinese forces subsequently recaptured the major cities. In the civil war that followed World War II, the Chinese Communist forces took Kuei-lin in November 1949, and Kwangsi became a province of the People's Republic; the autonomous region was created in 1958 in an effort to satisfy local aspirations.

World War II

(P.-c.K./V.C.F.)

Fukien

Fukien (Fu-chien in Wade–Giles romanization, Fujian in Pinyin) is a province on the southeastern coast of China to

the northwest of the island of Taiwan. It is bordered by the provinces of Chekiang to the north, Kiangsi to the west, and Kwangtung to the southwest; and by the East China Sea to the northeast, the Taiwan Strait to the east, and the South China Sea to the southeast. It occupies a strategic maritime position linking the two sections of the China Sea. One of the smaller Chinese provinces, Fukien has an area of 47,500 square miles (123,100 square kilometres). Its capital and largest city is Fu-chou ("Happy City").

The name of the province, Fukien, means "Happy Establishment." The province is also known as Min Sheng (Min Province), after the "seven Min tribes" that inhabited the area during the Chou dynasty (1111–255 BC). It was, however, during the Sung dynasty (AD 960–1279) that the name Fukien was adopted and the basic geographical boundaries of the province were established. The region is one of the most picturesque in Asia, with wooded hills and winding streams, orchards, tea gardens, and terraced rice fields on the gentler slopes.

Small boats on the Min River near Fu-chou in Fukien Province.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* About 95 percent of Fukien is mountainous. The province is crossed by several ranges of moderate elevation that run roughly parallel to the coast. They constitute a part of a system of ancient blocks of mountains trending from southwest to northeast. The Fukien–Chekiang section forms a part of a raised massif that has been subjected to folding and refolding. A sharp natural boundary exists to the west and northwest between this uplifted block, on the one hand, and the low-lying Kiangsi Basin and the southwest part of Chekiang Province, on the other. Along this boundary run the Wu-i Mountains, which, in the extreme north, include the Hsien-hsia Mountains on the Chekiang–Fukien border.

The Wu-i Mountains, which form a formidable natural barrier between Fukien and the interior of China, reach a height of about 6,000 feet (1,800 metres) in western Fukien and in adjacent parts of southwest Chekiang. The range forms the watershed between the Min River system to the southeast and the Kan River system—a tributary to the Yangtze—to the northwest. The few passes across the Wu-i Mountains are high and difficult.

The mountain ranges tend to be more compressed in the interior and to broaden out toward the coast. Faults occur both along the axes of the mountains and across them, thus causing an extreme fragmentation of the land surface, so that local relief forms a complicated pattern.

Fukien has a submerged rocky coast that abounds in islands and islets, capes and peninsulas, and bays and havens. The shoreline is extremely irregular, with a total length estimated to be 1,680 miles (2,700 kilometres). The chief offshore islands are Quemoy (Chin-men, under Chinese Nationalist control), Hsia-men, and Tung-shan in the south; and Hai-t'an and Matsu (Ma-tsu, also under Nationalist control) in the north.

Drainage. Rivers are of great importance in Fukien, having for centuries provided the only means of transport. They flow into estuaries that form natural harbours, and their abundant water supplies are used for domestic consumption as well as for the irrigation of the myriad rice fields in the alluvial plains along their courses.

The general slope of the land descends from the northwest to the southeast. The main rivers cut across the intermediate ranges in deep gorges, while their tributaries drain broader intermontane valleys that follow the grain of the relief. The result is an almost perfect example of the trellis pattern of stream drainage, particularly well illustrated in the Min River system.

Min River system

The drainage area of the Min River of Fukien (to be distinguished from the Min River of Szechwan Province) occupies about half of the province. It is formed by the confluence upstream of three rivers, the largest of which is the Chien, which flows from its source near the Fukien–Chekiang border. The Chien has its own subsystem of tributary streams that drain the famous Wu-i tea district. The second source stream of the Min, the Fu-t'un, is also called the Shao-wu for the chief city of the region; it flows down the eastern slopes of the Wu-i Mountains. The third source, the Sha, flows from the south and southwest, arising on the eastern slopes of another section of the Wu-i range. The three streams, converging from the north, south, and west, meet at Nan-p'ing, their waters uniting to form the Min, which flows southeast past the city of Fu-chou to the sea.

To the south of the Min is the Chiu-lung River, which has its outlet to the sea at Amoy (Hsia-men). To the southwest of the Min is the Han River, which crosses the southwestern border of Fukien Province to empty into the sea at Swatow, the main port of eastern Kwangtung.

Soils. After centuries of rice cultivation, soils in the valley plains have been greatly modified. Well-developed gray-brown forest soils are widely distributed in the forest areas of the interior mountains, whereas mature red soils are common in the low hills and on high terraces. White saline soils and salt swamps are found in the coastal flatlands. Their parent rocks are marine saline deposits, penetrated by seawater. Attempts at desalination appear to have been successful, and some soils that were formerly saline are now used for rice cultivation.

Climate. Fukien lies just north of the Tropic of Cancer. The climate along the coastal area of the province is semitropical—very hot in summer but cool in winter. The mean temperatures in Fu-chou are about 84° F (29° C) in July and about 52° F (11° C) in January. There are three seasons in the year. November through February is the cool season; March through May, the warm season; and June through October, the hot season. The growing period lasts throughout the year. The northwestern mountains have a temperate climate but can become very cold in winter.

Summer is dominated by a monsoonal (rain-bearing) tropical airflow from the sea. Rainfall increases from the coast to the western mountains and averages between 50 and 80 inches (1,270 and 2,030 millimetres) a year. Some precipitation occurs in winter, occasionally in the form of snow in the northwest. The coast is subject to typhoons during late summer and early autumn.

Plant and animal life. The province has extremely varied vegetation, ranging from tropical species to forest and plant types associated with a cold temperate climate. Commercial forests are located upstream in the mountainous and rainier interior, away from rural settlements. The province has subtropical, laurel-leafed forests, as well as many kinds of conifers. In western Fukien the lower elevations support tropical mountain forests. The lianas are purely tropical. Tree ferns grow in the ravines. Higher up, where altitude modifies the climate, deciduous trees, conifers, and rhododendrons occur. Animal life in Fukien

is of the subtropical forest variety and is characterized by great diversity, with many kinds of birds, amphibians, and reptiles.

Settlement patterns. About one-fifth of Fukien's population lives in cities and towns, the rest in rural areas. Population densities are lowest in the mountain uplands, increase in the river valleys, and are highest on the coastal plains and estuaries near Amoy, Ch'üan-chou, and Fu-chou.

Minority groups

The people. Han (Chinese) make up nearly all of the population. The largest ethnic minority group consists of She tribesmen (She Min). Those who live in Fukien are located in the hilly hinterland of the northern coast. Most of them are distributed in the four counties of Fu-an, Hsia-p'u, Fu-ting, and Ning-te; all are engaged in farming.

Other minority groups include the Miao, Hui (Chinese Muslims), and Manchu. The Miao are distributed in the mountainous interior of northern Fukien; the Hui live in the cities of Fu-chou, Amoy, and Ch'üan-chou; and the Manchu live principally in Fu-chou, being descendants of Manchu soldiers who garrisoned Chinese cities during the Ch'ing (Manchu) dynasty. The She people, culturally affiliated with the Miao and the Yao, are not officially recognized as an ethnic group. They are distributed in the northern mountains, from the coast to the interior, and are even found beyond the Fukien border in Kiangsi and southern Chekiang. Nor are the "boat people" (Tanka or Tang-chia), who live on boats in the streams and estuaries, recognized as a separate group.

The four principal dialects

There are four principal local dialects in Fukien. Hokchiu (the Fu-chou dialect) is spoken principally in Fu-chou and in the Min-hou area corresponding roughly to the area of the former Fu-chou Fu (prefecture). Hokkien, the Amoy dialect, is spoken in southern Fukien (thus, it is also known as the Min-nan, or south Fukien, dialect). The Hokchia, or Hakka, dialect of Fukien is spoken in the upper Han Valley of southwestern Fukien. Lastly, the Henghua dialect is spoken in the Henghua district between Fu-chou and Amoy. There are also literally hundreds of subdialects, making the province one of the most linguistically fragmented in China.

The economy. *Agriculture.* Since the 1950s Fukien has largely been a net importer of food grains despite significant growth in output. Its major crops are sugarcane, peanuts (groundnuts), citrus fruit, rice, and tea. Fukien's sugarcane yields are among the highest in the nation. Much of the province's productivity comes from its use of chemical fertilizer. A growing proportion of agricultural output has also come from noncrop sources, particularly from fisheries, animal husbandry, and forest products. The most important woods are fir, pine, and rosewood, mostly floated in the form of big rafts down to Fu-chou, a great timber emporium. Plans emphasize the more intense exploitation of Fukien's hilly uplands as the key to its more rapid agricultural diversification.

Two crops of rice are harvested each year, the first in June, the second in September. The export of tea from Fu-chou to the European market has become insignificant, but Fukien remains a great tea-growing province with a large domestic market. A special feature is its production of flower-scented teas, for the manufacture of which there are factories in Fu-chou. There are also factories for the manufacture of paper from bamboo pulp.

Fukien also has considerable mineral wealth, including coal, iron, copper, gold, graphite, and kaolin (china clay) for making porcelain. Mines are widely scattered over the province.

Industry. Before 1949 Fukien had little modern industry. The modern Fu-chou Shipyard was built in 1866, but it was largely destroyed in the 1880s. There was some Russian and Japanese investment in tea and textiles in the 1870s and a spurt of overseas Chinese investment in food-processing industries in the coastal areas in the early 1900s, but overall, the modern industrial base was negligible at the establishment of the People's Republic in 1949.

During the 1950s investment in the province was hampered by Peking's decision to emphasize inland rather than coastal provinces and by conflict in the Taiwan Strait, which made the national government hesitant to invest in a potential war zone. Fukien's share of investment was smaller than that of any other province. Gradually, however, for strategic and developmental reasons, the economy began to grow, and regional centres, particularly in the Min Valley, developed. Nan-p'ing became a key forest-products centre, acquiring one of the country's advanced pulp and paper plants. San-ming became the site of a medium-sized iron and steel plant drawing on local coal and iron reserves. The development of a major cement plant at Shun-ch'ang laid the foundation for the local building materials industry.

Economic growth

Provincial economic growth increased markedly with the shift in government policy toward favouring the development of coastal trading cities. Fukien and Kwangtung were given special powers in 1979 to attract foreign investment, particularly in export industries, and to establish special economic zones for that purpose. One such zone was set up in northwest Amoy in the 1980s to develop industrial sites and support infrastructure for the zone. The effect was to double the harbour capacity of Amoy.

A second reform was the creation of a south Fukien special economic zone, similar to the Shanghai and Pearl River Delta zones, designed to orient regional development in southernmost Fukien toward the production of light industrial goods for export. A similar pattern of development is also affecting Fu-chou, which was designated one of China's "open" cities in 1984 and which has been working to establish an economic and technical development zone near the port city of Ma-wei.

Transportation. From the Korean War and the partial blockade of the Fukien coast by the United States and by Chinese Nationalist forces based on Taiwan, overseas trade was virtually halted. Fukien's trade patterns consequently turned inland, especially after the completion in 1955 of the Amoy–Ying-t'an railway, which crosses the Wu-i range to link the province with the Chinese national rail network. Fukien's traditional isolation has also been breached in recent years by the construction of modern highways, linking it to neighbouring Kiangsi and Chekiang provinces. Air services centre on the chief airport at Fu-chou.

Fukien's rivers are still in use for transportation. The headwaters of the Chin River, a tributary of the Fu-t'un River, are navigable for small boats right up to the Wu-i Mountains, despite the river's rocky channel and many rapids; boats bring downstream the tea grown on the slopes of the mountains. Below Chien-ning, larger boats of special construction are employed for the tea trade.

Administration and social conditions. *Government.* The original leadership of the province was drawn from the ranks of the 1920s local guerrilla movement and from the soldiers of the 3rd Field Army, which took control in 1949. They were displaced in the turmoil of the Cultural Revolution, which badly affected the province. After the late 1970s a new leadership emerged with a more technocratic and development-oriented character. Within provincial jurisdiction are five prefectures (*ti-ch'ü*) and four prefecture-level municipalities (*shih*). Below that level are counties (*hsien*) and county-level municipalities (*shih*).

Education. One of the most notable institutions of higher learning in Fukien is Amoy University. Fu-chou, famous since the Sung dynasty as a cultural centre, is the site of Fu-chou University, Fukien Medical College, Fukien Agricultural Institute, Fukien Normal College, and the Fukien Institute of Epidemiology of the Chinese Academy of Medical Sciences. Illiteracy has generally been eliminated among those persons born since 1950.

Health and welfare. Public health has improved considerably since the establishment of the People's Republic, and malnutrition has not been reported for decades.

Cultural life. Traditional Chinese culture reached a high level in Fukien during the Sung period (960–1279). Certain unique traditional customs evolved that gave women a stronger social position than that of the women in North China. The province's long literary tradition centres about local history recorded during the last thousand years.

At least two distinct provincial subcultures persist to this day, reflecting linguistic and historical differences among Fukien's regions. The Min-pei, or northern section of

Fukien centred on Fu-chou, was an early centre of Buddhism and, because of close contact with Japanese culture through the Ryukyu Islands, still shows some of those influences in culture and cuisine. As the centre of administration, the Min-pei has a more conservative tradition and, with its seafaring history, has historically supplied many of China's greatest naval officers.

In contrast, the Min-nan, or southern Fukien, centred on the Amoy–Chang-chou–Ch'uan-chou triangle, has the reputation of being more commercial, adventurous, and hardworking. With strong linguistic differentiation, it is home to a rich operatic and balladic tradition of its own. Much of the modern history of the region has been shaped by the close continuing contact between Min-nan peoples and their overseas relatives, who set down roots in Southeast Asia from the 16th century onward.

Fukien cuisine is considered to be one of China's five main regional cooking styles, though it is not well known outside China. Fukien is also known for its strong educational tradition. During the Ming and Ch'ing dynasties many of China's great statesmen and scholars came from the province.

HISTORY

Early history

The area now called Fukien was first referred to in the *Chou li,* a classic that may date to the 12th century BC, although modern scholars believe it to have been written at a much later date. In this classic the seven Min tribes are mentioned together with "eight barbarian peoples" in the south.

During the latter part of the Ch'un-ch'iu (Spring and Autumn period; 770–476 BC) one of the feudal states within the China area was the kingdom of Yüeh, located south of Hang-chou Bay; it included what is now Fukien Province. The lord of Yüeh was nominally a vassal (viscount) of the Chinese king. The Yüeh and their culture are considered by some to have constituted one of the principal elements that merged to form the contemporary Chinese ethnic and cultural complex.

During the last quarter of the 5th century BC, Yüeh became a powerful kingdom after its conquest of the state of Wu (473 BC) to its north. During the era known as the Chan-kuo ("Warring States") period, Yüeh was, in turn, conquered by the kingdom of Ch'u (*c.* 334 BC) to the northwest. Wu-chu, one of the sons of the vanquished Yüeh king, fled by sea and landed near Fu-chou to establish himself as the king of Min-yüeh. When the first emperor of the Ch'in dynasty conquered the kingdom of Ch'u in 223 BC, the Chinese domain was finally unified within the bounds of a monolithic state. Li Ssu, the famous prime minister of Ch'in, deposed the king of Min-yüeh, establishing instead a paramilitary province there called Min-chung Chün. The collapse of the Ch'in dynasty (206 BC) was followed by the war between the famous general Hsiang Yü and the crafty Kao-tsu, the founder of the Han dynasty. Wu-chu, the deposed king of Min-yüeh, sided with Kao-tsu, who defeated his rival and became emperor of China; he reestablished Wu-chu as the king of Min-yüeh, which consisted roughly of the present area of Fukien. During the reign of the emperor Wu-ti (141/140–87/86 BC) a rebellion by the Min-yüeh tribes was put down, and the tribes were resettled in the inland region far to the north between the Huai and Yangtze rivers.

During the Six Dynasties period (AD 220–589) the region remained in the Chinese domain, but true Sinicization did not come about until the T'ang dynasty (618–907). After the fall of the T'ang, the territory of Fukien reemerged as the kingdom of Min, with its capital in Fu-chou. In the mid-10th century it was subdivided into the state of Yin, controlling the Min-pei, and the state of Min, controlling southern Fukien from Chang-chou. The province grew rapidly in importance as the economic hinterland of the Nan (Southern) Sung capital, Lin-an (modern Hang-chou). The province became a key supplier of rice to the region following the introduction of a fast-ripening variety called Champa rice from Southeast Asia. It also became the major producer of sugar, fruit, and tea. Because of the importance of trade to the Nan Sung, the province also was important as a shipbuilding and commercial centre for both overseas and coastal trade. The port of Ch'üan-chou, known to Marco Polo as Zaitun, was one of the world's great ports in this period.

Marco Polo's port of Zaitun

The province's decline began with the Ming dynasty ban on maritime commerce in 1433 and was reinforced by the Ch'ing dynasty's policy of isolation, which particularly affected the province in the late 17th century, when Ming dynasty loyalists occupied Taiwan and the islands off Fukien. There was some revival of the economy in the mid-19th century with the opening of Fu-chou and Amoy as treaty port cities, but the modern shipbuilding industry established at Ma-wei by the Ch'ing was destroyed by a French fleet during the Sino-French War of 1883–85.

In the aftermath of the revolution of 1911–12, Fukien was a pawn in local warlord struggles and was divided into political and military fiefdoms. In the early 1930s part of western Fukien was incorporated into the Communist-controlled territory of the Kiangsi Soviet. In 1933 a revolt of government troops stationed in the province against the Nanking government led to assertion of Nanking government control over the province and to the expulsion of Communist forces. After 1938 the Japanese occupied the coastal centres of the province, while the provincial government retreated inland to Yung-an in central Fukien, where it administered the interior of the province for the remainder of the war. In 1949 the Communist-led 3rd Field Army took control of the province. (F.Hu./V.C.F.)

Hai-nan

The province of Hai-nan (Hai-nan in Wade–Giles romanization, Hainan in Pinyin), the name of which means "South of the Sea," is coextensive with Hai-nan Island. Hai-nan is located in the South China Sea, separated from Kwangtung's Lei-chou Peninsula to the north by a shallow and narrow strait. It is the southernmost province of China and, with an area of about 13,200 square miles (34,300 square kilometres), is also the smallest. For centuries Hai-nan was part of Kwangtung province, but in 1988 this resource-rich tropical island became a separate province. The capital is Hai-k'ou (Pinyin: Haikou).

PHYSICAL AND HUMAN GEOGRAPHY

The land. Hai-nan's long coastline of more than 930 miles (1,500 kilometres) contains numerous bays and natural harbours. Alluvial plains cover a narrow coastal margin, reaching their broadest point in the northeast. The southern interior of the island is mountainous, with Mount Wu-chih rising to over 6,000 feet (1,830 metres) above sea level. Numerous rivers and streams cascade out of the mountains; the longest, the Nan-tu River, flows northeastward.

Climate

Hai-nan's climate is tropical. Temperatures average about 64° F (18° C) in January and 84° F (29° C) in June. Rainfall is heavy especially in summer, with an average annual precipitation of about 70 inches (1,800 millimetres) in the south and 60 inches in the north. The northeastern lowlands can sustain three crops of rice per year.

The island is covered with mature red soils. The natural vegetation, which has been much reduced, includes many palms, bamboos, rattans, and tropical hardwoods. The mountain belt, especially in the east, is covered with dense tropical rain forest up to an elevation of about 2,600 feet. Animal life is rich and varied and includes deer, gibbons, and blind snakes; Hai-nan's streams and offshore waters abound in fish.

The people. Two-thirds of Hai-nan's predominantly rural population is concentrated in the northeastern lowlands. Most of the people are Han (Chinese), but about one-sixth are ethnic minorities. The Li, concentrated in the south, constitute the largest minority group, followed by the Miao. The largest cities are Hai-k'ou in the north and the port city of Ya-hsien (locally called San-ya) in the south. The lingua franca of Hai-nan, Hainanese, is a variant of the southern Fukien dialect.

The economy. Hai-nan's economy is predominantly agricultural, and more than two-thirds of the island's exports are agricultural products. Hai-nan's elevation to province-level status, however, was accompanied by its

designation as China's largest "special economic zone," the intent being to hasten the development of the island's plentiful resources. The central government has encouraged foreign investment in Hai-nan and has allowed the island to rely to a large extent on market forces.

Hai-nan has commercially exploitable reserves of more than 30 minerals. Iron, first mined by the Japanese during their occupation of the island in World War II, is the most important. Also important are titanium, manganese, tungsten, bauxite, molybdenum, cobalt, copper, gold, and silver. There are large deposits of lignite and oil shale on the island, and significant offshore finds of oil and natural gas have been discovered. Virgin forests in the interior mountains contain more than 20 commercially valuable species, including teak and sandalwood.

Agriculture and fishing. Paddy rice is cultivated extensively in the northeastern lowlands and in the southern mountain valleys. Leading crops other than rice include coconuts, palm oil, sisal, tropical fruits (including pineapples, of which Hai-nan is China's leading producer), black pepper, coffee, tea, cashews, and sugarcane. In the early 20th century Chinese emigrants returning from Malaysia introduced rubber trees to the island; after 1950, state farms were developed, and Hai-nan now produces most of China's rubber.

Rubber production

Harvesting coconuts on Hai-nan Island, Hai-nan Province.
Pan Jiamin—New China Pictures

Marine products contribute a significant share to the provincial economy. Shrimps, scallops, and pearls are raised in shallow bays and basins for local use and export. Grouper, Spanish mackerel, and tuna constitute the bulk of the catch from the rich offshore fishing grounds.

Industry. Hai-nan's industrial development largely has been limited to the processing of its mineral and agricultural products, particularly rubber and iron ore. Since the 1950s, machinery, farm equipment, and textiles have been manufactured in the Hai-k'ou area for local consumption. A major constraint on industrial expansion has been an inadequate supply of electricity. Much of the island's generating capacity is hydroelectric, and it is subject to seasonal fluctuations in stream and river flows.

Transportation. Before 1950 there were practically no transportation links with the interior of the island. The Japanese built a railroad from the iron mines in the southwestern mountains to the coast, which subsequently was upgraded and extended around the southern coast, but there is no link with Hai-k'ou in the north. The first roads were built in the early 20th century, but no major road construction was undertaken in the mountains until the 1950s. Parallel north–south roads along the east and west coasts and through the interior of the island constitute most of Hai-nan's road network. The freight-handling facilities of the island's ports have been improved, and Hai-k'ou has an international airport.

Government. Even while Hai-nan was a part of Kwangtung it had a considerable amount of local autonomy; the southern half of the island was an autonomous prefecture (*tzu-chih-chou*). Hai-nan's elevation to provincial level increased its accountability to the central government, but by designating the new province a special economic zone the central government expressed its intent to allow Hai-nan maximum flexibility in devising programs to facilitate foreign investment and economic growth. Administratively, the province has been divided into five economic districts.

Cultural life. Hai-nan has always been on the fringe of the Chinese cultural sphere. Traditionally, the island was a place of exile for criminals and disgraced officials. As a frontier region celebrated by such exiled poets as Su Tung-p'o, Hai-nan acquired an air of mystery and romance. The influx of large numbers of mainlanders after 1950—particularly in the 1970s, when young Chinese from southern Kwangtung were assigned to state farms to help develop Hai-nan, and in the 1980s, when thousands more came to take advantage of the economic opportunities offered—has perpetuated the frontier atmosphere on the island. The level of primary and secondary education has improved since 1949, but facilities for higher education remain inadequate.

Education

HISTORY

Hai-nan was formally incorporated into the Chinese empire in 110 BC, when the Han government established a garrison in the north. Chinese sovereignty remained nominal, however, until the T'ang dynasty (AD 618–907). During the Yüan (Mongol) dynasty (1206–1368) it became an independent province, at which time it acquired the name Hai-nan. In 1370, however, it became a part of Kwangtung. Hai-nan's first major period of settlement occurred in the 16th and 17th centuries, when large migrations from Fukien and Kwangtung pushed the island's indigenous peoples into central and southern Hai-nan.

In 1906 the Chinese Republican leader Sun Yat-sen proposed that Hai-nan become a separate province, and for a short time (1912–21) it was nominally independent under the name Ch'iung-yai Island. The Japanese occupied Hai-nan (1939–45) during World War II and began developing the island's resource potential. Hai-nan reverted to the Chinese Nationalists in 1945 and was one of the last places to fall to the Communists.

After 1950 Hai-nan served as a military outpost and as a source of raw materials, but because of its strategic vulnerability the central government was reluctant to make it an investment priority. With China's shift in economic policy at the end of the 1970s, Hai-nan became a focus of attention. In 1984 the island was designated as a special zone for foreign investment; and, though it was still part of Kwangtung, it was upgraded to the status of a self-governing district, a prelude to its establishment as a province in 1988. (V.C.F.)

Hong Kong Special Administrative Region

For coverage of the Hong Kong Special Administrative Region, see HONG KONG.

Hunan

Hunan (Hu-nan in Wade–Giles romanization, Hunan in Pinyin) is a landlocked province of China, covering an area of 81,300 square miles (210,500 square kilometres). A major rice-producing area, Hunan is situated to the south of the Yangtze River Basin. It is bounded by the provinces of Hupeh to the north, Kiangsi to the east, and Kwangtung to the southeast, by the Chuang Autonomous Region of Kwangsi to the southwest, and by the provinces of Kweichow and Szechwan to the west. The name Hunan is formed from the Chinese words *hu* ("lake") and *nan* ("south"), meaning the land to the south of the lakes

that reach from Sha-shih, Hupeh, to Chiu-chiang, Kiangsi. The capital and most important city of the province is Ch'ang-sha, situated in the northeast, on the banks of the Hsiang River.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* More than one-quarter of the terrain lies at a height of more than 1,640 feet (500 metres), and much of it is well over 3,000 feet above sea level. The highlands in the west run from northeast to southwest, forming the eastward edge of the Kweichow Plateau, whose extension, the Hsüeh-feng Mountains, lies in the heart of the province. These mountains are composed mainly of slate, quartzite, and sandstone, deeply incised by river valleys. The Nan Mountains in the south run from east to west at altitudes of between 500 and 3,300 feet, forming a broad mountain border between Hunan, Kwangtung, and Kwangsi. They are largely dome-shaped and granitic, although limestone and red clay are found in lower-lying areas. In the east the mountain ranges of Chu-kuang and Wu-kung form the border with Kiangsi. The Chu-kuang Mountains, in the extreme southeast of the province, rise to a height of 6,600 feet.

The uplands of the west, south, and east fall steadily in altitude toward the plain of Tung-t'ing Lake in the north, which is contiguous with the Hupeh Plain and forms part of the floodplain of the Yangtze River. The part of the plain within the borders of Hunan has an area of 3,800 square miles; it has been formed by silt carried down from the mountains by the Yangtze and its right-bank tributaries. Tung-t'ing Lake is a broad and shallow seasonal lake, consisting of the remnants of a former inland sea that once filled the Yangtze Basin. Its area varies considerably between summer and winter, and the lake has dried up considerably since the 1950s.

Tung-t'ing Lake

Drainage. Hunan's entire river system drains into Tung-t'ing Lake, with the exception of the Lin Stream, which divides into two parts, with one distributary draining directly into the Yangtze River and the other into Tung-t'ing Lake. The western highlands are drained by the Yüan River and by the Tzu and Li streams. The Yüan and Tzu are torrents in their upper courses; fast-flowing in summer, they run through deep gorges, broadening out to wider valleys in their lower courses. Hunan's largest river, the Hsiang, rises in the heart of the Nan Mountains, as do its tributaries. Many smaller rivers that rise in the mountains along the eastern border flow westward to join the Hsiang in its northward course.

Much of the low-lying land around Tung-t'ing Lake is subject to flooding when the rivers come down in spate during the summer months. The system of dikes built to contain the floodwaters is supplemented by a vast network of electric pumping stations. These pumps drain the fields when waterlogged and irrigate them in times of drought. In the dry hill lands, numerous large and medium-sized water-control projects have been built. In these projects, valleys are dammed and "mountain pools" formed, from which channels are led to the arid land. One of these schemes—the Shao-shan Irrigation System—diverts some of the upper waters of the Lien Stream, thus irrigating the dry hill land, and also controls flooding in the river's lower reaches; the irrigated area has been converted from single-crop to double-crop rice land.

The Shao-shan Irrigation System

Soils. The soils of the province are largely pedalferic (rich in alumina and iron) and are mainly lateritic (leached, iron-bearing) yellow earths or red clays. In the hilly regions of central and southern Hunan, the soils are for the most part lateritic clays that are strongly acidic and poor in organic material. The alluvial soils of the northern plains are less acidic and are used for growing rice.

Climate. The north generally experiences more extreme weather conditions than does the south. In winter, occasional waves of cold air from Mongolia sweep southward, injuring tea bushes and fruit trees in northern Hunan. The average minimum winter temperature is 43° F (6° C). Summers are long and humid, the average maximum summer temperature being 86° F (30° C). The north has an average of 260 frostless days a year, while in the south the average is 300 days. Rainfall is ample, with the maximum precipitation occurring between spring and summer. The total annual rainfall of 56 inches (1,422 millimetres) decreases from south to north. Hunan lies in the path of cyclones that pass from west to east along the Yangtze Basin in summer, bringing with them at times long periods of heavy rain, resulting in extensive flooding of low-lying lands.

Plant life. The natural vegetation of Hunan was originally dense deciduous and coniferous forest. Over the centuries, as the population has increased, all the lowlands and much of the highlands have been cleared to make way for cultivation. Despite this vast deforestation, however, large stands of pine, cedar, bamboo, and camphor are found in the western highlands. Other important trees and shrubs include tung (from which tung oil is obtained), tea (from which tea seed oil is obtained), and liquidambar. Bamboo groves planted along the roadsides are characteristic of Hunan and supply the province's craft industries. As elsewhere in central and southern China, groves of bamboo, camphor, and cedar are usually found around villages, contributing greatly to the charm of the countryside.

Settlement patterns. Villages are usually small, and it is not unusual for an entire village to belong to one extended family, from which the settlement takes its name. Most of the farms on the plain south of Tung-t'ing Lake are built on islands of Yangtze alluvium, protected by dikes from summer flooding.

Three of the largest cities, Ch'ang-sha, Hsiang-t'an, and Chu-chou, lie close together at the intersection of road, rail, and river communications along the Hsiang River. Other large cities include Heng-yang, the economic and communications centre of southern Hunan, and Ch'ang-te, the marketing centre for the Yüan River Basin.

The people. The overwhelming majority of the population is rural. The population is primarily concentrated on the Tung-t'ing Plain and in the main river valleys. Almost all of the people are Han (Chinese). In addition, some minority peoples, mainly of four tribes—the Miao, T'u-chia, Tung and Yao—live in the western highlands. The way of life and economy of the Miao and the T'u-chia are similar, and much intermarriage has occurred between them. They live in the southwest, where their economy is based on the cultivation of terraced fields in the foothills and narrow valleys. The Tung inhabit their own autonomous counties in the extreme southwest, with their centres at T'ung-tao and Hsin-huang. Their language, economy, and way of life are similar to those of the Han. The Yao are widely scattered over the mountainous regions of the south and west. They practice dry farming and are known for their expertise in cedar tree culture. Much of their livelihood comes from forestry.

Minority peoples

The Han of the province speak a dialect—Hunanese—that approximates Mandarin quite closely. Radio broadcasting has had the effect of slowly reducing differences in local dialects, which can be considerable. The minority languages were unwritten until missionaries devised scripts for some of them, such as the Samuel Pollard script for the Miao language. Since 1949 these scripts have been revised, extended, or replaced by a phonetic script, based on the Latin alphabet, that is akin to the Pinyin script adopted for the Mandarin language of the Han. There is growing literacy among the Miao and Tung peoples. The interweaving of Confucianism, Buddhism, and Taoism, as well as Islām and Christianity, are complicated.

The economy. *Agriculture.* Although mining and industry have been developed since 1949, Hunan's economy remains mostly agricultural. Hunan ranks first among China's provinces in rice production. Most of Hunan's arable land is farmed using modern techniques, including mechanized irrigation and chemical fertilization. Most farms are small, however, and mechanization has been confined to the use of simple machines and tools, such as rice transplanters, foot-operated rice-threshing machines, and a tube water raiser that is replacing the old wooden trough and paddles.

Hunan consistently ranks first nationally in rice output and exports a large surplus to other provinces. It is estimated that most of the province's cultivable land is

Rice production

Terraced paddies in Hunan Province, one of the leading producers of rice in China.

devoted to paddies (rice fields), a great many of which in the south produce two crops of rice per year and demand careful cultivation. The first crop is planted at the end of April and harvested at the end of July; the second crop is harvested in November. Autumn is the most difficult period, as decreasing rainfall and increasing evaporation necessitate continuous irrigation. With improved irrigation, a decreasing amount of rice is grown on fields where the crop relies totally on rainfall. Introduction of hybrid rice varieties has further increased production. Other food crops include sweet potatoes, corn (maize), barley, potatoes, kaoliang (a variety of grain sorghum), buckwheat, garden peas, millet, and horsebeans.

Among the industrial crops, rape—an herb grown for its seeds—is cultivated mainly in the upper valleys of the Hsüeh-feng Mountains, while ramie (a shrub that yields a fibre used in textile manufacture), cotton, and jute are produced around Tung-t'ing Lake. Red and black tea are grown on the foothills of the Hsüeh-feng Mountains and on Mount Mu-fu on the eastern border. Peanut (groundnut) cultivation is widespread, and tung trees and tea seed shrubs are grown for their oils in the western and southern highlands. A variety of fruits is grown throughout the province, including citrus, pears, peaches, and chestnuts.

During the early 20th century, heavy and wasteful cutting of Hunan's timber reserves occurred. Since then, stricter control of cutting has been enforced, and some reforestation has been carried out. Fish are taken in large quantities from lakes, rivers, and village ponds. The most common varieties are carp, silver carp, and "silver fish." The full exploitation of fishpond culture was developed in the early 1970s. Cattle, including water buffalo, are used almost exclusively for draft purposes. Hogs are concentrated mainly in the central and eastern areas, where the population is densest. The swine industry is a significant source of rural cash income.

Industry. Hunan's considerable mineral wealth includes ample coal reserves; iron ore, tin, and manganese deposits; rich deposits of antimony; and lead, zinc, tungsten, molybdenum, bismuth, niobium, and tantalum. More than half of the province's electric power is produced by hydroelectric power stations.

The main coal measures are located in the south. Coal was little developed before 1949, but production rose substantially as a result of the opening of large mines north of Ch'en-hsien in the extreme south. These mines serve the ironworks and steelworks at Wu-han in Hupeh. Iron ore is widely distributed, and there is a long-established local industry that produces iron cookware. The main iron mines are located in the hills east and south of Ch'ang-sha and Hsiang-t'an. Development of the iron and steel industry is centred in the triangle formed by the three large cities of Ch'ang-sha, Hsiang-t'an, and Chu-chou. Antimony production is centred on Hsin-hua, northwest of Shao-yang. Hunan is one of China's largest producers of tungsten; it is chiefly mined in the hills between the Tzu and Yüan rivers around Yüan-ling.

Plants producing iron and steel, processed foods, and electrical equipment are located in Hsiang-t'an, while Chu-chou is the centre of large-scale heavy industry and hog exports. Ch'ang-sha is Hunan's centre for light industry, which includes rice milling, food processing, aluminum smelting, and the manufacture of machine tools, bearings, and textiles. It is also famous for its handicrafts, which include *hsiang* (border) embroideries, duck-down quilts, umbrellas, and leather goods. I-yang—known as "the Bamboo Town"—is typical of many of the smaller towns specializing in one particular handicraft. Nearly everything required in domestic life—from beds to scrubbing brushes—is made from bamboo.

I-yang, the Bamboo Town

There are several famous pottery kilns in the province that date back to the T'ang dynasty (618–907). Situated at Yüeh-yang (Yoyang), Hsiang-yin, and near Ch'ang-sha, these kilns have at different epochs produced all sorts of wares, according to the market of the period. Their fortunes have fluctuated through the centuries. More recently, they have increased their output, especially in the Hsiang-yin kilns, which produce large quantities of crockery for the general market.

Transportation. Hunan stands at the crossroads of China's historical lines of communication—the great waterway of the Yangtze River, which flows from Szechwan Province to the sea, and the Imperial Highway, running from Canton northward to Peking.

Railway construction began in 1912, and the first line was between Wu-han and Chu-chou; it was eventually extended south to Canton and is now part of the major Peking–Canton trunk line. There is a junction at Heng-yang leading to Kwangsi, from where the line continues south to Hanoi. From Chu-chou, the Che–Kan Railway runs east to Kiangsi Province and also to Chekiang and Fukien on the east coast. Another railway runs from Hsiang-t'an westward to Kweichow Province, opening up the hitherto remote western lands, and a second north–south line has been built through western Hunan.

Water and road transport

Shipping is another important means of transportation, as about one-fourth of Hunan's goods are moved by water. Traffic on the Hsiang River is the most important. Tung-t'ing Lake has innumerable shallow waterways connecting four main rivers. Yüeh-yang in the northeast corner of the lake is the collecting centre for the timber rafts that sail the Yangtze River to Wu-han. One main trunk road runs

from north to south, following the Peking–Canton railway into Kwangsi. Three other main routes run from east to west and are of growing importance because they open up areas not served by the railways.

Administration and social conditions. *Government.* From 1950 to 1954 Hunan was part of the South Central China greater administrative region, which extended from Hupeh in the north to Kwangtung and Kwangsi in the south. In 1954 provincial (*sheng*) government throughout the country was made directly subordinate to the national government. Since then the province's administrative structure has gone through several changes. It is now divided into eight prefectures (*ti-ch'ü*), six prefecture-level municipalities (*shih*), and one autonomous prefecture (*tzu-chih-chou*). Below that level are counties (*hsien*) and county-level municipalities (*shih*).

Health and welfare. Emphasis is laid on preventive medicine. After 1949, public health teams were sent into the country to vaccinate and inoculate and to advise on and supervise public hygiene. Debilitating diseases such as malaria and schistosomiasis—a disease of the blood and tissues that is spread by larvae in the droppings of animals in the rice fields—have been attacked, and since 1949 there has been a marked fall in infant mortality and an increase in life expectancy.

Cultural life. Although the aim of the government is to promote linguistic uniformity, Hunanese—which was Mao Zedong's (Mao Tse-tung's) own dialect and is fairly akin to Mandarin—persists.

Education

Before the revolution, Western learning was largely acquired through Christian missionary or other Western-style schools, and most of the population remained illiterate. Since 1949 a countrywide literacy drive has been pursued with vigour and enthusiasm and a large measure of success. By the 1980s Hunan had one of the lowest illiteracy rates in the country. Ch'ang-sha has retained its historic role as the province's cultural and educational centre and is the location of technical institutes, teacher-training colleges, and institutes for minorities.

HISTORY

From 350 to 221 BC Hunan formed the southernmost extension of the state of Ch'u, which nominally was ruled by the Chou dynasty. From 221 to 206 BC Hunan was ruled by the Ch'in dynasty, which subdued contending feudal states and joined them into the first unified state of China, of which Hunan formed part of the central area. Most of Hunan at this time was covered with dense primeval forest that was sparsely inhabited by tribes who engaged in hunting, fishing, and clearing land by burning or cutting for temporary cultivation. These tribes also mined the copper and tin that were used in the north for making bronze.

After the downfall of the Ch'in dynasty, the area became quickly incorporated into the Chinese empire ruled by the Han dynasty from 206 BC to AD 220. During this

Early migrations

period persistent waves of migrant Han (Chinese) from the North occupied the land, and the indigenous Miao, T'u-chia, Tung, and Yao were pushed west and southwest into the hills, which they still occupy. By the end of the Hsi (Western) Chin dynasty in AD 316/317, the Tung-t'ing floodplain to the north and the Hsiang Valley in the east were relatively well populated. Han migration from the North continued under subsequent dynasties, with migrants fleeing first from Mongol and then from Manchu invasions. Those who went farther south, crossing the Nan Mountains in the southern part of the province to enter Kwangtung, have since considered themselves T'ang-jen, or southern Chinese, but the Hunanese have remained Han in both culture and speech.

Population pressures on the land increased markedly in the 19th century during the latter part of the Ch'ing, or Manchu, dynasty (1644–1911/12), leading to increased peasant unrest, particularly among the non-Chinese tribes. When the Taiping Rebellion broke out in Kwangsi in 1850, it spread northward into Hunan. Hunan, together with other provinces on the lower Yangtze Basin, was desolated in the subsequent fighting, although the city of Ch'ang-sha withstood a Taiping siege in the mid-1850s. It was a Hunanese, Tseng Kuo-fan, who ultimately was responsible for crushing the rebellion.

Hunan was not opened to foreign trade until 1904, following the conclusion of the Treaty of Shanghai between China and Japan. A foreign settlement was established at Ch'ang-sha, and British and Japanese firms built warehouses. Hunan became a centre of revolutionary activity: the first uprisings against Yüan Shih-k'ai's attempted regency over the Chinese empire occurred in the province in 1910, although the more widespread revolution that finally overthrew the tottering Manchu dynasty and established the Republic of China did not occur until the following year. Thereafter, Hunan remained in a state of unrest from which it had little respite until 1949, when the People's Republic of China was established. Many important Chinese Communist leaders—including Mao Zedong, who was born in Shao-shan, near the border with Kiangsi, and Liu Shaoqi (Liu Shao-ch'i), chairman of the People's Republic (1959–68)—were from Hunan. Mao was largely responsible for encouraging the peasants and miners to make the abortive Autumn Harvest Uprising of 1927. He subsequently held the Communist forces together in the Ching-kang Mountains, where they withstood repeated attacks by the forces of Chiang Kai-shek, the Chinese Nationalist leader. In 1934 Mao set out from the Hunan–Kiangsi border region, leading his forces westward in the difficult northward retreat that later came to be known as the Long March.

The years of unrest (1910–49)

During the Sino-Japanese War Hunan was the scene of bitter fighting between 1939 and 1941. After the fall of Hunan to the Japanese, the Nationalist general Hsüeh Yüeh continued to successfully defend Ch'ang-sha against the Japanese invaders, until it too fell in 1944. Between 1946 and 1949 the province was relatively peaceful. In 1949, despite damage to bridges and communications, the province experienced comparatively little destruction when the Nationalist forces retreated rapidly southward before the advancing Communist armies.

Provincial leaders from Hunan have played an important national role since 1949. Hunan's provincial party leader was purged in 1958 for opposing the economic policies of the Great Leap Forward (1958–60) and was replaced by supporters of Mao Zedong's more ambitious and radical policies. One of Mao's rising provincial supporters, Hua Guofeng (Hua Kuo-feng), was Communist Party chairman (1976–81) after Mao's death.

Hunan supported many of the policies of Mao's Cultural Revolution (1966–76), and it was slower than other provinces at implementing the economic and political reform programs instituted by the post-Mao leadership. Gradually, however, the provincial leadership has been replaced by more technically proficient and younger leaders, who are taking over from the revolutionary generation.

(T.R.T./V.C.F.)

Kiangsi

Kiangsi (Chiang-hsi in Wade–Giles romanization, Jiangxi in Pinyin), a province of China occupying a south central location, is bounded by the provinces of Hupeh and Anhwei on the north, Chekiang and Fukien on the east, Kwangtung on the south, and Hunan on the west. The area of the province is 63,600 square miles (164,800 square kilometres). On the map its shape resembles an inverted pear. The port of Chiu-chiang, 430 miles (692 kilometres) upstream from Shanghai and 135 miles downstream from Han-k'ou, is the province's principal outlet on the Yangtze River. The provincial capital is Nan-ch'ang.

The name Kiangsi means "West of the (Yangtze) River," although the entire province lies south of it. This seeming paradox is caused by changes made in administrative divisions throughout China's history.

Kiangsi's strategic location

Lying in the midst of a longitudinal depression between China's western highlands and the coastal ranges of Fukien Province, Kiangsi constitutes a corridor linking the province of Kwangtung, in the South, with the province of Anhwei and the Grand Canal, in the North. Throughout China's history, Kiangsi has played a pivotal role in national affairs because of its position astride the

main route of armies, commerce and trade, and large population migrations.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Topographically, Kiangsi corresponds to the drainage basin of the Kan River, which runs northeastward in descending elevation from the southern tip of the province to P'o-yang Lake and the Yangtze in the north. This basin is surrounded by hills and mountains that rim the province from all sides. Among the more important ranges are the Huai-yü Mountains, to the northeast; the Wu-i Mountains, to the east; the Chiu-lien and Ta-yü ranges, to the south; the Chu-kuang, Wan-yang (including Mount Ching-kang), Wu-kung, and Chiu-ling ranges, to the west; and the Mu-fu and Lu ranges, to the northwest. A remarkable feature of these mountains is that they rise in disconnected masses and thus contain corridors for interprovincial communication, especially along the Hunan border. The mountains to the south, too, present no formidable barrier. The Mei-ling Pass is a broad and well-paved gap leading to Kwangtung Province.

Other mountains are found in the centre and north of the province. East of the Middle Kan Valley are the Yü Mountains. Made up of short and moderate hills separated by a network of streams, the country traversed by this range consists of a succession of small valleys with bottomlands from five to 12 miles wide. The Lu Mountains, in the north, rise sharply to almost 5,000 feet (1,524 metres) from the lowlands west of P'o-yang Lake.

You Yungu—Eastfoto

Pine tree overhanging peaks in the Lu Mountains in northern Kiangsi Province.

Rivers

Drainage. The principal river of Kiangsi is the Kan, which traverses the entire province from south to north. Its headwaters are two streams that converge to form one river at Kan-chou. Along its course this great river receives several large tributaries from the west and a lesser number of smaller tributaries from the east.

Besides the Kan, other rivers of Kiangsi form distinct basins of their own in the northeastern and northwestern parts of the province. These include the Hsin River, which rises near Yü-shan in the northeast and runs westward to P'o-yang Lake; the Ch'ang and Lo-an rivers, also in the extreme northeast of the province; and the Hsiu River, which, rising in the Mu-fu Mountains in the northwest, drains southeastward into P'o-yang Lake.

Ultimately, all Kiangsi's rivers drain into P'o-yang Lake, which is connected with the Yangtze by a wide neck at Hu-k'ou, a short distance east of the Yangtze port of Chiu-chiang. In summer, when the Yangtze rises, P'o-yang Lake gains in size and depth: its area then covers about 1,800 square miles (90 miles long by 20 miles wide), and its depth averages 65 feet. In winter, when the Yangtze waters recede, it shrinks in size, leaving shallow channels of water in many places. If the high-water stage occurs simultaneously on the Yangtze, the Kan, and other rivers, floods inevitably result. The lake also serves as a useful reservoir.

Soils. The soil in the plains of northern Kiangsi is alluvial and permits intensive cultivation. The hilly lands in other parts of the province have red and yellow soils. In these poorer regions few natural forests have been preserved; commercial trees planted instead include the tea, tung, camphor, bamboo, and pine. On farms with clayey red soils, where the rains have washed away the mineral contents as well as the humus, the soil requires working over and the addition of green manure or chemical fertilizers in order to become productive.

Climate. Situated in the subtropical belt, Kiangsi has a hot and humid summer lasting more than four months, except in spots of high elevation, such as Lu-shan. High temperatures in Nan-ch'ang in July and August average 95° F (35° C). In winter temperature variations between north and south are greater. January temperatures in the north at times fall to 25° F (−4° C), while those in the south average 39° F (4° C). Most of the province has a growing season of 10 to 11 months, thus making possible two crops of rice. Rainfall is plentiful, particularly during May and June. Average annual rainfall is 47 inches (1,194 millimetres) in the north and 60 inches in the south; in the Wu-i Mountains region it can reach 78 inches.

Settlement patterns. Most of Kiangsi's people live in rural areas. The leading city is Nan-ch'ang. Situated on the right bank of the Kan River, a short distance before it enters P'o-yang Lake, Nan-ch'ang is the focal point for rail and river transport, an industrial centre, and a trading centre for agricultural products. Chiu-chiang, on the south bank of the Yangtze 87 miles north of Nan-ch'ang, is the principal port through which the province's products are exported. Just south of Chiu-chiang is the beautiful resort of Ku-ling, perched 3,500 feet atop Mount Lu.

From Nan-ch'ang southward up the Kan are Chi-an, rich in literary lore and the commercial metropolis of the Middle Kan Valley, and Kan-chou, the centre of culture and trade in the Upper Kan Valley. Other cities dot the hinterland on both sides of the river. The leading city in the extreme northeast is Ching-te-chen, the porcelain capital of China. The vast stretch of country east and southeast of Nan-ch'ang contains many cities of historical and commercial importance, the largest of which is Fu-chou. The west and northwest of the province is a focus of heavy and light industry, of which P'ing-hsiang, on the Hunan border, is the major centre.

The people. Kiangsi received successive waves of migration from North China through the ages. Its population is virtually all Han (Chinese); minority groups include the Miao, Yao, and Hui (Chinese Muslim) peoples. The Hakka, descendants of a unique group of migrants from North China, have maintained their separate identity with their own dialect and social customs.

Composition of the population

The language usually spoken is Mandarin, with a marked Lower Yangtze accent, although it has an admixture of the Fukien dialect in regions south of Kuei-hsi and is heavily tinged with the Cantonese accent in the Ta-yü region, south of Kan-chou.

The economy. *Agriculture.* The beautiful basin of the Kan River, together with the valleys of its many tributaries, was one of the nation's most affluent regions before trade patterns were changed by the opening of treaty ports to the Western powers in the mid-19th century. Nevertheless, Kiangsi is still one of China's richest agricultural provinces. Since 1949 the reclamation of unused land, treatment of red soil to make it more fertile, construction of irrigation projects and hydroelectric power stations, and increased use of chemical fertilizers and mechanization

has increased the amount of arable land to more than one-third of the total area of the province.

Principal crops

Food crops produced in Kiangsi include rice, sugarcane, fruits, peanuts (groundnuts), and sweet potatoes. Of these, rice is by far the most important. The P'o-yang Lake plain and Lower Kan and Hsü valleys are the principal areas of rice production; two crops a year are raised in all parts of the province. Kiangsi also produces a great variety of commercial crops: tea is grown on hillsides in many regions; ramie, used for making a fine, silky fabric, is raised south and west of P'o-yang Lake; cotton is grown on the plains northeast of the lake; tobacco is produced in the Chekiang border area; and sugarcane is raised in the northeast and in the south. Other important commercial crops include soybeans, rapeseed, and sesame seeds. Kiangsi is a great provider of fruit, especially citrus, watermelons, pears, and persimmons. The hills of the province also supply the nation's apothecaries with such important herbs as the three-foliaged orange, the greater plantain (*Plantago major*), and the gallnut; and the indigo plant is grown in the valleys east of P'o-yang Lake.

Lush forests in the region from Chi-an southward contain pine, fir, cedar, oak, and banyan. The timber produced there—used for building material and for furniture—is floated down to Chiu-chiang for export to all parts of China. No less important are the camphor tree and the giant bamboo. The timber industry also yields valuable by-products, especially tung oil, resin, turpentine, lampblack (for making Chinese ink sticks), and tea oil.

Livestock raised in Kiangsi include water buffalo, pigs, chickens, and ducks. Inland fishing is a major industry on P'o-yang Lake. In addition, fisheries are found along the numerous rivers and in the almost countless village ponds.

Industry. Although Kiangsi was long known for commerce and handicrafts, modern industry had only a limited base by 1949. Subsequently, however, the province made immense progress in establishing both heavy and light industries. Coal and tungsten are the most important minerals. The area around P'ing-hsiang in the west is the coking coal capital of south central China; another major coal-mining centre is Feng-ch'eng, south of Nan-ch'ang. The region surrounding Ta-yü, on the Kwangtung border, is the centre of tungsten mining, and extensive deposits have been discovered at the extreme southern tip of the province. The ore mined in southern Kiangsi contains 60 percent tungsten; the remaining 40 percent permits the production of sizable amounts of tin, bismuth, and molybdenum. Tantalum, lead, zinc, iron, manganese, copper, and salt are also mined.

Nan-ch'ang is the largest industrial centre; it has plants for a wide variety of heavy and light industrial products. Chiu-chiang has an oil refinery and a petrochemical industry, but it is principally a centre for textile mills and textile machinery. Kan-chou is also a major industrial centre. Food processing is an important enterprise in many localities throughout the province. The development of modern industry, however, has not affected the handicrafts for which Kiangsi has been famous throughout history. The ramie cloth produced in the province continues to be the nation's preferred choice for summer wear. Other important local products are the typical Kiangsi varieties of paper—*lien-shih* paper for printing (made of bamboo), *piao-hsin* paper for wrapping (also of bamboo), and *mao-pien* paper for scribing (made of rice and mulberry straw). Hsü-wan, in the southwest, is a major centre of the engraving and printing industry.

The porcelain industry

The porcelain industry, however, is the foremost activity of the province. During the reign of the Sung emperor Chen-tsung (997/998–1022/23), the town of Fou-liang, in northeastern Kiangsi, was by Imperial decree made a centre for fine porcelain. From that time on, Fou-liang was known as Ching-te-chen, after the Imperial patron's year title Ching-te. For 10 centuries it has supplied the Chinese people with porcelain ware of all descriptions—ranging from items of daily use to artistic works of rare beauty made for the enjoyment of emperors and collectors. The beautiful translucence and hardness of the porcelains from Ching-te-chen are attributable to kaolin (china clay) and petuntse (white briquette), both of which are found in the Ch'ang Valley and along the east shore of P'o-yang Lake. Most of the population of Ching-te-chen is still employed in one way or another in the making of porcelain. The bulk of the output is for domestic trade, although some items are shipped abroad. The government has been making an effort to revive and preserve the secret formulas of the Ming and Ch'ing potters, but the tendency seems to be away from handicrafts and toward mechanization.

Transportation. Kiangsi has an abundance of inland waterways. Most of the rivers flow diagonally, from east and west toward the centre, emptying into the Kan River and P'o-yang Lake; many are navigable. On many shallow streams, as well as on the headwaters of the Kan, navigation is by junk. Thus, there are adequate transportation facilities for all counties of the province; Nan-ch'ang and Chiu-chiang are the main centres for transshipment and distribution. Goods for export are carried by large steamships on the Yangtze.

The first major railroad in Kiangsi, built on the eve of World War I, runs north–south, linking Chiu-chiang with Nan-ch'ang. Another, the Chekiang–Kiangsi railroad, runs east–west, from the Chekiang border, westward to the Hunan border. This line forms part of a national trunk line that extends westward through Hunan into Kweichow to connect with the rail network of the southwest. Another line runs southeastward to Amoy.

Highways

Kiangsi's highways were well developed in the Nationalist period. Many new roads have since been added. The focal centres for the highway system—Nan-ch'ang, Lin-ch'uan, Shang-jao, Chi-an, and Kan-chou—are the hubs of regional road networks and the termini of interprovincial highways.

Administration and social conditions. *Government.* From 1950 to 1954 Kiangsi was part of the Central South greater administrative region. In 1954 Kiangsi Province became directly subject to the central government. Kiangsi's administrative divisions are arranged in a hierarchy of levels. Immediately below the province (*sheng*) there are five prefectures (*ti-ch'ü*) and six prefecture-level municipalities (*shih*). Below that level are counties (*hsien*) and county-level municipalities (*shih*). The lowest political units are the townships.

Education. During the 1950s Kiangsi served as a laboratory for a number of revolutionary educational experiments. Perhaps the most significant innovation in higher education was the Kiangsi Labour University, founded in 1958. It has its main campus in Nan-ch'ang but operates a network of branch campuses, in addition to affiliated technical schools, throughout the province. Aiming at the development of productive work through the dissemination of advanced education, the branch campuses have pioneered a multiplicity of development projects, including building roads in mountainous areas, founding new villages, reclaiming land, building factories, and promoting afforestation.

Centres of higher learning include the Kiangsi branch of the Academia Sinica (Chinese Academy of Sciences), the Kiangsi Library, the Kiangsi Provincial Museum, the Kiangsi Agricultural Institute, and the Kiangsi Medical College, all located in Nan-ch'ang. Popular education has also made advances, and some three-fifths of the population has at least a primary-level education. The adult literacy rate is at the national average.

Health and welfare. Before 1949 the greatest scourge was the prevalence of malaria. This debilitating disease annually took a heavy toll of lives. Since 1949 draining the swamps and pools of stagnant water, the breeding grounds of the disease-carrying *Anopheles* mosquito, and measures taken for epidemic prevention have reduced malaria to a minimum. Another menace to health peculiar to the P'o-yang Lake region was liver fluke (a kind of flatworm). Many thousands of lives were previously lost every year from this parasite, but this disease, too, is rapidly becoming a danger of the past, following mass control of the fluke embryo in the lake and surrounding waters.

Curative medicine

In curative medicine, many improvements have been made. Clinics providing free medical care have been made widely available, while modern hospitals have been established in all cities and counties.

An adequate social welfare program is available. For industrial workers there are measures for accident prevention, as well as insurance programs that provide for hospital treatment, sick leave, disability compensation, maternity leave, and old-age and death benefits. Extra benefits are available based upon cooperation with government policies, such as birth control. In Nan-ch'ang and other industrial towns and in the countryside, the government has constructed new housing and expanded recreational facilities.

Cultural life. For nearly 2,000 years the people of Kiangsi lived under the pervading influence of Confucian culture. With village life rooted in intensive agriculture and government in the hands of the landlord-scholar-officials, the dynamics of society were regulated by Confucian ethics. Such a culture gave the province many famous people. Besides T'ao Ch'ien (a great Chin poet of the reclusive life), Chu Hsi (the Sung dynasty Neo-Confucian philosopher), and Wang Yang-ming (the Ming philosopher), all of whom either taught or lived there, Kiangsi produced a full quota of statesmen during both the Sung and the Ming dynasties.

Yet, despite the dominance of Confucian learning and culture, peasant rebellions also were a strong tradition in the province. The first major revolutionary base of the Chinese Communist Party was at Jui-chin, in southeastern Kiangsi, and an uprising in 1927 at Nan-ch'ang serves as the founding date of the Red Army.

HISTORY

From 770 to 476 BC, during the Ch'un-ch'iu (Spring and Autumn period) of the Chou dynasty, Kiangsi was a part of the kingdom of Ch'u. During the Chan-kuo ("Warring States") period (475–221 BC) the territory east of P'o-yang Lake was annexed by the kingdom of Wu. When a unified empire was established under the Han dynasty (206 BC–AD 220), Kiangsi became the western portion of the large province of Yang-chou and grew rapidly in population and culture.

From 220 to 589, the period of the Six Dynasties, large numbers of families from North China, fleeing the Tatar invaders, settled in Kiangsi. Initially, there were clashes between the northern newcomers and the original inhabitants. In time mutual accommodation prevailed, and the province benefited immensely from the introduction of northern arts, culture, and administrative skills. It was during this period that the Kan River valley became the main highway of the empire. Under the T'ang dynasty (618–907) the growth of commerce and population in Kiangsi was even greater than in earlier times. This was caused first by the opening of the Grand Canal, linking Lo-yang with the Lower Yangtze, and second by a new influx of people from North China. Equally noteworthy was the spread of Buddhism in this period.

Period of Confucian domination

In the Sung dynasty (960–1279) Kiangsi became a model of the Confucian state, governed by scholar-officials. The Pai Lu Tung ("White Deer Grotto") Academy, near Lu-shan, where Chu Hsi taught, became a renowned centre of Confucian learning. From 1069 to 1076 Wang An-shih, a native of Lin-ch'uan, southeast of Nan-ch'ang, was prime minister; Wang introduced reforms to curb the rich and help the poor, only to be overthrown by the conservative champions of the traditional order. In the late Sung period and throughout the era of the Mongol conquest, Kiangsi's cultural and political vigour declined. Such was the obscurantism of the government that it sanctioned a Taoist "papacy" at Mount Lung-hu, near Kuei-hsi, which lasted into the mid-20th century.

In the early years of the Ming dynasty (1368–1644) Kiangsi produced a number of great statesmen, but after a time the government's despotic tax program alienated the people. From the early 16th century onward, peasant brigands living in the hills fought the government. The widespread unrest was ended after the Ch'ing dynasty (1644–1911/12) reunified the country. During this period of prolonged peace Kiangsi again became one of the wealthiest regions of China, but its days of prosperity ended in the mid-19th century, when the Yangtze Valley was devastated by the great Taiping Rebellion against the ruling Ch'ing dynasty and when treaties with the Western powers diverted trade to coastal regions.

In the first half of the 20th century Kiangsi became a focal point for revolution and war. After the 1911–12 revolution the province fell victim to warlord rule, until Chiang Kai-shek brought it under Nationalist control in 1926. Chiang's break with the Communists, however, made Kiangsi a bone of contention between the two sides. An uprising was staged in Nan-ch'ang by the Communists in 1927, followed by the establishment of peasant bases in the southern counties under the Communist leaders Mao Zedong (Mao Tse-tung) and Zhu De (Chu Teh). Such was the growth of their strength that, in 1931, Jui-chin was declared the capital of the Chinese Soviet Republic. In the continuing struggle the Communist guerrillas withstood Chiang's "annihilation campaigns," but his use of an economic blockade forced the Communists to flee Kiangsi and to begin their Long March (1934–35) to northwestern China. Chiang then briefly regained control of southern Kiangsi, and Nationalist government reforms were undertaken on an experimental basis in 1934–37. From 1938 to 1945 much of Kiangsi was under Japanese occupation. The Communists carried on guerrilla activities inside Kiangsi throughout the period.

After the Japanese withdrawal Communist guerrillas dominated the countryside, while the Nationalist government took precarious control of the cities. In 1949 Communist forces crossed the Yangtze from the north and took possession of the province. Kiangsi then entered an era of stability and progress, and many new economic and social developments were pioneered there. (V.C.F.)

Kwangtung

Kwangtung (Kuang-tung in Wade–Giles romanization, Guangdong in Pinyin), the southernmost of the mainland provinces of China, also constitutes the region through which South China's trade is primarily channeled. Kwangtung has an area of 76,100 square miles (197,100 square kilometres) and one of the longest coastlines of any province in China. The province is bounded by the provinces of Hunan and Kiangsi to the north, by Fukien to the northeast, by the South China Sea and the Hong Kong Special Administrative Region to the south, and by the Chuang Autonomous Region of Kwangsi to the west. One foreign holding remains on the coast of Kwangtung—the Portuguese territory of Macao. The capital is Canton (Wade–Giles: Kuangchou; Pinyin: Guangzhou).

Historically Kwangtung and Kwangsi often were jointly governed. Kwangtung was first administered as a separate entity in AD 997; it was from this time that the term Kwangtung (Chinese: "Eastern Expanses") began to be used. Kwangtung has its own physical and cultural identity. Its topography separates it somewhat from the rest of China, and this factor, together with its long coastline, its contact with other countries through its overseas emigrants, and its early exposure to Western influence through the port of Canton, has resulted in the emergence of a degree of self-sufficiency and separatism. Canton dominates the province to an unusual extent.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The surface configuration in Kwangtung is diverse, being composed primarily of rounded hills, cut by streams and rivers, and scattered and ribbonlike alluvial valleys. Together with the Kwangsi region, Kwangtung is clearly separated from the Yangtze River basin by the Nan Mountains, the southernmost of the three major Chinese mountain ranges running from east to west. The greater part of eastern Kwangtung consists of the southerly extension of the Southern Uplands, which stretch down from Fukien and Chekiang provinces. A series of longitudinal valleys running from northeast to southwest extends as far as the vicinity of Canton. Smooth, low hills cover about 70 percent of the province. Most peaks range in elevation from 1,500 to 2,500 feet (450 to 750 metres), with a few reaching 5,500 feet. Level land of any size is primarily found in the alluvial deltas, formed where rivers empty into the South China Sea.

Pearl River Delta

Drainage. Of great extent and importance, the Pearl River Delta, measuring about 3,500 square miles, is marked by hilly outliers and by a labyrinth of canalized channels and distributaries totaling some 1,500 miles in length. The delta marks the convergence of the three major rivers of the Pearl River system—the Hsi (West), Pei (North), and Tung (East) rivers. The Pearl River is the name given to the lower course of the Hsi beyond the confluence. Entirely rain-fed, these rivers, which are subject to extreme seasonal fluctuations, collect so much water that, anomalously, the Pearl system discharges annually six and a half times as much water as the Huang Ho (Yellow River), although its basin area is only about half as large. Altogether, Kwangtung has some 1,300 large and small rivers. The Han is the most important river outside the Pearl system. Other important rivers and lowlands are located in the southwest.

Waterway serving a farming village in the Pearl River Delta region of Kwangtung Province.

Soils. In general, soils are poor, as high temperatures and plentiful rainfall result in podzolization (bleaching) and leaching. Almost all of western Kwangtung is covered with mature red soils, whereas the rest of the province is covered with a mixture of old and young red soils that usually have been subjected to a high degree of podzolization. In the wettest and hottest parts of Kwangtung, lateritic (heavily leached, iron-bearing) soils are common; like the red soils, they do not resist erosion and require substantial fertilization in their cultivation. Yellow soils are found in the wettest and coolest parts of Kwangtung, occurring in small pockets of flatland with imperfect drainage.

Of more limited distribution but of greater economic significance are the alluviums deposited in the river valleys and deltas. As a result of the cultivation of rice, the alluviums have developed special morphological characteristics, the most striking of which is the formation of iron hardpans (hard impervious layers composed chiefly of clay) in the zone of the fluctuating water table.

Climate. Since much of Kwangtung lies south of the Tropic of Cancer, it is the only Chinese province with tropical and subtropical climates. The average July temperature in the Hsi Valley, which is from 82° to 86° F (28° to 30° C), is little different from temperatures in the lower Yangtze and on the Huang Ho, but the average January temperature is considerably higher, ranging from 55° to 61° F (13° to 16° C). Except at higher elevations, frost is rare, so that almost the entire province lies within the area where two crops of rice can be grown. True winter does not occur in the province, but the hot summer varies in length from about 10 months in the south to six months in the north.

The rainfall regime shows a pronounced summer maximum, with the rainy season lasting from mid-April, when Kwangtung starts to be dominated by moisture-laden tropical air masses from the Equator and the Indian Ocean, until mid-October. More than half of the total precipitation falls between June and August. The months between July and September form the main typhoon season, which ordinarily is accompanied by heavy rains and widespread destruction. The driest period is from December to February. Kwangtung's annual rainfall is approximately 60 to 80 inches (1,500 to 2,000 millimetres), decreasing with distance from the coast to the northwest but increasing with altitude and exposure to the prevailing summer monsoon winds.

The typhoon season

Plant life. Abundant moisture, moderate to high temperatures, and variegated physiography support luxuriant and highly diversified plant growth. Broad-leaved evergreen forests, intermixed with coniferous and deciduous trees, originally covered much of the land, while a more tropical type of vegetation predominates on the south coast. With the exception of the more remote mountainous areas, much of this natural vegetation cover has been stripped by fire and by the use of trees and shrubs for fuel. This circumstance, together with millennia of uninterrupted cultivation, has resulted in much of the natural vegetation now taking the form of secondary forests of hardwoods and horsetail pine. On the more severely eroded hills, coarse grasses and ferns have taken hold. Bamboo groves, varying greatly in height and extent, are widespread, particularly in humid river valleys. The most productive and least disturbed forests cover the mountainous areas. Certain trees, notably camphor, have been revered and protected for centuries and are found around grave plots and cultivated fields. Since 1949 massive afforestation programs have been undertaken. In the highlands, where coniferous and deciduous species thrive together, the broad-leaved evergreen forests are characterized by tropical oaks, tan oaks (oaks that yield tannin), and chestnut oaks (or chinquapins). The more significant coniferous species of economic value include horsetail pine, Chinese fir, and Chinese hemlock. Some of the species of cypress and pine are little known outside China. Truly tropical monsoon rain forests are common in the south.

Animal life. Among the mammals found in Kwangtung are many tropical bats, and squirrels, mice, and rats of many species are abundant. Insectivores are generally more diverse than in other regions of China, and carnivores are exemplified by civet cats and small-clawed otters. Types of birds vary according to habitat. In the tropical forest, wildfowl, peacocks, and silver pheasants are common. Reptiles are more restricted in distribution. Kwangtung has a number of pit vipers, including the huge and deadly Chinese vipers and bamboo vipers, as well as nonpoisonous pythons, which are up to 20 feet long. Insects of every description—crickets, butterflies, dragonflies, grasshoppers, cicadas, and beetles—are found in profusion. Amphibians include ground burrowers and many types of frogs and toads.

Tigers, rhinoceroses, panthers, wolves, bears, and foxes once roamed the hills of Kwangtung, but their numbers have been decimated by forest fires and persistent deforestation; they are now considered to be extinct in the area. In the tropical monsoon forest, however, a great number of animals, many of which live in the trees, still remain.

Settlement patterns. Most of the people of the province live in villages, which remain the basic functional units in the countryside. Population distribution bears almost a one-to-one correlation with agricultural productivity. The greatest numbers of villages are in the fertile river deltas and along the waterways. To an even greater extent, towns and cities are located in the deltas and coastal areas

Urbanization

and along major communication lines. The most highly urbanized area within the province is the Pearl River Delta, where almost two-thirds of the population lives in urban areas. Kwangtung is a relatively highly urbanized province for China, with about half of its population being classified as urban. The urban hierarchy is headed by Canton. Canton and Chan-chiang are designated "open" coastal cities, and Swatow (Shan-t'ou), together with Shenchen and Chu-hai (situated near Hong Kong and Macau, respectively), are special economic zones; all have been central to the province's economic growth.

The people. Kwangtung is populated largely by the Han (Chinese), the other ethnic minorities totaling only a tiny portion of its population. The Yao (Mien) are the largest ethnic minority in Kwangtung and are concentrated principally near its northwestern border in autonomous counties. A heavily Sinicized group, the Chuang, live in Lien-shan, and the She live in the northeast around Ch'ao-an. The Ching were transferred to Kwangsi in 1965, when the multinational Tung-hsing Autonomous County in extreme southwestern Kwangtung changed its provincial jurisdiction. The so-called Tan, or Tanka, the Boat People, are not officially designated as a national minority. They speak Cantonese and generally live along the rivers in the Pearl Basin as well as along the coast.

The relative ethnic homogeneity of Kwangtung contrasts with a great diversity of dialects and languages. Most important is Cantonese, spoken in central and western areas. Once thought to be a dialect of Chinese, it is now considered a language in its own right. There is much variety among the Cantonese speakers, but the form spoken in Canton is generally regarded as the standard. Hakka, another important language, predominates in the north and northeast of the province. Offshoots of Hakka are common in central Kwangtung. A third major language, Min-nan (sometimes considered a south Fukien dialect of Chinese), is spoken mostly in an eastern coastal area centred on Swatow.

In addition to these Sinitic languages, there are the languages and dialects of the ethnic minorities. New scripts have been created for a number of these languages. They not only are taught in minority-area schools but also are used in conjunction with Chinese in official communications in minority communities.

The economy. *Agriculture.* The economic foundation of Kwangtung is primarily agriculture. Rice is the leading crop. Since less than one-fifth of the land is under cultivation, agriculture is of necessity extremely intensive; but the limited extent of sown land available is partly offset by repeated use of it. Progress in irrigation and flood control has made water control possible for almost all of the cultivated area, producing good rice yields. Farming and irrigation have become increasingly mechanized.

Two crops of rice per year can be grown on most cultivated land, and in the Pearl River Delta three crops are not unusual. Thus, although average yields per harvest are below the national average, annual yields exceed the average. Food-grain crops occupy almost all of the total cultivated area, but the industrial and fruit crops grown on the remaining land are of national importance. Kwangtung annually produces much of China's total output of sugarcane. Industrial crops in tropical areas include rubber, sisal, palm oil, hemp, coffee, and black pepper. Among traditional agricultural products are sweet potatoes, peanuts (groundnuts), and tea. Representative fruits grown include citrus, litchi, pineapples, and bananas.

Fishing

Kwangtung, with its long coastline, produces about one-fifth of China's fish. Marine species caught include yellow croaker, white herring, mackerel, golden thread, and pomfret. Fish breeding in ponds or along riverbanks and seacoasts is growing in importance.

Industry. In the first half of the 20th century Kwangtung experienced modern growth as Canton developed into an industrial, commercial, and transportation centre. However, because of the paucity of its iron-ore deposits, the province received only scant attention during the 1950s. The discovery of other mineral deposits prompted the development of some heavier industries, including metal and petrochemical processing, the manufacture of machinery, and shipbuilding and ship repairing. A large proportion of these industries is still concentrated in Canton.

Coal reserves and manganese deposits are located on the Lei-chou Peninsula; quantities of oil-shale deposits have also been discovered there. Tungsten, which is associated with bismuth, molybdenum, and tin deposits, is mined near the Kiangsi border, where uranium is also found. The province also produces some lead and antimony.

Light industry has always been of significance in the province. Apart from handicrafts, light industry—especially food processing and the manufacture of textiles—accounts for about two-thirds of industrial production. Almost all of the major light industries are located in the Pearl River Delta. The largest and most widespread industry is rice milling, which takes place in nearly every county and municipality. Kwangtung's light industrial production has grown dramatically, partly because of the province's level of exports. Kwangtung has been given special authority to develop trade and investment ties with other countries; three of China's first four special economic zones were established in the province.

Transportation. Economically and culturally, the different regions of Kwangtung are linked by the waterways of the Pearl River system. In addition, a number of coastal and international shipping routes are variously linked to more than 100 large and small ports. The leading ports, including Huang-p'u (Canton's seaport), Chan-chiang, and Swatow, are of national significance. Water transport accounts for more than two-fifths of Kwangtung's total traffic tonnage. The waterways are maintained by continually dredging, widening, and clearing channels.

Water transport

Connections with other provinces depend principally on land transportation. Kwangtung has the best highway network in China, which runs primarily along river valleys. Interprovincial links, both for highways and railroads, usually run north-south. Important rail links include the double-tracked Canton–Han-k'ou line, the Canton–Chanchiang line, and the Canton–Swatow line, built in the mid-1990s. The low priority placed on east-west transport is indicated by the absence of a railroad running parallel to the Hsi River.

Kwangtung provides a crucial link in China's domestic and international civil aviation routes. Air services connect the province to numerous international cities. To cope with the increasing traffic, Canton's Pai-yün airport has been enlarged and modernized.

Administration and social conditions. *Government.* The administrative system in Kwangtung has undergone many changes since 1949. Autonomous administrative units were established in the early 1950s for areas with large ethnic minority populations. The status of Canton was changed in 1954 from a centrally administered municipality (*t'eh-pieh-shih*) to a prefecture-level municipality (*ti-chi-shih*) under the jurisdiction of the provincial government. In addition to the municipality of Canton, Kwangtung is subdivided into 20 other prefecture-level municipalities. Kwangtung is further divided into counties (*hsien*), autonomous counties (*tzu-chih-hsien*), and county-level municipalities (*hsien-chi-shi*). Rural administration was reorganized in 1958 when communization replaced the administrative villages, market towns, and municipal districts. In 1980–81 the government implemented a policy of greater decentralized economic management, and the communes lost their administrative role.

Education. Education, health, and other social conditions in Kwangtung have generally been improved since 1949. There are now many more kindergartens and nurseries for preschool education, secondary schools, and post-secondary schools and universities. Repeated campaigns have succeeded in reducing illiteracy throughout the province. Special attention has been given to the education of the ethnic minorities. New schools, including a national minority college, have been established in minority communities.

Health and welfare. In general, hospitals, clinics, and many health stations, including maternity centres, are available at the local level. Better equipped and better staffed hospitals are maintained at the county and provin-

Hospitals, clinics, and medical services

cial levels. Medical education has been greatly expanded and includes a college devoted to Chinese medicine (acupuncture and herbal medicine). Many short-term medical-training classes are organized for health workers assigned to rural areas. The development of medical services, coupled with the general improvement in sanitation and health education, has succeeded in eliminating many previously common diseases such as malaria, schistosomiasis, and filariasis.

Cultural life. Kwangtung has long been noted for the distinctive cultural traits of its people, as evidenced by the variety of dialects spoken. Kwangtung is famous for its two types of local opera: the Yüeh Opera and the Ch'ao Opera, which are popular among the Cantonese and Fukienese communities, respectively. Kwangtung also has some characteristic puppet plays. The hand puppets of Canton are distinguished by their size—they are between three and four feet high—and by the beautiful carving of their wooden heads. Many places in Kwangtung have distinctive forms of folk art; examples are the woodcuts of Ch'ao-an and the stone engravings of Shun-te.

Cantonese food is widely recognized as among the best in China. Living in a coastal province, the people are fond of seafood. Especially in winter, the "big-headed fish" (tench) is often served raw in a salad—a departure from popular Chinese culinary practice. Some other foods, such as newborn rats, monkey's brain, and fried snake, are regarded as revolting by most Chinese in other provinces. Chinese who have returned from Southeast Asia have popularized the chewing of betel nut wrapped in *Celosia* (cockscomb) leaves.

Religions

Ancestor worship, folk religions, and the institutional religions of Taoism, Buddhism, Christianity, and Islām coexist in the province, as they do in most places in China. Among these religions, ancestor worship has the most pervasive influence. Although some folk religions are national in outlook, others are of a more regional or local character, such as the worship of the goddess of fishing and navigation, T'ien-hou Sheng-mu. With the possible exception of Muslims and Christians, people in Kwangtung are polytheistic, visiting temples or priests of different faiths as occasions demand.

Kwangtung is a province where lineage—an important social institution in China—has been emphasized. The importance of ancestry is often reflected in the settlement pattern of lineage groups. The inhabitants of many villages belong exclusively to one or two lineages. In such villages, community and lineage organizations are virtually identical. Conflicts between lineages were once common and often took the form of community strife, with bitter vendettas sometimes lasting for long periods of time.

With the founding of the new regime in 1949, systematic efforts were made to change these cultural patterns in accordance with governmental ideology and policy, although in the early 1980s limited religious practice was again allowed. On the other hand, many aspects of traditional culture, especially the folk arts and the theatre, were revived and extolled.

HISTORY

Physically separated from the early centres of Chinese civilization in North China, Kwangtung was originally occupied by non-Han ethnic groups. It was first incorporated into the Chinese empire in 222 BC, when Shih huang-ti, first emperor of the Ch'in dynasty, conquered the area along the Hsi and Pei river valleys down to the Pearl River Delta. In 111 BC Chinese domination was extended to the whole of what is now Kwangtung, including Hai-nan, by Wu-ti of the Han dynasty. The conquest, however, was not followed by successful colonization, and Kwangtung remained part of the empire only politically.

During the five centuries of the Sui, T'ang, and Pei (Northern) Sung dynasties, from AD 581 to 1127, the military and agricultural colonization of Kwangtung gradually took place. This colonization, combined with increasing overseas trade channeled through Canton, led to an increase of migration into Kwangtung and to the emergence of Canton as a metropolis with a population of hundreds of thousands. At the end of the period, however, Kwangtung was still occupied predominantly by its original ethnic population. The region was viewed as a semicivilized frontier, and disgraced officials often were exiled there.

The southward thrust of the Han was greatly intensified from 1126, when the Juchen of the Chin dynasty captured the Pei Sung capital at what is now K'ai-feng, forcing the Sung to migrate south. Another major population movement followed a century and a half later as China fell to the Mongols. These migrations marked the beginning of effective Han occupation and the rapid cultural development of Kwangtung. Especially after the 16th century the growth of population was so fast that, by the late 17th century, Kwangtung had become an area from which emigration took place. Migrants from Kwangtung moved first to Kwangsi, Szechwan, and Taiwan and then in the mid-19th century began to pour into Southeast Asia and North America, and some were also taken as indentured labourers to British, French, and Dutch colonies.

Occupation by the Han

Since the mid-19th century, Kwangtung has produced a number of prominent political and military, as well as intellectual, leaders. Many of the leaders of political movements during this period—such as Hung Hsiu-ch'uan, leader of the Taiping Rebellion (1850–64); K'ang Yu-wei and Liang Ch'i-ch'ao of the Reform Movement (1898); and Sun Yat-sen, who led the republican revolution of 1911–12—had associations with Kwangtung.

In the 1920s Chiang Kai-shek made Canton the base from which his program to reunify China under Nationalist rule was launched. Foreign privileges in the city were reduced, and modernization of the economy was undertaken. The almost simultaneous rise of the Communist movement and the advent of Japanese aggression in the 1930s, however, thwarted the plans of Chiang and the Nationalists. From 1939 to 1945 the Japanese occupied Kwangtung Province. After World War II the conflict between the Communists and the Nationalists erupted into full-scale civil war and continued until the Communist victory in late 1949. (Y.-m.Y./C.-t.C./V.C.F.)

Kweichow

Located in the southwestern part of China, the province of Kweichow (Kuei-chou in Wade-Giles romanization, Guizhou in Pinyin) is bounded to the north by Szechwan Province and Chungking Municipality, to the east by Hunan Province, to the south by the Chuang Autonomous Region of Kwangsi, and to the west by Yunnan Province. Kweichow measures more than 350 miles (560 kilometres) from east to west and about 320 miles from north to south. It has an area of 67,200 square miles (174,000 square kilometres). The provincial capital is Kuei-yang.

Kweichow has the frontier character of other southwestern plateau lands: rough topography, difficult communication and isolation, and many ethnic minority groups. It has long been considered one of China's poorest and most disadvantaged provinces, as characterized by a folk poem:

"The sky is not three days clear; the land is not level for three *li* (2,115 feet, or 645 metres); the people don't have three cents."

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Kweichow Province is part of an old eroded plateau, variously known as the Kweichow Plateau or Yunkwei Plateau, which connects with plateau areas in Yunnan Province. Situated between the Plateau of Tibet and the hilly regions of Hunan and Kwangsi, the plateau forms part of a continuously ascending profile of the southwest, its altitude increasing from about 2,300 feet in eastern Kweichow to about 6,600 feet in the west. The Szechwan Basin to the north and the Kwangsi Basin to the south are both the results of faulting. The entire terrain of Kweichow thus slopes at a steep angle from the centre toward the north, east, and south. In areas adjacent to Szechwan and Hunan in the north and east, the elevation is about 2,300 feet, while the province's southern slopes descend 1,600–2,000 feet into Kwangsi. Accordingly, rivers in the province flow in three directions, north, east, and south.

The plateau, which is mostly of limestone and basalt, has undergone complicated and extensive folding, faulting, and stream erosion and consequently has abrupt relief, an example of which is the famous Huang-kuo-shu Waterfall near An-shun in the southwest. Incised valleys, steep gorges, and cliffs are very common. In the limestone areas the landscape is karstic (characterized by precipitous slopes, abrupt, protuberant mountains, caverns, and subterranean streams). Only the anticline (upfold of stratified rock) and syncline (downfold of stratified rock) of the plateau in central Kweichow are broad and relatively flat.

Karstic features of the landscape

Drainage and soils. Most of the rivers in Kweichow are the upper streams of large rivers, such as the Yangtze and the Hsi. The abrupt change of gradient, the great fluctuation in the flow volumes, and the many rapids and reefs make them unsuitable for navigation, though they have enormous hydroelectric power potential.

Because of the high humidity, a yellow soil with a yellowish-brown subsoil originated from sandstone, shale, and clay constitutes the largest area in the province. In the limestone area in the south there are broad areas of red soil. In the west the red soils are originated from basalt and sandstone and developed under a relatively drier climate.

Climate. Kweichow enjoys a mild climate with warm summers and mild winters. Kuei-yang has a mean July temperature of about 76° F (24° C), lower than that of all other cities to the east on the same latitude. This is due to its high altitude and the cloudiness of the summer months. In winter, cold air from Siberia cannot easily reach Kweichow because of the barrier effect of the Tsinling Mountains to the north of the Szechwan Basin. In spite of its high altitude, Kweichow thus has few snowy days and even fewer freezing days. The mean January temperature at Kuei-yang is about 41° F (5° C).

Rainfall is fairly uniform and plentiful, with an annual average of 31–51 inches (787–1,295 millimetres), decreasing toward the north and west. The southern and eastern parts of Kweichow are open to the influence of the moist maritime air mass in summer. For the same reason, there is a summer maximum in rainfall, averaging 45 percent of the annual total. About 25 percent falls in spring and 23 percent in autumn. Typically, the province has high relative humidity, lengthy cloudy and rainy days, and little sunshine. The capital, Kuei-yang, has more than 260 rainy and cloudy days in an average year. Most of the precipitation results from frontal activity, though some is a result of convection or condensation.

Plant and animal life. Because of the steep gradient and the exposure of limestone, wasteland accounts for nearly half of the total area. Yet part of the province's natural wealth lies in its forests. The plateau surface is mostly dry and barren, but the peripheral valleys have rich and valuable woodlands. There are four main forested areas: the drainage areas of the Ch'ing-shui River in the east, the Jung River in the southeast, the Nan-p'an and Pei-p'an rivers in the southwest, and the Ta-lou Mountains in the north.

Forest resources

The forests of the northern valleys, still among the most important in China, consist chiefly of conifers and other trees, such as the tung tree, lacquer tree, camellia, birch, maple, pine, and fir. Forests in the southeast produce camphor, banyan tree, and other broad-leaved varieties. Trees of the southern subtropical valleys typically include willow, cedar, bamboo, and various species of pine and fir. Oak, Yunnan pine, *Hua-shan* pine, and camphor are grown in the west near Yunnan. Cedar, cypress, poplar, and palm trees are also found in the province.

In addition to domesticated animals, such as buffalo, horses, donkeys, asses, and pigs, the province's fauna includes leopards, otters, foxes, badgers, tigers, and squirrels. In most of the larger rivers carp and savoury fish are abundant.

The people. About three-fourths of the province's population is Han (Chinese). Members of the more than 30 non-Han ethnic minority groups account for the remainder. Among the most important minority groups are the Miao (Hmong), the Puyi, the Yi, the Tung, the Shui, the Yao (Mien), and the Chuang. All of the minority groups intermingle with Han people. Only at the low *hsiang*, or village, level can one find any exclusive ethnic grouping. Generally, few minority people live in northern Kweichow, particularly in areas north of the Wu River. The Miao are mainly found in southeastern Kweichow, especially in the drainage area of Ch'ing-shui River and in the Miao Mountains. Most of the Puyi live in south-central and southwestern Kweichow in the P'an River drainage area, including the suburbs of Kuei-yang. The Tung are found mainly in the southeastern areas adjacent to Hunan and the Chuang Autonomous Region of Kwangsi. The Shui concentrate in southern Kweichow, around San-tu and Li-po, while the Yi, who once were rulers of this frontier region, are scattered in western Kweichow. The Hui (Chinese Muslims) in Kweichow migrated there from Yunnan in the late Ch'ing dynasty after the defeat of a local rebellion. They are found chiefly in towns and cities along the main lines of communication in western and southern Kweichow, especially in Wei-ning.

Main ethnic groups

Most of the population is rural, and agriculture is the chief occupation. Rice cultivators dominate the peripheral valleys of the plateau. On the plateau itself, the Miao practice a more primitive form of agriculture, growing subsistence upland crops. Most of the Puyi live on level lands in the valleys and cultivate rice. While the Tung are experienced lowland rice cultivators, they are also skillful in forestry and in growing upland crops. The Shui, living together in large families and tribes, are rice cultivators as well. In addition to growing upland crops, the Yi undertake animal husbandry.

There are few cities in Kweichow. Kuei-yang is the most important, although larger and more populous is Liu-p'an-shui, a municipality created by combining the Liu-chih, Pan-hsien, and Shui-ch'eng special districts in Kweichow's coal-rich west. Most of the other cities are the seats of government and are the economic and communications centres for the various regions of the province.

Chinese is the common language of the Han and the Hui in Kweichow, Mandarin being spoken almost exclusively by the former group. Among other minority peoples, only the Miao, Chuang, Yi, and Puyi have their own languages. The languages of the Puyi, Shui, Tung, and Chuang are Tai languages. Those of the Miao and the Yao belong to the Miao-Yao group, and that of the Yi to the Tibeto-Burman group.

The economy. *Resources.* Kweichow has rich mineral resources. Its most widespread metallic mineral is mercury, reserves of which are large; there are also small deposits of manganese, zinc, lead, antimony, aluminum, copper, iron, and gold. Its most nonmetallic minerals include coal, petroleum, oil shale, phosphate, gypsum, arsenic, limestone, and fluorite. Extractive industries are consequently very important in Kweichow.

Agriculture. Most of the cultivated area of Kweichow is under grain crops, the most important of which is rice. Corn (maize) is grown chiefly in eastern Kweichow. Other food crops include wheat, barley, sweet potatoes, potatoes, oats, and broad beans. Increasingly more of the cultivated

Main food crops

area is under industrial crops, of which the most important is rapeseed, followed by tobacco, peanuts (groundnuts), sugarcane, jute, tea, sugar beets, hemp, and sesame. Kweichow is also known for its production of *mao-tai* liquor, made from wheat and kaoliang.

Timber and other forestry products are plentiful. Kweichow ranks among the leading provinces in the production of raw lacquer and tung oil. Other important forestry products include camellia oil, cypress oil, gallnut extract, lichens, and various medicinal herbs.

Industry. Kweichow's iron and steel industry is based on the local supply of raw material and fuel and an expanding market in southwestern China; machinery manufacturing has also been established, primarily for the production of mining machinery, agricultural and irrigation equipment, steel-rolling machines, and steel-smelting and other smelting equipment. With its abundant water resources, the province has developed numerous small hydroelectric facilities. The local supply of phosphate and other raw materials has given rise to a chemical industry that produces fertilizers, soda acid, and other chemicals and petrochemicals. The textile industry has grown significantly, and paper mills are found in several cities. Tourism is growing in importance, visitors being drawn to the province's many scenic spots.

Kuei-yang is the most important industrial centre of the province, producing a wide variety of heavy and light industrial goods. Other major centres include Tsun-i, which has a considerable amount of heavy industry and is also the focus of silk textile production, and the municipality of Liu-p'an-shui, with its coal-based extractive and other heavy industries.

Transportation. River transportation is of little importance in Kweichow due to the presence of reefs and rapids, although the Wu River is a prosperous waterway. Several of the province's other rivers are partially navigable. Kweichow's highways are relatively well-developed. Since 1958 all counties have been connected by roads, the majority of which have all-weather surfaces. Prior to the completion of the railway from Kweichow to Kwangsi in 1959, the Kweichow–Kwangsi highway was the principal freight and passenger route to Kwangtung and Kwangsi and to central and east China. Since then, railway lines have been extended to Yunnan, Szechwan, and Hunan.

Administration and social conditions. *Government.* Administratively, Kweichow is divided into three prefecture-level municipalities (*ti-chi-shih*), three prefectures (*t'i-ch'ü*), and three autonomous prefectures (*tzu-chih-chou*). These are further divided into counties (*hsien*), autonomous counties (*tzu-chih-hsien*), and county-level municipalities (*hsien-chi-shih*).

Kweichow was in turmoil during the most violent phase (1967–69) of the Cultural Revolution. Although Revolutionary Committees were established in most major cities, local military units maintained order and stability. In May 1971 the Kweichow Provincial Party Committee was reestablished, and in 1980–81 the Revolutionary Committees were abolished and replaced with People's Governments and People's Congresses.

Education. Kweichow has one of the highest rates of illiteracy in China, especially among its many minority peoples. Nonetheless, there are a number of institutions of higher learning in the province, including Kweichow University, Kuei-yang Medical College, Kweichow University of Technology, the Kuei-yang Nationalities College (for training members of ethnic minority groups), and Kuei-yang Chinese Medical College. The province also has some 200 natural science institutes.

Health and welfare. Since 1949 great strides have been made in public health, although Kweichow lags behind most of the rest of China in such areas as life expectancy and the eradication of endemic diseases. Several hundred health stations, mother-and-child-care centres, and maternity centres have been established. Health-work teams have also been established, and larger numbers of medical personnel have been trained and organized.

Cultural life. The minority peoples in Kweichow are among the most artistic and musical in China. The Han also have a long and mixed cultural background. Various types of folk dramas with varying degrees of elaboration, some of which are combined with folk dances, are popular among different nationalities in different areas. Some of the Han folk dramas, *hua teng* ("flower lantern") in northern Kweichow and *ti-hsi* ("floor plays") in southern Kweichow, are also popular among the minority groups. Buffalo fighting is part of the festival activity over the New Year, especially among the Miao, Yao, and Chuang peoples. The Miao often sing of their revolutionary history and heroes, and both the Miao and the Tung folk songs are well known. Embroidery and paper cutting are both important forms of folk art among all minority peoples. The Puyi and Ch'i-lao are particularly known for their batik, the Miao and Puyi for their intricate, coloured cross-stitch work, and the Miao for their heavy silver ornaments.

Folk dramas and dances

HISTORY

Although the area has been known to the Chinese since time immemorial, Kweichow came under large-scale Chinese influence only since about the period of the Ming dynasty (1368–1644), when it was made a province. The colonization policy of the Ming and Ch'ing dynasties encouraged a large number of Chinese immigrants from Hunan, Kiangsi, and Szechwan to move into the eastern, northern, and central parts of Kweichow.

Kweichow's history of rebellion

Minority groups, particularly the Miao, rebelled during the Ch'ing dynasty (1644–1911/12), when the government decided to replace local chiefs by officials appointed by the central government. Rebellions and suppressions were so common that there was a saying, "a riot every 30 years and a major rebellion every 60 years." In 1726 at the Battle of Mount Lei-kung, more than 10,000 Miao were beheaded and more than 400,000 starved to death. The Pan-chiang Riot of 1797 was said to have been started by the Puyi people, and thousands of them were either burned to death or beheaded. The most important popular revolt against the central government was one led by Chang Hsiu-mei, a Miao, in 1854. He and his followers united with the Taiping revolutionaries, and the joint army with a centralized command that was organized soon controlled eastern and southern Kweichow and won numerous victories under the Miao leaders Yen Ta-wu and Pa Ta-tu. When the Miao were eventually defeated in 1871, however, countless numbers of them were massacred. Another revolt, known as the Ch'ien Tung (eastern Kweichow) Incident, occurred between 1941 and 1944 as a result of exploitation and suppression by the warlord Wu T'ing-chang. Bitter struggles between the Miao and Wu's armies went on until 1944.

(C.-K.L./R.L.Su.)

Szechwan

Szechwan (Ssu-ch'uan in Wade–Giles romanization, Sichuan in Pinyin) is the second largest province of China, both in terms of area and population. Located in the Upper Yangtze Valley in the southwestern part of the country, it covers an area of 210,800 square miles (546,000 square kilometres). Szechwan is bordered by Kansu and Shensi provinces to the north, Hupeh and Hunan provinces and Chungking Municipality to the east, Kweichow and Yunnan provinces to the south, the Tibet Autonomous Region to the west, and Tsinghai Province to the northwest. The name Szechwan means "Four Streams" and refers to the four main tributaries of the Yangtze River, which flows through the province. The capital is Ch'eng-tu. Szechwan was long the most populous province in China until Chungking Municipality was formed out of its eastern portion in 1997.

From economic, political, geographical, and historical points of view, the heart and nerve centre of Szechwan is in the eastern basin area, commonly known as the Szechwan, or Red, Basin. Its mild and humid climate, fertile soil, and abundant mineral and forestry resources make it one of the most prosperous and economically self-sufficient regions of China. The area has been seen by some as China in a microcosm and is often viewed as a country within a country. The Chinese call the basin Tien Fu Chih Kuo, which literally means "Heaven on Earth."

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Szechwan is bordered on all sides by lofty highlands. To the north, the Tsinling Mountains extend from east to west and attain an elevation between 11,000 and 13,000 feet (3,300 and 4,000 metres) above sea level. The limestone Ta-pa Mountains rise to approximately 9,000 feet on the northeast, while the Ta-lou Mountains, a lower and less continuous range, with an average elevation of 5,000 to 7,000 feet, border the south. To the west, the Ta-hsüeh Mountains of the Tibetan borderland—rise to an average elevation of 14,500 feet; to the east, the rugged Wu Mountains, rising to about 6,500 feet, contain the spectacular Yangtze Gorges.

Szechwan Basin

In general, the relief of the eastern region of the province is in sharp contrast to that of the west. The extensive Szechwan Basin and its peripheral highlands predominate in the east; the land slopes toward the centre of the basin from all directions. This basin was a gulf of the China Sea in the later Paleozoic Era from 570,000,000 to 225,000,000 years ago; most of it is underlain by soft sandstones and shales that range in colour from red to purple.

Within the basin, the surface is extremely uneven and gives a general appearance of badland topography. Numerous low, isolated, and rolling hills are interspersed with well-defined high ridges, floodplains, valley flats, and small, local basins. The most impressive portion of the basin's surface is the Ch'eng-tu Plain—the only large continuous tract of relatively flat land in the province.

The landforms of western Szechwan include a plateau in the north and mountains in the south. The northern area is part of the edge of the Plateau of Tibet, which consists of highlands above 12,000 feet and higher mountain ranges. There is also an extensive plateau and some swampland. To the south the transverse mountain belt of eastern Tibet and western Yunnan Province rises to an average of between 9,000 and 10,000 feet. Trending from north to south is a series of parallel lofty ranges with narrow divides and canyons more than a mile deep. Mount Kung-k'a (Minya Konka) in the Ta-hsüeh range, is the highest peak in the province, rising to a height of 24,790 feet.

Drainage. Seen from the air, the principal drainage pattern of the eastern section of the province has the appearance of a leaf with a network of veins. The Yangtze—flowing from west to east—is conspicuous as its midrib, and the main north and south tributaries appear as its branch veins. Especially important are the Chia-ling and Min river systems in the north. The distribution of these veins is primarily concentrated in the upper, or northern, half of the leaf.

The four main tributaries of the Yangtze, to which the name Szechwan refers, are the Min, T'o, Chia-ling, and Fou rivers, which flow from north to south. Most of the major streams flow to the south, cutting steep gorges in the west or widening their valley floors in the soft sediments of the Szechwan Basin; they then empty into the Yangtze before it slices its precipitous gorge beginning to the east in Chungking Municipality. Within the basin most of the rivers are navigable and are heavily used.

Soils. There are six major soil regions—three in the east and three in the west. In the east, they include the highly fertile, purple-brown forest soils for which the Red Basin is named. This group of soils rapidly absorbs and loses water, so that it erodes easily. The other eastern soils consist of the noncalcareous alluvium and rice-paddy soils of the Ch'eng-tu Plain and other river valleys and the yellow earths of the highlands and ridges. The alluvial soils are the most important group agriculturally, as they are very fertile and are formed mainly from the rich black soils washed down from the Tibetan borderlands. The yellow earths are usually gray-brown in colour, are generally less fertile, and are agriculturally unimportant. The three major groups of soils in the west are the degenerated chernozem (dark-coloured soils containing deep, rich humus) soils of the Sung-p'an grassland, the alluvial soils of the numerous valleys, and the podzolized (leached), gray-brown soils of the mountain slopes.

The problem of soil creep

In Szechwan a form of soil erosion known as soil creep has developed. On hillsides where the surface slopes are composed of smooth sandstones, the covering soil gradually slides downward under the influence of gravity. In many places the thin surface soils have been completely removed, leaving only bare rocks. When the surface rock is composed of comparatively rougher shales, the soil is less easily moved.

Climate. The eastern basin area and the lower western valleys are sheltered from cold polar air masses by the surrounding mountains. The climate is therefore milder than would be expected and is similar to that of the Yangtze Delta region. There are more than 300 frost-free days in the eastern basin, and the growing season lasts nearly all year round. In the west, the sheltering effect of the mountains is evident from the contrast between the perennially snow-capped peaks and the mild weather prevailing in the valleys beneath them. During the summer, in the month of July, the mean temperature is about 84° F (29° C) in the southeast and less than 68° F (20° C) in most parts of the west. During the winter the mean temperature in the west decreases northward from 54° F (12° C) in Hsi-ch'ang to 18° F (−8° C) in Ch'ien-ning.

The eastern rainy season begins in April and reaches its peak during July and August. Annual rainfall and precipitation measures about 40 inches (1,000 millimetres) annually. The east is noted for its frequent fogs, its many cloudy days, the relative absence of wind, and the high relative humidity. The extent to which the region is overcast is reflected in the saying, "Szechwan dogs bark when they see the Sun." Precipitation is lower in the west than in the east. The average total of about 20 inches falls mainly during the summer and early autumn, and there is heavy snowfall in the mountains during the winter.

Vegetation regions

Plant and animal life. There are four major vegetation regions—the pine-cypress-banyan-bamboo association of the basin area, the dense mixed association of coniferous and deciduous trees in the eastern highlands, the grasslands of the northwest, and the dense coniferous forests of the western highlands. Its great altitudinal differences, low latitudinal position, diversified topography, and high rainfall make the area what has been called a paradise for botanists. Extensive forests grow on the upper slopes, and rich rhododendrons are found at higher elevations; arid vegetation prevails on many canyon floors.

One of the outstanding features of vegetation of Szechwan Province is its division into vertically differentiated zones. Cypress, palm, pine, bamboo, tung, and citrus fruit trees grow below 2,000 feet, while between 2,000 and 5,000 feet there are evergreen forests and oaks. From 5,000 to 8,000 feet the vegetation is characterized by dense groves of mixed coniferous trees. Between 8,500 and 11,500 feet there is a subalpine zone of coniferous forest, while above 11,500 feet

there are alpine zones of scrub and meadow up to the snow line, which occurs at 16,000 feet. One of the unique vegetational features is the presence of the dawn redwood, or *Metasequoia*—a tree previously believed to be extinct.

Two of the most interesting indigenous animal species are the *hsiung-mao* (lesser panda, or bear cat) and the *ling yang* (a species of antelope). Both inhabit the highlands of western Szechwan, and both have become endangered because of habitat destruction.

Settlement patterns. As one of the most densely populated provinces of China, Szechwan may be compared to the Yangtze Delta and the North China Plain. The population, however, is unevenly distributed, with most of the population concentrated in the eastern part of the province. The majority of the population is rural. There are comparatively few large villages and nucleated hamlets, except for the provincial and prefectural capitals. In the hilly regions, farmsteads are scattered through generally small and irregular terraced fields. In the Ch'eng-tu Plain the larger field units are commonly square or oblong in shape, and the farmsteads are surrounded by groves of banyan, cypress, mimosa, palm, or bamboo.

Most urban settlements give the appearance of being compactly built. Generally, the houses have only one story. There are no yards or sidewalks in front of the houses, which abut streets that are narrow and often are paved with limestone slabs. One of the outstanding features of urban settlement is the concentration of cities on river terraces, notably along the Yangtze River. Because water transportation is vital, large cities are always found wherever two major streams converge. Examples of such cities include Lu-chou on the Yangtze and the T'o rivers and Lo-shan on the Ta-tu and the Min. The principal disadvantage of these urban sites is that their areas are limited by their locations, so that development is hindered; the hazards of flooding are always a problem. Ch'eng-tu, the provincial capital and Szechwan's largest city, is located in the centre of the Ch'eng-tu Plain.

The relation between cities and rivers

The people. Szechwan Province has one of the most diversified ranges of ethnic groups in all China, including Han (Chinese), Yi, Tibetans, Miao, T'u-chia, Hui (Chinese Muslims), and Ch'iang peoples. Most of the Han—who comprise the major part of the population—live in the basin region of the east. The Yi reside in the Liang-shan-i-tsu Autonomous Prefecture of the southwest, while the Tibetans are distributed in the plateau region of the west. The Miao live in the mountains of the southwest near Kweichow and Yunnan provinces. The Hui are concentrated in the Sung-p'an grassland of the northwest and are also scattered in a number of districts in the east. The Ch'iang are concentrated in the Mao-wen area on both banks of the Min River.

Minority peoples

The majority of the non-Han ethnic groups are fiercely independent and have maintained their traditional way of life. In most cases, they practice a mixture of agriculture, animal husbandry, and hunting. Among the Han there has been an influx of people from various neighbouring provinces, particularly from Hupeh and Shensi. This immigration was especially intensified in the early part of the 18th century, as a result of the massacre of the people of Szechwan by a local warlord. The immigrants brought with them agricultural techniques that are reflected in the heterogeneity of present cultivation patterns.

There are three major linguistic groups: the Han, who speak Southern Mandarin; the Tibeto-Burman group, including the Tibetans and the Yi; and the Hui, who speak Southern Mandarin but use Turkish or Arabic in their religious services. The Han practice a mixture of Confucianism, Buddhism, and Taoism. They do not maintain rigid boundaries in religious belief. The Tibetans follow their own form of Buddhism. Many people in the northwest profess Islām, while some hill tribes of the southwest may be classified as animistic.

The economy. The loss of Chungking's considerable economic resources in 1997 was a blow to Szechwan's economy. Nonetheless, Szechwan—with a varied mix of agriculture, forestry, mining, and diversified industry—has one of the strongest provincial economies in the country. It occupies an important position along the upper reaches of the Yangtze, and the Szechwan Basin is well-endowed with natural resources and a large workforce.

Resources. Mineral deposits are abundant and varied. They include both metallic and nonmetallic deposits, such as iron, copper, aluminum, platinum, nickel, cobalt, lead and zinc, salt, coal, petroleum, antimony, phosphorus, asbestos, and marble. The production of brine salt is the most extensive mining activity. Petroleum and natural gas are often located together and are widely spread throughout the province, especially in the Tzu-kung area. Natural gas has been used for centuries in the production of brine salt. Most coalfields are located in the eastern and southern mountain areas. The most important iron deposits are along the southern and western plateau areas; those of the western sector are of high-quality titaniferous magnetite associated with vanadium. Some placer gold is panned along the Chin-sha ("Gold Sand") River. Other valuable minerals include tin and sulfur.

Agriculture. Most of the population of the province earn their livelihood from agriculture, and most of the provincial exports are agricultural products. Cultivation is characterized by the diversity of crops, intensive land use, the extensive practice of terracing, irrigation, the cultivation of *tsai-sheng-tao* (or "rebirth" rice), and the special methods of soil culture, fertilization, composting, and crop rotation.

Agricultural practices

The basin area of eastern Szechwan is extensively terraced and is often known as a "land of 1,000,000 steps." The terraces are of varying dimensions, commonly long narrow strips of land that frequently have rather steep slopes. They are easy to construct because the bedrock is soft and weathers easily. Even 45-degree slopes have tiny steps of terraced land. Irrigation is widely practiced in the terraced fields, and numerous methods and devices are employed. Among the most spectacular is the Tu Chiang-yen system of the Ch'eng-tu Plain, which captures the torrential flow of the Min River and guides it through an artificial multiplication of channels into numerous distributaries along the gently graded plain. Annual dredging keeps the river level constant. The system is not only the oldest but also the most successful and easily maintained irrigation system in China. It has freed the plain from the hazard of floods and droughts and ensured the agricultural prosperity of the basin. A special landscape feature of the eastern basin is the *tung-shui-t'ien* (literally "winter water-storage field") system, in which large tracts of terraced fields are left fallow during the winter season and are used for the storage of water that is needed in the paddy fields in the spring; from the air they resemble a mosaic of broken mirrors.

Tu Chiang-yen irrigation system

Crops range from those of subtropical climates to those of the cool temperate zone. Although Szechwan is generally classified as a rice region, it is also a leading producer of such crops as corn (maize), sweet potatoes, wheat, rapeseed, kaoliang (a variety of grain sorghum), barley, soybeans, millet, and hemp and other fibre crops. Tropical

fruits—such as litchi and citrus—grow together with the apples and pears of cool temperate climates. Other principal cash crops include sugarcane, peanuts (groundnuts), cotton, tobacco, silkworm cocoons, and tea.

Szechwan leads the nation in the total number of its cattle and pigs. It is the only region in China in which both water buffalo of South China and oxen of North China are found together. Pig bristles from Szechwan have been an important item of foreign trade for years. About half of the inhabitants of the west are pastoral. Their animals include cattle, sheep, horses, donkeys, and yaks.

Forestry. Szechwan is second only to China's Northeast as a lumber region. Valuable forests are located on the peripheral highlands that surround the basin area and on the numerous hills within the basin. Western Szechwan still has much of its original forest cover. The most important products from the forests are tung oil, white wax, and various kinds of herbs.

Industry. Szechwan has undergone considerable industrial development since the 1950s, and it has become the most industrialized province of southwestern China. The most important industries include iron and copper smelting, the production of machinery and electric power, coal mining, petroleum refining, and the manufacture and processing of chemicals, textiles, and food. Ch'eng-tu is the principal industrial centre; other large industrial cities in the province include Le-shan, Mien-yang, P'an-chih-hua, and Te-yang. Szechwan is also known for its cottage industries; it has a long history of silk production. Other products include handwoven cloth, embroidery, porcelain, carved stone, and silver and copper items. Tourism is increasingly important, notably at Mount E-mei and its Le-shan Giant Buddha.

Transportation. Among the problems facing the province, none is more important and more acute than that of transportation. For centuries, travel into or out of the province has been extremely difficult; the main entrances to it were the dangerous Yangtze Gorges to the east of Chungking, a treacherous plank road across the mountains in the north, and the deep canyons and swift currents of the Ta-tu and Chin-sha rivers in the west. Since the 1950s great efforts have been made to improve transportation. The Yangtze has been made navigable, railways have been built across the northern mountains, and steel bridges have been constructed over rivers in the west.

Water routes are the most important means of transportation. Of the approximately 300 streams in the province, the Yangtze River is the most significant, traversing the entire width of the basin from the southwest to the northeast. It is the spinal cord of the river transportation system. In the west, water transport is difficult and limited except for the lower reaches of the An-ning and Ta-tu rivers.

Railways are important for the transport of bulky products. Since the 1950s railway construction has included the Ch'eng-tu–Pao-chi railroad—the first to cross the Tsinling range—which connects with the principal east–west Lung-hai Railway and thus links Szechwan to both northwest and coastal China; and the Ch'eng-tu–Chungking railroad, which links the Ch'eng-tu Plain with the Yangtze River. To the south, railways connect Szechwan with Yunnan and Kewichou.

The deeply dissected terrain and the easily weathered rock structures of the province have made the construction and maintenance of highways costly and hazardous because of the constant threat of landslides, the presence of numerous steep slopes and hairpin turns, and the need to construct many solid embankments. Ch'eng-tu is the principal highway centre. Major highway routes connect with bordering provinces in the north, Hupeh in the east, Kweichow and Yunnan in the south, and Tibet in the west. Express highways linking Ch'eng-tu with Chungking and other cities now play an important role in the province's daily traffic.

Principal highways

The province's first commercial air service began in 1937. Since then, commercial flying has grown steadily. Ch'eng-tu is the principal air transportation centre.

Administration and social conditions. *Government.* In 1955, former Sikang Province at the edge of the Plateau of Tibet was incorporated into Szechwan Province, doubling its area. In 1997, the eastern part of the province, with Chungking at its centre, was upgraded to become the country's fourth province-level municipality administered directly by the central government. The province is now divided into 18 prefecture-level municipalities (*ti-chi-shih*) and three autonomous prefectures (*tzu-chih-chou*) and is further divided into counties (*hsien*), autonomous counties (*tzu-chih-hsien*), and county-level municipalities (*hsien-chi-shih*). They are the most important administrative units because it is through them that the government exercises control.

Administrative subdivision

The autonomous prefectures are the A-pa Tibetan Autonomous Prefecture, with its headquarters at Ma-erh-k'ang; the Kan-tzu Tibetan Autonomous Prefecture, with its capital at K'ang-ting; and the Liang-shan-i-tsu Autonomous Prefecture, with its capital at Hsi-ch'ang. As a rule, the autonomous prefectures represent little more than a symbolic cultural indulgence of local minorities. The actual control of the units is exercised by the central government at Ch'eng-tu. The ethnic groups, however, enjoy their own mode of life and preserve their language and cultural traditions with a minimum of interference by the Han-controlled provincial government.

Szechwan Province was a leader in the economic reform movement that began in the late 1970s, introducing innovative policies such as the one that linked farmers' incomes to actual output. Three counties in the province became the first areas to dissolve communes, a practice that soon spread nationwide.

Education. Szechwan has many research centres and institutions of higher education, some of which are "key" schools for training China's most talented students. These are Szechwan University (created from the merger of the university with Ch'eng-tu University of Science and Technology and the West China University of Medical Science), the University of Electronic Science and Technology of China, and the Southwest China Chiao-t'ung University.

Health and welfare. The warm and wet climate of most of the province makes respiratory ailments a major health problem. Because of the severe pressure of the people on the land, the farmers of Szechwan must work extremely hard to eke out a living. The farmers of the Ch'eng-tu Plain are the most prosperous and have the highest standard of living. Rural life is harder in the hills surrounding the basin, and the standard of living is considerably lower in the west, where pastoral activities predominate. In the western mountains, many of the people migrate seasonally from the lowlands to the highlands in search of pasturage.

Cultural life. Ch'eng-tu has always played a vital role in the cultural and intellectual life of Szechwan. The city is a haven for intellectuals and scholars, and—with its heavy traffic, rich nightlife, and luxurious surroundings—is sometimes called the "Little Paris" of China.

Architecture

The unique form of architecture of the eastern basin is characterized by projecting eaves, gracefully curved roofs, and rich, elaborate roof ornaments. Because there is little wind and practically no snow in the basin, these fragile and extraordinarily beautiful structures and decorations can safely be constructed. The frequent misty rains make it necessary to project the roof eaves over the walls to protect them from the rain.

HISTORY

Apart from the Upper Huang Ho (Yellow River) Valley provinces, Szechwan was the first area of China to be settled by the Han. The first organized Han migration took place in the 5th century BC. Szechwan was known as the Shu Pa territory during the Chou dynasty (1111–255 BC). During the Ch'in dynasty (221–206 BC) the territory was incorporated within the Ch'in Empire and began to assume considerable importance in China's national life. It was at this time that the Tu Chiang-yen irrigation system was built. In the time of the San-kuo (Three Kingdoms; AD 220–280) the Szechwan region constituted the Shu kingdom. From the end of this period until the 10th century, Szechwan was known by various names and administered through various political subdivisions. During the Sung dynasty (AD 960–1279) it was known as Szechwan Lu (Szechwan Province). Szechwan was established as a province during the Ch'ing, or Manchu, dynasty (1644–1911/12).

During the early years of the Chinese republic (1911–

30) Szechwan suffered seriously from the feudal warlord system; at one time it was divided into as many as 17 independent military units, and not until 1935 was it unified under the Nationalist government. During the Sino-Japanese War of 1937–45 there was a great influx of people and new ideas from coastal China, which resulted in extensive economic development. Many factories and trading posts were moved from the coastal area into Szechwan, and a number of industrial centres were established, especially in Chungking and at Ch'eng-tu.

Because of its geographic isolation, inaccessibility, extensive area, large population, and virtual economic self-sufficiency, Szechwan has served periodically as a bastion in its own right. The area is easily defensible, and geography has encouraged political separatism. During the war with Japan, the province was the seat of the Nationalist government from 1938 to 1945; the Japanese were never able to penetrate the area. (C.Hu./Y.-G.G.H./R.L.Su./Ed.)

Yunnan

Yunnan (Yün-nan in Wade–Giles romanization, Yunnan in Pinyin), the fourth largest province of China, is a mountain and plateau region on China's southwestern frontier. It is bounded by the Tibet Autonomous Region on the northwest, Szechwan on the north, and the Chuang Autonomous Region of Kwangsi and Kweichow Province on the east. To the south and southeast it adjoins Laos and Vietnam, and to the west it borders Burma for 600 miles (950 kilometres). The area of Yunnan is 152,100 square miles (394,000 square kilometres). The provincial capital is K'un-ming.

The name Yunnan has been in use since the region was made a province under the Yüan (Mongol) dynasty (1206–1368). Literally meaning "Cloudy South," it denotes the location as south of the Yün-ling ("Cloudy Mountain") Range. Although richly endowed with natural resources, Yunnan remained an underdeveloped region until recent times; and for centuries the ethnic, religious, and political separatism of the province posed obstacles to the efforts of a central government to control it. Although the province remains relatively underdeveloped and isolated, its economic, political, and cultural integration into the Chinese nation essentially is complete.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Yunnan's topography is determined by a series of high mountain chains that, starting close together from the Tibetan border, branch out southeastward across the province in fanlike fashion. Running roughly northwest to southeast, these high ranges are, from west to east, the Kao-li-kung, the Nu, and the Yün-ling. Branching farther out from the Yün-ling are some secondary ranges—the Wu-liang and the Ai-lao in the central south area, the Liu-chao in the southeast, and the Wu-meng in the northeast.

The canyon and plateau regions

The province consists of two distinct regions separated by the Ai-lao Mountains—the canyon region to the west of it and the plateau region to the east. In the canyon region the great mountains descend from an altitude of more than 18,000 feet (5,500 metres) above sea level in the north to 6,000 feet in the south. Flowing through the deep, V-shaped valleys between these mountains are the major rivers of the province: the Salween (Nu), flowing between the Kao-li-kung and Nu mountains; the Mekong (Lan-ts'ang), between the Nu and Yün-ling ranges; and the Black (Li-hsien), between the Wu-liang and Ai-lao mountains. The towering height of the mountains in the north is such that valley floors lie at heights averaging 4,000 to 5,000 feet below the mountaintops. The river currents, too swift for navigation, represent an enormous potential for hydroelectric power. In the southern part of the canyon region the mountains are much lower and the valleys more open, with many upland plains and fertile irrigated fields.

The eastern plateau region, stretching from the Ai-lao Mountains to the Kweichow–Kwangsi border, is separated from Szechwan by the Chin-sha (Yangtze) River. Streams on the western fringe of the plateau drain into the Red (Yüan) River, which flows along the eastern slope of the Ai-lao Mountains to enter the Gulf of Tonkin via Vietnam. The water of the central and eastern parts of the plateau drains into the Nan-p'an River, which is a headstream of the Hsi River of Kwangsi and Kwangtung. In the north and northeast of the plateau P'u-tu Lake and the Niu-lan and Heng rivers drain northward at right angles into the Chin-sha. The elevation of the entire plateau varies from 7,000 feet at its western end to 4,500 feet on the Kweichow border, where intermontane basins provide large stretches of level country suited for agriculture. Yunnan has more lakes than most Chinese provinces, many of them formed when grabens (large areas that dropped along fault lines) filled with water. Tien Lake in K'un-ming and Erh Lake in Ta-li are among the lakes of great beauty.

Climate. Despite its tropical latitude, the eastern plateau region is noted for its moderate temperatures. Because of the high elevation, summers are cool and winters are mild. The June–July temperature averages 71° F (22° C), and the December–January temperature averages 48° F (9° C). The farmers enjoy a growing season of 10 months. In the western canyon region the high mountains and deep valleys create vertical climatic zones. Sultry heat with high humidity dominates the bottom of the valleys, a temperate zone prevails at 6,000 to 11,000 feet, and freezing winds envelop the top of the mountains. Yunnan, under the influence of rain-bearing monsoon winds blowing from both the Pacific and Indian oceans, enjoys good rainfall. The bulk of rain falls during the months from May through October, the rain being heavier in the western canyon region than in the eastern plateau region. Average annual rainfall in K'un-ming is about 49 inches (1,245 millimetres), whereas in T'eng-ch'ung it is about 58 inches.

Peter Carmichael—Aspect Picture Library London

Junk on Tien Lake at K'un-ming, Yunnan Province.

Plant and animal life. In the western canyon region, pine and other coniferous trees thrive up to 6,000 feet above sea level. Here are located some of China's largest timber reserves, covering nearly one-quarter of the province. From 6,000 to 11,000 feet above sea level, shrubs of the azalea and rhododendron family carpet the hills. The gorgeous colours of azaleas, camellias, roses, and fairy primroses make the mountain meadow country a gigantic botanical garden. At 11,000 to 15,000 feet above sea level, fir, bamboo, dwarf juniper, and flowering herbs grow on mountain podzolic (bleached) soil.

A wide variety of domesticated animals are kept in both the western canyon region and the eastern plateau region. In the tropical forests of the south, monkeys, bears, elephants, and porcupines are found in large numbers.

Settlement patterns. Approximately one-tenth of Yunnan's population is urban; the rest is rural. Following the development of industries in recent years, urban growth

has been marked by the emergence of medium-sized cities rather than giant metropolitan complexes. The only exception to this is K'un-ming, the provincial capital, which experienced significant growth due to rapid industrial development. Other important cities include Ko-chiu, the "tin capital"; Tung-ch'uan, centre of the copper industry; Hsia-kuan, the junction of highways to Tibet and Burma; and Lu-hsi, near the border with Burma.

K'un-ming, the capital

The people. Yunnan's population is noted for the great complexity of its ethnolinguistic groups. Out of the total population, the Han (Chinese) form the bulk of both the city and the agricultural population on the plains and valleys devoted to rice cultivation. Descendants of the conquering armies and immigrants who arrived through the centuries, they have both pushed back the non-Han peoples and intermarried with them. There is a large number of Hui (Chinese Muslims), the descendants of the Muslim immigrants sent in to help rule the province after the 13th century. The non-Han population of Yunnan remains substantial; it comprises more than 20 recognized nationalities and numerous other minority peoples, accounting for nearly one-third of Yunnan's population. In distribution, these groups are highly intermixed; not one county is inhabited by a single nationality.

The Yi are the largest minority group in the province. Once rulers of large parts of Yunnan, the Yi are a hill people with subsistence agriculture and proud warrior traditions. Linguistically, they belong to the Tibeto-Burman group. Second largest in population are the Pai in northwestern Yunnan. Long Sinicized, the Pai are rice cultivators who are among the original inhabitants of the region. Other peoples in the Tibeto-Burman linguistic family are the Hani, Lisu, and Lahu of the Yi subgroup; the Nasi (Na-hsi), who are a branch of the Hsi-fan subgroup; the Tibetans, who inhabit the far northwest corner of the province and practice Tibetan Buddhism; and the Ching-p'o, who speak the same language as the Kachin of upper Burma.

Speakers of Tibeto-Burman languages

A second major linguistic family represented in Yunnan is the Tai group. Most of the Tai peoples inhabit the semitropical lowlands, raise paddy rice, and practice Buddhism; they are ethnically related to the Shan tribes of Burma and the Thai (Siamese) of Thailand. Another important linguistic group is the Mon-Khmer, represented by the Wa, former headhunters who inhabit several counties along the border with Burma. The smaller Pu-lang and Peng-lung tribes also speak a Mon-Khmer language. The Miao and Yao peoples of southeastern Yunnan make up a separate linguistic group; they are hill dwellers whose traditional slash-and-burn method of clearing land for cultivation has been replaced by more sedentary farming practices. Descended from the aborigines of neighbouring Kweichow, the Miao until recently had no written language. Finally, a significant number of Chuang inhabit the southeastern part of Yunnan, adjacent to Kwangsi.

The economy. *Resources.* The province has one of the world's largest tin deposits, and the leading industry is tin mining. It is mined in the southeastern part of the province. In prewar years, China exported a major portion of the tin mined there, but now despite increased production, most goes to satisfy an increased domestic demand. Tin resources have been augmented by the discovery of additional deposits. Yunnan is also a large producer of copper, which is mined chiefly in the Hui-tse region. The copper industry in Hui-tse, which supplied most of the metal for minting coins in the Ch'ing (Manchu) dynasty (1644–1911/12), has been in the process of modernization and expansion. This has led to the creation of a special municipality at Tung-ch'uan, just south of Hui-tse. Tung-ch'uan is also the centre of lead and zinc mining.

Tin and copper production

Yunnan has moderate deposits of coal and iron, but thus far, no oil has been discovered. Other mineral products include antimony, tungsten, mercury, phosphorus, silver, placer gold, cinnabar (the ore of mercury), and manganese. Tungsten and phosphorus are mined near K'un-ming. Gypsum, sulfur, fluorite, arsenic, alum, and asbestos also exist in large quantities. Deposits of bauxite provide the basis for an aluminum industry. Marble quarried at Ta-li is eagerly sought, both as building material and as material for interior decoration. The saltpetre extracted from the rock salt mined at K'un-ming is used to make fertilizers, explosives, and food preservatives.

Agriculture. Red soil of various ages covers both the eastern and western regions of Yunnan. Although only about 6 percent of Yunnan's land is arable, the wide climatic variations assure the province a variety of crops. Rice is by far the basic food grain raised in Yunnan. In the upland plains, in the open valleys, and on the terraced hillsides, rice is the principal summer crop, with corn (maize) an important secondary crop. Other summer crops in the rice regions include sweet potatoes, vegetables, sugarcane, and tea. Winter crops in the rice regions include wheat, barley, beans, peas, and rapeseed. Among the hill peoples, corn, barley, and wheat are raised in summer in drier fields. Peaches, persimmons, walnuts, and chestnuts are also produced locally. In the extreme south, especially in the low-lying valleys, such produce as bananas, coconuts, and coffee is grown. Yunnan is one of China's major producers of tobacco; other industrial crops include cotton and hemp. The western canyon region holds enormous timber reserves and produces some tung oil. Livestock raised in Yunnan include water buffalo, ponies, mules, cattle, sheep, goats, and pigs. Ham from the city of Hsüan-wei is celebrated as a gourmet's delight.

Summer and winter crops

Industry. Manufacturing industries using traditional techniques produce paper, sugar, leather, hemp, native cloth, woolen yarn, and rugs. These traditional industries are vital to the province's economy because peasant purchasing power has increased faster than modern industry has been developed to provide items for purchase. Profiting from the government's policy of locating new industries in interior provinces with large natural resources, Yunnan has experienced great industrial growth. The K'un-ming region is a giant industrial complex, consisting of steelworks, iron- and copper-smelting facilities, and plants for manufacturing fertilizers, trucks, industrial chemicals, optical instruments, textiles, and processed foods.

Industrial growth

Transportation. Because of its rugged and broken terrain, Yunnan has long suffered from poor communications. Until World War II the only rail link with the outside world was the French-built railroad from K'un-ming to Hanoi and Haiphong in Vietnam. Since the mid-1950s, railroads have been built to link K'un-ming with both Kweichow and Szechwan and thus to other parts of China.

It is in the development of highways that Yunnan has made the fastest progress, opening links with neighbouring provinces and achieving a balanced network within the province. K'un-ming, Hsia-kuan, and P'u-erh (to the southwest) form the triangular axis of Yunnan's road system, from which radiate numerous highways. The most famous of these routes is the Burma Road, running from Hsia-kuan to Lashio in Burma. The vigorous road-development program has produced significant effects. Travel and trade with Kweichow, Kwangsi, and Szechwan have increased, and the close links with Tibet and Sinkiang have proved their strategic value. But most important has been the momentum for development and modernization in the remote regions inhabited by non-Han peoples. The slow transport of goods on men's backs or by pack animal is relied upon in the more isolated areas; but truck transport reaches most villages, making available large quantities of modern tools, fertilizers, and daily necessities to the farmers, while making it possible to ship farm products to near or distant markets where they can be sold to the best advantage of the producers.

The effects of road building

Most of the rivers in Yunnan are unnavigable, except for short distances or in broken stretches. Steam launches ply between towns on the shores of Erh Lake, but they cannot sail beyond there to connect with other waterways. Aviation, however, has added an important dimension to transportation in Yunnan. K'un-ming is the hub of both domestic and international services of the Civil Aviation Administration of China (CAAC), China's national airline.

Administration and social conditions. *Government.* Like those of the other provinces, Yunnan's administrative divisions are hierarchically organized. Immediately below the province, there are two prefecture-level municipalities

(*shih*), seven prefectures (*ti-ch'ü*), and eight autonomous prefectures (*tzu-chih-chou*), designated for various minority nationalities. At the next lower level there are municipalities (*shih*), counties (*hsien*), and autonomous counties (*tzu-chih-hsien*). The lowest political units are the villages and towns. At all levels, People's Congresses are the organs of government authority. The executive functions of government are performed by the People's Councils elected at each level by their respective People's Congresses. The Chinese Communist Party (CCP), with its own congresses and committees at every level, exercises a controlling power over this system of government.

The large number of autonomous districts and autonomous counties reflects the government's intent to end the traditional antagonism between Han and non-Han peoples. The policy seeks to preserve the language, customs, and cultural traditions of the minority peoples and to afford equal opportunity to all racial groups. Adequate representation of the nationalities on every level of government is a prerequisite. At the same time, the government is determined that the minorities should undergo the same socialist transformation as the Han majority.

Education. Besides the regular school system, spare-time schools of all types bring adult education to farms, factories, offices, and other places. Evening classes or off-work study sessions enable working people to go to school without leaving their jobs. The movement to upgrade the education of adults complements the campaign against illiteracy. A basic Chinese vocabulary in simplified strokes is taught to millions of illiterate people in short but intensive courses. For the minority peoples an effort is made to spread the knowledge of their own written language if one exists. Nonetheless, Yunnan's illiteracy rate is second only to that of Tibet, largely due to inadequate education among ethnic minorities.

The literacy campaign

In higher education, Yunnan has one "key school"—Yunnan University in K'un-ming. There is also a growing number of technical schools, among which the most prominent are the Yunnan College of Forestry, Yunnan Agricultural University, Yunnan Academy of Agricultural Science, K'un-ming Medical Colleges No. 1 and No. 2, Yunnan College of Traditional Chinese Medicine, and K'un-ming Institute of Technology. Other notable establishments of learning are the K'un-ming branch of the Academia Sinica (Chinese Academy of Sciences), the Feng-huang-shan Astronomical Observatory, and the Yunnan Provincial Library.

Health and welfare. Since 1949 Yunnan has made giant strides in sanitation and public hygiene. Such previously widespread diseases as trachoma (a contagious eye disease), smallpox, malaria, measles, snail fever, and bubonic plague have been brought under control. Iodization of water has put an end to the high incidence of goitre. In curative medicine, improvements have been slow. Clinics providing free medical care are available in all the counties, but modern hospitals are found only in the major cities. There is an expanding demand for larger medical staff, more hospital beds, and more modern equipment. The government has been promoting a massive movement to expand cooperative medical service and to collect local medicinal herbs.

Medical progress

A minimum of social welfare is available to the people. Local work-unit welfare funds provide care for the sick, the disabled, the aged, and victims of drought or flood. For industrial workers there are measures for accident prevention and insurance programs that provide for hospital treatment, sick leave, disability compensation, maternity leave, old-age benefits, and death benefits. The government has been steadily improving the housing situation and expanding recreational facilities, including hot springs, swimming pools, cinemas, and theatres.

Cultural life. Yunnan's cultural life is one of striking contrasts. Archaeologists have discovered sepulchral mounds containing magnificent bronzes at Chin-ning, south of K'un-ming, dating to the Han dynasty (206 BC–AD 220). At Chao-t'ung, in the northeastern part of the province, frescoes belonging to the Tung (Eastern) Chin dynasty (AD 317–420) also have been uncovered. Other historical landmarks of Chinese culture in subsequent ages abound. Yet the roots of the tribal life of the non-Han peoples remained untouched until the mid-20th century. Although the CCP abolished some minority practices, such as Yi slaveholding and Wa headhunting, the post-Mao Zedong policy for the liberalization of nationalities permitted many local customs and festivals to flourish again. In contrast to the period of the Cultural Revolution (1966–76), when minority culture and religious practices were repressed, Yunnan has come to tolerate and even celebrate its cultural diversity.

HISTORY

In classical antiquity, Yunnan was inhabited by aboriginal tribes that were beyond the reach of Chinese civilization though they acknowledged Chinese suzerainty under the Ch'in (221–206 BC) and Han (206 BC–AD 220) dynasties. Governmental power rested with tribal chiefs, and Chinese settlers penetrated only the eastern parts of the province. Under the T'ang dynasty (AD 618–907) a Tai kingdom, known as Nanchao, flourished in the Ta-li region. First sanctioned as a bulwark against Tibetan incursions, Nanchao eventually threatened Chinese power, which declined during the period of the Wu-tai (Five Dynasties; 907–960) and the Sung dynasty (960–1279).

The Nanchao kingdom

This state of affairs came to an end during the Yüan dynasty (1206–1368). The Mongols destroyed Nanchao in 1253, and, having named the area Yunnan, they made it a province of the Yüan Empire. Marco Polo visited the region in the latter part of the 13th century. To resettle the region, which had been depopulated by warfare, the governor brought in large numbers of Hui (Chinese Muslims) from northwestern China. Thus, the Mongol conquest drew Yunnan into the orbit of Chinese affairs but failed to reduce local interracial tension between Han and non-Han minorities.

Ming dynasty rulers (1368–1644), seeking to tighten their control over the province, used military units to promote the migration of the Chinese people from the Yangtze Valley to Yunnan. The province was governed through a system of hereditary *t'u-ssu;* that is, local leaders serving as agents of the Chinese magistrates. This policy of indirect rule was continued under the Ch'ing dynasty (1644–1911/12) and the republic (1911–49), when efforts to bring the province more thoroughly under the control of the central government were undertaken, with varying degrees of success.

Regional separatism coupled with ethnic and religious differences made Yunnan a frequent scene of strife. In 1674–78, Wu San-kuei, originally sent by the Ch'ing government to crush opposition in Yunnan, used the province as a base for rebellion against the Ch'ing government. In 1855–73 Muslims, led by Tu Wen-hsiu (alias Sultan Sulaymān), who obtained arms from the British authorities in Burma, staged the Panthay Rebellion, which was crushed with great cruelty by the Chinese Imperial troops, aided by arms from the French authorities in Tonkin. In 1915 Ts'ai Ao, onetime governor of the province, launched his drive in Yunnan to defeat the monarchist movement of Yüan Shih-k'ai, the president of the republic, who attempted to make himself emperor of China. Then, spanning the decades between World Wars I and II, the warlords T'ang Chi-yao and Lung Yün ruled the province as a satrapy, keeping it beyond the control of the central government, fostering cultivation of the opium poppy, and inflicting great suffering on the people by the collection of high taxes.

During the 19th century Yunnan fell victim to British and French imperialism. Already established in Vietnam, France regarded Yunnan as its sphere of influence and built the Hanoi–K'un-ming railway at the turn of the century to exploit the resources of the province. In 1910 the British, then established in Burma, induced the *t'u-ssu* of P'ien-ma (Hpimau) to defect from the central Chinese government and occupied his territory in northwestern Yunnan. Britain also forced China to give up a tract of territory in what is now the Kachin State of Burma (1926–27), as well as the territory in the Wa states (1940).

The era of Anglo-French imperialism

The war against Japan (1937–45) brought progress and modernization to Yunnan, as the Nationalist govern-

ment developed the province into a war base against the Japanese. Factories, universities, and government agencies were transplanted there from the coastal regions, and fresh manpower, capital, and ideas poured into the province. Industries were established, and efforts were made by the government to develop the resources of the region. The Burma Road made Yunnan the corridor through which supplies flowed to Allied war bases in all parts of China, and K'un-ming became a major U.S. Air Force base. A major advance by the Japanese Army along the upper Salween River in 1944 was halted at the city of T'eng-ch'ung, indicating the vital role that Yunnan played in the nation's defense. A decade of war forced Yunnan out of its stagnation, while its strategic location made it possible to instill the ideal of national unification in place of separatism; and the process of modernization was accelerated after the establishment of the People's Republic in 1949.

(P.-c.K./R.L.Su./Ed.)

WESTERN CHINA

Tibet Autonomous Region

Tibet, one of the autonomous regions (*tzu-chih-ch'ü*) of China, is often called "the roof of the world." It occupies about 471,700 square miles (1,221,600 square kilometres) of the plateaus and mountains of Central Asia, including Mount Everest (Chu-mu-lang-ma Feng). It is bordered by the Chinese provinces of Tsinghai to the northeast, Szechwan to the east, and Yunnan to the southeast; Myanmar (Burma), India, Bhutan, and Nepal to the south; the disputed territory of Jammu and Kashmir to the west; and the Uighur Autonomous Region of Sinkiang to the northwest. Lhasa is the capital city.

The Tibetan name for the region is Bod, and the Wade–Giles transliteration from Chinese is Hsi-tsang (Xizang in Pinyin). The name Tibet is derived from the Mongolian Thubet, the Chinese Tufan, the Tai Thibet, and the Arabic Tubbat.

Before the 1950s Tibet was a unique entity that sought isolation from the rest of the world. It constituted a cultural and religious whole, marked by the Tibetan language and Tibetan Buddhism. Little effort was made to facilitate communication with other countries, and economic development was minimal. After its incorporation into China, fitful efforts at development took place in Tibet, disrupted by ethnic tension between the Han (Chinese) and Tibetans and Tibetan resistance to the imposition of Marxist values. Official policy since the early 1980s has been somewhat more conciliatory, resulting in slightly better Han-Tibetan relations and greater opportunities for economic development and tourism. (T.W.D.S./V.C.F.)

PHYSICAL AND HUMAN GEOGRAPHY

Rugged terrain

The land. *Relief.* Tibet is on a high plateau—the Plateau of Tibet—surrounded by enormous mountain masses. The relatively level northern part of the plateau is called the Ch'iang-t'ang; it extends more than 800 miles (1,300 kilometres) from west to east at an average elevation of 15,000 feet (4,500 metres) above sea level. The Ch'iang-t'ang is dotted with brackish lakes, the largest of these being Lakes Ch'i-lin and Na-mu. There are, however, no river systems there. In the east the Ch'iang-t'ang begins to descend in elevation. The mountain ranges in southeastern Tibet cut across the land from north to south, creating meridional barriers to travel and communication. In central and western Tibet the ranges run from northwest to southeast, with deep or shallow valleys forming innumerable furrows.

The Ch'iang-t'ang is bordered on the north by the Kunlun Mountains, with the highest peak, Mu-tzu-t'a-ko (on the Tibet–Nepal border), reaching 25,338 feet (7,723 metres). The western and southern border of the Plateau of Tibet is formed by the Himalayan mass; the highest peak is Mount Everest, which rises to 29,035 feet (8,850 metres) on the Tibet–Nepal border. North of Ma-fa-mu Lake (Mapam Lake; conventional Manasarowar) and stretching eastward is the Kailas (Kang-ti-ssu) Range, with clusters of peaks, several exceeding 20,000 feet. This range is separated from the Himalayas by the Brahmaputra River, which flows across southern Tibet and cuts south through the mountains to India. (T.V.W.)

Drainage and soils. The Plateau of Tibet is a prime source of water for Central Asia. The Indus River, known in Tibet as the Shih-ch'üan Ho (in Tibetan, Sênggê Zangbo: "Out of the Lion's Mouth"), has its source in western Tibet near Mount Kailas, a mountain sacred to Buddhists and Hindus; it then flows westward across Kashmir to Pakistan. Three other rivers also begin in the west. The Hsiang-ch'üan River (Tibetan Langqên Kanbab: "Out of the Elephant's Mouth") flows west to become the Sutlej River in western India; the K'ung-ch'üeh River flows into the Kauriālā to eventually join the Ganges River; and the Ma-ch'üan River (Tibetan Damqog Kanbab: "Out of the Horse's Mouth") flows east and, after joining the

Jill Singer—CLICK/Chicago

The Plateau of Tibet looking toward the Himalayas and (right of centre) Mount Everest.

Lhasa (La-sa) River south of Lhasa, forms the Brahmaputra River.

The Salween (Nu) River has its source in east-central Tibet, from where it flows through eastern Tibet and Yunnan and then enters Myanmar. The Mekong River begins in southern Tsinghai as two rivers—the Ang and Cha—which join near the Tibet border; the river then flows through eastern Tibet and western Yunnan and enters Laos and Thailand. The source of the Yangtze River rises in southern Tsinghai, near the Tibet border; after flowing through southern Tsinghai, the Yangtze turns south to form most of the Tibet-Szechwan border.

Lakes

Among the province's lakes, the three largest are located in central Tibet, northwest of Lhasa: Lakes T'ang-ku-la-yu-mu (Tibetan Tangra Yum), Na-mu (Nam), and Ch'i-lin (Ziling). South of Lhasa lie two large lakes, Yang-cho-yung (Yamdrok) and P'u-mo (Pomo). In western Tibet two adjoining lakes are located near the Nepal border, Ma-fa-mu Lake, sacred to both Buddhists and Hindus, and Lake La-ang (Langak).

Soils are alluvial and are often composed of sand that is blown by the wind to form a layer above gravels and shingles. Colour varies from light brown to gray, according to the humus content, which is generally poor.

Climate. Although Tibetans refer to their country as Gangs-ljongs or Kha-ba-can ("Land of Snows"), the climate is generally dry, and most of Tibet receives only 18 inches (460 millimetres) of rain and snow annually. The Himalayas act as a barrier to the monsoon (rain-bearing) winds from the south, and precipitation decreases from south to north. The perpetual snow line lies at about 16,000 feet in the Himalayas but rises to about 20,000 feet in the northern mountains. Humidity is low, and fog is practically nonexistent.

Temperatures in the higher altitudes are cold, but the lower valleys and the southeast are mild and pleasant. Seasonal variation is minimal, and the greatest temperature differences occur during a 24-hour period. Lhasa, which lies at an elevation of 11,830 feet, has a maximum daily temperature of 85° F (30° C) and a minimum of −2° F (−19° C). The bitterly cold temperatures of the early morning and night are aggravated by the gale winds that blow throughout most of the year. Because of the cool dry air, grain can be safely stored for 50 to 60 years, dried raw meat and butter can be preserved for more than one year, and epidemics are rare.

Plant and animal life. The windswept Ch'iang-t'ang is devoid of trees and larger forms of vegetation. Its arid climate supports little except grasses. The varied plant life of Tibet is found in the river valleys and in the lower, wetter regions of the south and southeast. Plant life includes willows, poplars, several types of conifers, teak, rhododendrons, oaks, birches, elms, bamboo, sugarcane, babul trees, thorn trees, tea bushes, *gro-ba* (a small white tree that grows mainly in hilly regions), *'om-bu* (a bushlike tree with red flowers that grows near water), *khres-pa* (a strong durable forest tree used to make food containers), *glang-ma* (a willow tree used for basketry), and *rtsi-shing* (the seeds of which are used for making varnish). Fruit-bearing trees and certain roots are used for food, as are the leaves of the *lca-wa, khumag,* and *sre-ral,* all of which grow in the low, wet regions. Both wild and domestic flowers flourish in Tibet. Among the wildflowers are the blue poppy, lotus, wild pansy, oleander, orchid, *tsi-tog* (a light pink flower that grows at high altitudes), *shang-dril* (a bell-shaped flower, either white, yellow, or maroon, that also grows at high altitudes), and *ogchu* (a red flower that grows in sandy regions).

Animal life in the forest regions includes tiger, leopard, bear, wild boar, wild goat, stone marten (a kind of cat), langur (a long-tailed monkey), lynx, jackal, wild buffalo, *pha-ra* (a small member of the jackal family), and *gsa'* (a spotted cat that is smaller than a leopard).

In the high grasslands and dry bush areas there are brown bears, wild and bighorn sheep, mountain antelope, musk deer, wild asses, wild yaks, snakes, scorpions, lizards, and *dre-tse* (members of the wolf family). Water life includes various types of fish, frog, crab, otter, and turtle.

Birds

Undisturbed by aircraft or hunters, the bird reigns supreme in the Tibetan sky. Among the many kinds to be seen are the jungle fowl, ptarmigan, spotted tinamou, mynah, hawk, and hoopoe. Other kinds include the gull, crane, sheldrake, cinnamon teal, *sing-bya* (a tiny, owllike bird), *khra* (a crow-sized, hawklike bird), *bya-long* (a bird about the size of a duck), and *skya-ka* (a black-and-white, crow-sized bird). The *rmos-'debs*—a small, gray bird that inhabits agricultural regions—gives a call that signals the opening of the planting season.

Settlement patterns. Tibet was traditionally divided into three regions, or *Chol-kha-gsum* (*Chol-kha* means "region"; *gsum* means "three"). The Dbus-Gtsang region stretches from Mnga'-ris skor-gsum at the border of Jammu and Kashmir to Sog-la skya-bo near the town of Sog. The Khams, or Mdo-stod, region consists of the territory between Sog-la skya-bo and the upper bend of the Huang Ho (Yellow River), now located in Tsinghai Province. The A-mdo, or Mdo-smad, region reaches from the Huang Ho to Mchod-rten dkar-po in Kansu Province, comprising most of present-day Tsinghai. Tibetans say that the best religion comes from Dbus-Gtsang, the best men from Khams, and the best horses from A-mdo.

Within the three *Chol-kha-gsum* approximately one-third of the area is uninhabitable, about one-fifth is roamed by nomads, and the rest is occupied by seminomads and agriculturalists, with a small percentage claimed by trappers in the forest belt.

The main agricultural region is the 1,000-mile-long great valley of southern Tibet, stretching from the upper Indus Valley in the west to the valley of the upper Brahmaputra. Most of the agriculture, animal husbandry, and industry of Tibet is concentrated in this valley, which includes the main cities of Lhasa, Jih-k'a-tse, and Chiang-tzu.

The people. The population of the region is almost entirely Tibetan, with Han (Chinese), Hui (Chinese Muslims), Hu, Monba, and other minority nationalities. Thus, the majority of the people of Tibet have the same ethnic origin, have traditionally practiced the same religion, and speak the same language.

The Tibetan and Burmese languages are related, although they are mutually unintelligible in their modern forms. Spoken Tibetan has developed a pattern of regional dialects and subdialects, which can be mutually understood. The dialect of Lhasa is used as a lingua franca. There are two social levels of speech—*zhe-sa* (honorific) and *phal-skad* (ordinary); their use depends upon the relative social status between the speaker and the listener. Chinese has been imposed on the Tibetans since the 1960s.

Tibetan is written in a script derived from that of Indian Gupta in about AD 600. It has a syllabary of 30 consonants and five vowels; six additional symbols are used in writing Sanskrit words. The script itself has four variations—*dbu-can* (primarily for Buddhist textbooks), *dbu-med* and *'Khyug-yig* (for general use), and *'bru-tsha* (for decorative writing).

Bon is considered to be the first known religion in Tibet, although there is some argument as to the time of its establishment. It is a form of shamanism, encompassing a belief in gods, demons, and ancestral spirits who are responsive to priests, or shamans. With the rise of Buddhism, Bon adopted certain Buddhist rituals and concepts; the Buddhists also adopted certain features of Bon, so that the two religions have many points of resemblance.

Tibetan Buddhism

Although Chinese Buddhism was introduced in ancient times, the mainstream of Buddhist teachings came to Tibet from India. The first Buddhist scripture may have arrived in the 3rd century AD, but active promulgation did not begin until the 8th century. In later centuries numerous Buddhist sects were formed, including the Dge-lugs-pa sect, which emphasizes monastic discipline; in the 17th century this sect, known also as the Yellow Hats sect, gained political supremacy that lasted until 1959.

In recent times the overwhelming majority of Tibetans have traditionally been Buddhists. Before the Chinese occupation, prayer flags flew from every home and adorned the mountain slopes. Monasteries were established throughout the country, and the Dalai Lama (the spiritual head of Tibetan Buddhism) was the supreme political head of the nation. A minority, however, were adherents of Islām,

Hinduism, Bon, or Christianity. Until a moderation of policy in the 1980s the Chinese attempted to eliminate the influence of religion in Tibetan life. The Dalai Lama was forced into exile in 1959, temples were closed, religious artifacts and scriptures were destroyed, and prayer flags were temporarily taken down. (T.W.D.S./V.C.F.)

The economy. *Resources.* Although Tibet is rich in mineral resources, its economy has remained underdeveloped. Surveys of the Kailas and Ma-fa-mu-ts'o districts in western Tibet conducted in the 1930s and '40s discovered extensive goldfields and large deposits of borax, as well as reserves of radium, iron, titanium, lead, and arsenic. Subsequent investigative teams dispatched in the 1950s by the Academia Sinica (Chinese Academy of Sciences) reported the existence of a huge variety of minerals and ores. The most significant of these include a belt of iron-ore deposits located on the western bank of the Mekong River stretching for almost 25 miles south of Ch'ang-tu; graphite obtained from Ning-chin and coal reported to be plentiful around Ch'ang-tu; deposits of iron ore in concentrated seams of high quality and extractable depth found in the T'ang-ku-la Mountains on the Tibet–Tsinghai border; and oil-bearing formations, a reserve of oil shales, and lead, zinc, and manganese.

Minerals

The most valuable woodland is the Khams district, though extensive forest-clad mountains are also found in the Sutlej Valley in the southwest and in the Ch'u-mu-pi Valley in the far south. In the late 1950s some 30 kinds of trees, including those of economic value such as varnish trees, spruce, and fir, were discovered; and the estimated total of forest timber resources in the Khams area alone was placed at more than 3,510,000,000 cubic feet (100,000,000 cubic metres).

The swift-flowing rivers and mountain streams have enormous hydroelectric power potential, totaling about one-third of all China's potential hydroelectric resources. Especially promising are the Brahmaputra, Lhasa, and Ni-yang-ch'ü rivers. The coal deposits and forests represent possible sources of thermal power production, and there are vast opportunities for geothermal, solar, and eolian power production. (T.V.W./V.C.F./Ed.)

Agriculture and forestry. The staple crops are barley, wheat, and pulses; other important crops include millet, buckwheat, *rgya-bra* (a grain similar to buckwheat), beans, hemp, and mustard. Butter from the yak (large, long-haired ox) or the *mdzo-mo* (a crossbreed of the yak and the cow) is the main dairy product. The diet is supplemented by a variety of garden vegetables. Some rice is raised in the southeast. The only imported foods are tea, sugar, and rice. Most farmers keep domestic animals such as yaks, horses, mules, donkeys, and goats, and meat is obtained from cows, sheep, pigs, and chickens.

Because of the inaccessibility of Tibet's forests, forestry is developing. The forest dwellers derive their main source of income from the production of such wood products as planks, beams, printing blocks, and kitchen utensils.

Industry. Before the 1950s Tibet had no modern industries. There were small handicraft centres that were owned either individually or collectively and that produced scroll paintings, metal images, wooden block prints, and religious images. For these crafts, the *lag-shes-pa,* or craftsmen, had to be well versed in literature and mathematics. There were also carpet weavers, tanners, potters, gold- and silversmiths, carpenters, tailors, and incense-stick makers—all of whom learned their trade through apprenticeship. Because the government rewarded outstanding artists and craftsmen with official titles, estates, and money, the arts and crafts of Tibet were well preserved.

Handicraft industries

The initial steps toward industrial development came in 1952, when an iron- and woodwork factory was opened in Lhasa. This was followed by an automobile repair shop in 1957 and a tannery in 1958.

Under the Chinese government the small hydroelectric power station at Lhasa was repaired and reinforced with three generators. A new thermal station was installed in Jih-k'a-tse. Hydrographic stations in Lhasa and elsewhere were established to determine the hydroelectric potential of the Brahmaputra, Lhasa, and Ni-yang-ch'ü rivers. An experimental geothermal power station began generating electricity in the early 1980s, with the transmitting line terminating in Lhasa. In the 1980s emphasis was placed on agricultural-processing industries and tourism.

Finance. There were no banks before 1951. Small loans to be paid with interest could be obtained from local merchants, and the Tibetan government loaned public funds at interest as a means of collecting revenue. The Chinese have established branches of the People's Bank of China and have also extended agricultural and commercial credit and introduced Chinese currency. (T.W.D.S./V.C.F.)

Transportation. Before 1951 traveling in Tibet was done either on foot or on the backs of animals. Coracles (small boats made of wicker and hides) were used to cross the larger rivers. The Tibetan government obstructed the development of modern transportation to make access to the country difficult for outsiders. For trading, the Tibetans relied on the centuries-old caravan routes leading to Lhasa, of which the most important were from Tsinghai (via Na-ch'ü) and Szechwan (via Ch'ang-tu), India (via Kalimpong and Ya-tung); Nepal (via Skyid-grong and Nya-lam rdzong); and Jammu and Kashmir (via Leh and Ka-erh).

Under the Communist Chinese, a network of roads was constructed, notably the Tsinghai and Szechwan highways. Additional trunk roads have been constructed that connect Tibet to Sinkiang, Yunnan, and Nepal.

The first air link between Tibet and Peking was inaugurated in 1956. The first telegraph line was strung between Kalimpong (India) and Chiang-tzu by the British in 1904. In the 1920s another line connecting Chiang-tzu with Lhasa was erected, this being the only telegraph system in use until the Chinese took over in 1951. Postal and telecommunication stations, including mobile units, serve remote border areas and geological, hydrological, and construction teams. (T.V.W./V.C.F.)

Communications

Administration and social conditions. *Government.* Before the Chinese occupation, Tibet had a theocratic government of which the Dalai Lama was the supreme religious and temporal head. After 1951 the Chinese relied on military control and a gradual establishment of regional autonomy, which was granted in 1965.

Since 1965, as part of the separation of religion and civil administration, Tibet has been an autonomous region (*tzu-chih-ch'ü*) of China. The region is divided into the municipality (*shih*) of Lhasa, directly under the jurisdiction of the regional government, and seven prefectures (*ti-ch'ü*), which are subdivided into counties (*hsien*).

The army consists of regular Chinese troops under a Chinese military commander, who is stationed at Lhasa. There are military cantonments in major towns along the borders with India, Nepal, and Bhutan. Tibetans have been forcibly recruited into regular, security, and militia regiments.

Education. There were a few secular schools in Tibet before the Chinese established control. The monasteries were the main seats of learning, and some of the larger ones were similar in operation to theological universities. Secular facilities were established in the 1950s, including government-run primary schools, community primary schools, and secondary technical and tertiary schools including Tibet University. The state has also opened a 10-year doctoral degree program in Buddhism at the new Tibet Buddhist College.

Health and welfare. Under the health program of the Tibetan government, medical advice and medicine were provided free to expectant mothers. In addition to free vaccinations, sacred pendants known as *rims-srungs* were distributed annually to prevent epidemics. The construction and maintenance of proper drainage systems, wells, and canals—and security facilities to guard against pollution of water sources—were undertaken through the health program. Care of the kinless aged and handicapped persons was also undertaken. The Chinese have built modern hospitals, improved the drainage system, and placed mobile health units at key locations. (T.W.D.S./V.C.F.)

Cultural life. *The arts.* Tibet is most renowned for its religious scroll paintings (tankas, or *thang-ka*), metal images, and wooden block prints. There are three categories of images—representing the peaceful, moderate, and angry deities—and three schools of painting—the *Sman-*

thang, Gong-dkar Mkhan-bris, and *Kar-ma sgar-bris*—which are differentiated by colour tones and depicted facial expressions.

The rich and ancient culture is based on religion. The *Gar* and the *'cham* are stylistic dances performed by monks; they reenact the behaviour, attitudes, and gestures of the deities. Ancient legendary tales, historic events, classical solo songs, and musical debates are elaborately staged in the open air in the form of operas, operettas, and dramas. The folk songs and dances of local regions abound with colour, joy, and simplicity: the *bro* of the Khams region, the *sgor-gzhas* of the *dbus-gtsang* peasants, and the Kadra of the A-mdo area are spectacles that are performed in groups; on festive occasions they continue for several days. These cheerful performances tell of the people's loves and celebrate their faith in their religion, the beauty of their country, and the brave deeds of their ancestors.

Tibetan marriage practices

Customs. Traditional marriage ceremonies involve consultations with both a lama and an astrologer in order to predict the compatibility of a couple. The signing of a marriage contract is followed by an official ceremony at the home of the bridegroom. Appearance in a temple or before a civil authority is not required. After a couple is officially wedded, prayer flags are hoisted from the bride's side of the family upon the rooftop of the bridegroom's house to symbolize the equality of the bride in her new home. Although polygamy was practiced on a limited scale, monogamy is the predominant form of marriage.

When a death occurs, the family members make charitable contributions in the hope of ensuring a better reincarnation for the deceased. In the case of the death of an important religious figure, his corpse is preserved in a tomb. Otherwise, tradition calls for the corpse to be fed to the vultures, as a symbol of charity. The customs of burial and cremation exist but are seldom practiced.

A white scarf (*kha-btags*) is offered during greetings, visits to shrines, marriage and death ceremonies, and other occasions. The tradition was derived from the ancient custom of offering clothes to adorn the statues of deities. Gradually, it evolved into a form of greeting, and the white scarf offering, symbolizing purity, became customary. Another tradition is the hoisting of prayer flags on rooftops, tents, hilltops, and almost anywhere a Tibetan can be found. These flags signify fortune and good luck.

Food and drink. The staple Tibetan food is barley flour (*rtsam-pa*), which is consumed daily. Other major foods include wheat flour, yak meat, mutton, and pork. Dairy products such as butter, milk, and cheese are also popular. The people in the higher altitudes generally consume more meat than those of the lower regions, where a variety of vegetables is available. Rice is generally restricted in consumption to the well-to-do families, southern border farmers, and monks.

Two beverages—tea and barley beer (*chang*)—are particularly noteworthy. Brick tea from China and local Tibetan tea leaves are boiled in soda water. The tea is then strained and poured into a churn, and salt and butter are added before the mixture is churned. The resulting tea is light reddish white and has a thick buttery surface. *Chang,* which is mildly intoxicating, is thick and white and has a sweet and pungent taste.

Festivals. Festivals are both national and local in character. The many local celebrations are varied; national festivals, though fewer, are marked with a spirit of unity and lavishness.

The first day of the first month of the Tibetan calendar (February or March of the Gregorian calendar) is marked by New Year celebrations all over Tibet. Monasteries, temples, *stūpa*s (outdoor shrines), and home chapels are visited at dawn, and offerings are made before statues and relics of deities and saints. A special fried cookie known as *kha-zas* is prepared in every home. Either a real or an artificial head of a horned sheep adorns the offerings. A colourful container filled with barley flour and wheat grain and another container of *chang* are presented to all visitors, who take a pinch of the contents and make an offering to the deities by throwing it in the air.

Religious celebrations

The New Year celebrations are almost immediately followed by the Smom-lam ("prayer") festival, which begins three days after the New Year and is celebrated for 15 days. The festival marks the victory of Buddha over his six religious opponents through debates and the performance of miracles. During this festival, special prayers are offered daily. Prayers, fasting, and charitable donations mark *sa-ga zla-ba,* the celebration of the anniversary of Buddha's birth, enlightenment, and death—three events that all occurred on the 15th day of the fourth month of the Tibetan calendar.

The death of Tsong-kha-pa, founder of the Dge-lugs-pa sect, is celebrated on the 25th day of the 10th month by the burning of butter lamps on the roofs and windowsills of every house. This festival is known as *lnga-mchod.* The *dgu-gtor* festival, or festival of the banishment of evil spirits, takes place on the 29th day of the last month of the Tibetan year. At night a bowl of flour soup and a bunch of burning straws are taken into every room of every house, and the evil spirits are called out. Outside, on a distant path, the soup and straws are thrown and left to burn.

Superstitions. Superstition is prominent in Tibet. A traveler who encounters either a funeral procession, the source of running water, or a passerby carrying a pitcher of water is considered to have good fortune awaiting him. If a vulture or an owl perches on a rooftop, it is believed that death or misfortune will soon befall the household. If snow falls during a marriage procession, it is believed that the newlyweds will face many misfortunes or difficulties. A snowfall during a funeral, however, symbolizes an impediment to death in the family for a long period of time. (T.W.D.S.)

HISTORY

According to legend the Tibetan people originated from the union of a monkey and a female demon. The Chinese T'ang annals (10th century) place the Tibetans' origin among the nomadic, pastoral Ch'iang tribes recorded about 200 BC as inhabiting the great steppe northwest of China. That region, where diverse racial elements met and mingled for centuries, may be accepted as the original homeland of the Tibetans, but until at least the 7th century AD they continued to mix, by conquest or alliance, with other peoples. From that heritage two strains in particular stand out—the brachycephalic, or round-headed, peoples and the dolichocephalic, or long-headed, peoples. The former, which predominate in the cultivated valleys, may have derived from the Huang Ho basin and be akin to the early Chinese and Burmese; the latter, found mainly among the nomads of the north and in the noble families of Lhasa, seem to have affinities with the Turkic peoples, whose primitive wandering grounds were farther to the north. In addition, there are Dardic and Indian strains in the west, and along the eastern Himalayan border there are connections with a complex of tribal peoples known to the Tibetans as Mon.

Impact of Tibet on Asian history

From the 7th to the 9th century the Tibetan kingdom was a power to be reckoned with in Central Asia. When that kingdom disintegrated, Tibetans figured there from the 10th to the 13th century only casually as traders and raiders. The patronage of Tibetan Buddhism by the Yüan, or Mongol, dynasty of China made it a potential spiritual focus for the disunited tribes of Mongolia. This religious significance became of practical importance only in the 18th century when the Oyrat, who professed Tibetan Buddhism, threatened the authority of the Ch'ing dynasty throughout Mongolia. In the 19th century Tibet was a buffer between Russian imperial expansion and India's frontier defense policy.

Early history to the 9th century. Credible history begins late in the 6th century, when three discontented vassals of one of the princes among whom Tibet was then divided conspired to support the neighbouring lord of Yar-lung, whose title was Spu-rgyal btsan-po. *Btsan-po* ("mighty") became the designation of all kings of Tibet (*rgyal* means "king"; and *spu,* the meaning of which is uncertain, may refer to a sacral quality of the princes of Yar-lung as divine manifestations). Their new master, Gnam-ri srong-brtsan, was transformed from a princeling in a small valley into the ruler of a vigorously expanding military empire.

Gnam-ri srong-brtsan (*c.* AD 570–*c.* 619) imposed his au-

thority over several Ch'iang tribes on the Chinese border and became known to the Sui dynasty (581–618) as the commander of 100,000 warriors. But it was his son, Srong-brtsan-sgam-po (*c.* 608–650), who brought Tibet forcibly to the notice of T'ai-tsung (reigned 626–649), of the T'ang dynasty. To pacify him, T'ang T'ai-tsung granted him a princess as his bride. Srong-brtsan-sgam-po is famed as the first *chos-rgyal* ("religious king") and for his all-important influence on Tibetan culture, the introduction of writing for which he borrowed a script from India, enabling the texts of the new religion to be translated. He extended his empire over Nepal, western Tibet, the T'u-yü-hun, and other tribes on China's border; and he invaded north India.

Srong-brtsan's reign

In 670, 20 years after Srong-brtsan-sgam-po's death, peace with China was broken and for two centuries Tibetan armies in Tsinghai and Sinkiang kept the frontier in a state of war. In alliance with the western Turks, the Tibetans challenged Chinese control of the trade routes through Central Asia.

The reign of Khri-srong-lde-brtsan (755–797) marked the peak of Tibetan military success, including the exaction of tribute from China and capture of its capital, Ch'ang-an, in 763. But it was as the second religious king and champion of Buddhism that Khri-srong-lde-brtsan was immortalized by posterity. In 763, when he was 21, he invited Buddhist teachers from India and China to Tibet, and *c.* 779 he established the great temple of Bsam-yas, where Tibetans were trained as monks.

Establishment of Buddhism in Tibet

Buddhism foreshadowed the end of "Spu-rgyal's Tibet." The kings did not fully appreciate that its spiritual authority endangered their own supernatural prestige or that its philosophy was irreconcilable with belief in personal survival. They patronized Buddhist foundations but retained their claims as divine manifestations.

Disunity, 9th to 14th century. In the 9th century, Buddhist tradition records a contested succession, but there are many inconsistencies; contemporary Chinese histories indicate that Tibetan unity and strength were destroyed by rivalry between generals commanding the frontier armies. Early in the 9th century a scion of the old royal family migrated to western Tibet and founded successor kingdoms there, and by 889 Tibet was a mere congeries of separate lordships.

Tibetan generals and chieftains on the eastern border established themselves in separate territories. The acknowledged successors of the religious kings prospered in their migration to the west and maintained contact with Indian Buddhist universities through Tibetan scholars, notably the famous translator Rin-chen bzang-po (died 1055). In central Tibet, Buddhism suffered an eclipse. A missionary journey by the renowned Indian pandit Atiśa in 1042 rekindled the faith through central Tibet, and from then onward Buddhism increasingly spread its influence over every aspect of Tibetan life.

Inspired by Atiśa and by other pandits whom they visited in India, Tibetan religious men formed small communities and expounded different aspects of doctrine. Atiśa's own teaching became the basis of the austere Bka'-gdams-pa sect. The Tibetan scholar Dkon-mchog rgyal-po established the monastery of Sa-skya (1073), and a series of lamas (Tibetan priests) founded several monasteries of what is generally called the Bka'-brgyud-pa sect.

Hermits such as Mi-la ras-pa (1040–1123) shunned material things; but the systematized sects became prosperous through the support of local lords, often kinsmen of the founding lama, and, except for the Bka'-gdams-pa, each developed its own system of keeping the hierarchical succession within a noble family. In some sects the principle of succession through reincarnation was evolved. Although lamas of different schools studied amicably together, their supporters inevitably indulged in worldly competition. This tendency was intensified by the intervention of a new Asian power, the Mongols.

Relations with the Mongols

Although it has been widely stated that the Tibetans submitted *c.* 1207 to Genghis Khan to avert an invasion, evidence indicates that the first military contact with the Mongols came in 1240, when they marched on central Tibet and attacked the monastery of Ra-sgreng and others. In 1247, Köden, younger brother of the khan Güyük, symbolically invested the Sa-skya lama with temporal authority over Tibet. Kublai Khan appointed the lama 'Phags-pa as his "Imperial preceptor" (*ti-shih*), and the politicoreligious relationship between Tibet and the Mongol Empire is stated as a personal bond between the emperor as patron and the lama as priest (*yon-mchod*).

A series of Sa-skya lamas, living at the Mongol court, thus became viceroys of Tibet on behalf of the Mongol emperors. The Mongols prescribed a reorganization of the many small estates into 13 myriarchies (administrative districts each comprising, theoretically, 10,000 families). The ideal was a single authority; but other monasteries, especially 'Bri-gung and Phag-mo-gru of the Bka'-brgyud-pa sect, whose supporters controlled several myriarchies, actively contested Sa-skya's supremacy.

The collapse of the Yüan dynasty in 1368 also brought down Sa-skya after 80 years of power. Consequently, when the native Chinese Ming dynasty evicted the Mongols, Tibet regained its independence; for more than 100 years the Phag-mo-gru-pa line governed in its own right.

The arts

A proliferation of scholars, preachers, mystics, hermits, and eccentrics, as well as monastic administrators and warriors, accompanied the subsequent revival of Buddhism. Literary activity was intense. Sanskrit works were translated with the help of visiting Indian pandits; the earliest codifiers, classifiers, biographers, and historians appeared. In an outburst of monastic building, the characteristic Tibetan style acquired greater extent, mass, and dignity. Chinese workmen were imported for decorative work. Temple walls were covered with fine frescoes; huge carved and painted wooden pillars were hung with silk and with painted banners (tankas). Chapels abounded in images of gold, gilded copper, or painted and gilded clay; some were decorated with stucco scenes in high relief; in others the remains of deceased lamas were enshrined in silver or gilded *stūpa*s. Under Nepalese influence, images were cast and ritual vessels and musical instruments made in a style blending exuberant power and sophisticated craftsmanship; woodcarvers produced beautiful shrines and book covers, and from India came palm-leaf books, ancient images, and bell-metal *stūpa*s of all sizes.

Tibet, 14th to 19th century. *The Dge-lugs-pa* (*Yellow Hat sect*). For 70 peaceful years Byang-chub rgyal-mtshan (died 1364) and his two successors ruled a domain wider than that of the Sa-skya-pa. Thereafter, although the Phag-mo-gru Gong-ma (as the ruler was called) remained nominally supreme, violent dissension erupted again. In 1435 the lay princes of Rin-spungs, ministers of Gong-ma and patrons of the increasingly influential Karma-pa sect, rebelled and by 1481 had seized control of the Phag-mo-gru court.

Already a new political factor had appeared in the Dge-lugs-pa sect. Its founder was a saintly scholar, Blo-bzang grags-pa (died 1419), known, from his birthplace near Koko Nor, as Tsong-kha-pa. After studying with leading teachers of the day, he formulated his own doctrine, emphasizing the moral and philosophical ideas of Atiśa rather than the magic and mysticism of Sa-skya—though he did not discard the latter entirely. In 1409 he founded his own monastery at Dga'-ldan, devoted to the restoration of strict monastic discipline. Tsong-kha-pa's disciplinary reform appealed to people weary of rivalry and strife between wealthy monasteries. Tsong-kha-pa probably did not imagine that his disciples would form a new sect and join in that rivalry, but, after his death, devoted and ambitious followers built around his teaching and prestige what became the Dge-lugs-pa, or Yellow Hat sect, which was gradually drawn into the political arena.

In 1578 the Dge-lugs-pa took a step destined to bring foreign interference once more into Tibetan affairs. The third Dge-lugs-pa hierarch, Bsod-nams-rgya-mtsho, was invited to visit the powerful Tümed Mongol leader Altan Khan, with whom he revived the patron-priest relationship that had existed between Kublai Khan and 'Phags-pa. From this time dates the title of Dalai ("Oceanwide") Lama, conferred by Altan and applied retrospectively to the two previous hierarchs. The holder is regarded as the embodiment of a spiritual emanation of the *bodhisattva*—Avalokiteśvara, the mythic monkey demon and progeni-

Rise of the Dalai Lamas

tor of the Tibetans. The succession is maintained by the discovery of a child, born soon after the death of a Dalai Lama, into whom the spirit of the deceased is believed to have entered. Until 1642 the Dalai Lamas were principal abbots of the Dge-lugs-pa, and in that year they acquired temporal and spiritual rule of Tibet. With Altan's help virtually all the Mongols became Dge-lugs-pa adherents, and on Bsod-nams-rgya-mtsho's death they acquired a proprietary interest in the order and some claims on Tibet itself when the fourth Dalai Lama was conveniently discovered in the Tümed royal family.

To support their protégé the Mongols sent armed bands into Tibet. Their opponents were the Red Hat Lama, head of a Karma-pa subsect, and his patron the Gtsang king. That phase of rivalry ended inconclusively with the early death of the fourth Dalai Lama and the decline of Tümed Mongol authority in Mongolia. The next came when Güüshi Khan, leader of the Khoshut tribe, which had displaced the Tümed, appeared as champion of the Dge-lugs-pa. In 1640 he invaded Tibet, defeating the Gtsang king and his Karma-pa supporters.

The unification of Tibet. In 1642 with exemplary devotion, Güüshi enthroned the Dalai Lama as ruler of Tibet, appointing Bsod-nams chos-'phel as minister for administrative affairs and himself taking the title of king and the role of military protector. These three forceful personalities methodically and efficiently consolidated the religious and temporal authority of the Dge-lugs-pa. Lhasa, long the spiritual heart of Tibet, now became the political capital as well. Dge-lugs-pa supremacy was imposed on all other orders, with special severity toward the Karma-pa. A reorganized district administration reduced the power of the lay nobility.

The grandeur and prestige of the regime were enhanced by reviving ceremonies attributed to the religious kings, by enlarging the nearby monasteries of 'Bras-spungs, Sera, and Dga'-Idan, and by building the superb Potala palace, completed by another great figure, Sangs-rgyas rgya-mtsho, who in 1679 succeeded as minister regent just before the death of his patron the fifth Dalai Lama. By then a soundly based and unified government had been established over a wider extent than any for eight centuries.

Relations with the Manchu

The installations of the fifth Dalai Lama at Lhasa (1642) and the Ch'ing, or Manchu, dynasty in China (1644) were almost synchronous. Good relations with Tibet were important to the Manchu because of the Dalai Lama's prestige among the Mongols, from whom a new threat was taking shape in the ambitions of the powerful Oyrat of western Mongolia.

Elsewhere Lhasa's expanding authority brought disagreements with Bhutan, which held its own against Tibetan incursions in 1646 and 1657, and with Ladākh, where a campaign ended in 1684 in Tibetan withdrawal to an accepted frontier when the Ladākhī king appealed for help to the Muslim governor of Kashmir.

Tibet under Manchu overlordship. The Dalai Lama's death in 1682 and the discovery of his five-year-old reincarnation in 1688 were concealed by Sangs-rgyas rgya-mtsho, who was intent on continuing the administration without disturbance. He informed the Manchu only in 1696. Emperor K'ang-hsi (reigned 1661–1722) was incensed at the deception. In 1703 he discovered an ally in Tibet and an antagonist to Sangs-rgyas rgya-mtsho when Lha-bzang Khan, fourth successor of Güüshi, sought to assert rights as king that had atrophied under his immediate predecessors.

The behaviour of the sixth Dalai Lama, Tshangs-dbyangs-rgya-mtsho, who preferred poetry and libertine amusements to religion, gave Lha-bzang his opportunity. In 1705 with the Emperor's approval, he attacked and killed Sangs-rgyas rgya-mtsho and deposed Tshangs-dbyangs-rgya-mtsho as a spurious reincarnation. The Tibetans angrily rejected him and soon recognized in east Tibet the infant reincarnation of the dead Tshangs-dbyangs-rgya-mtsho.

In 1717 the Oyrat, nominally Dge-lugs-pa supporters, took advantage of Tibetan discontents to intervene in a sudden raid, defeating and killing Lha-bzang. Fear of hostile Mongol domination of Tibet compelled the Emperor to send troops against the Oyrat. After an initial reverse, his armies drove them out in 1720 and were welcomed at Lhasa as deliverers, all the more because they brought with them the new Dalai Lama, Bskal-bzang-rgya-mtsho. For the next 200 years there was no fighting between Tibetans and Chinese; but after evicting the Oyrat the Emperor decided to safeguard Manchu interests by appointing representatives—generally known as Ambans— at Lhasa, with a small garrison in support.

Ambans

The Tibetans, interpreting this as another patron-priest relationship, accepted the situation, which, generally left them to manage their own affairs. It was only in recurring crises that Manchu participation became, briefly, energetic. Imperial troops quelled a civil war in Tibet in 1728, restored order after the political leader was assassinated in 1750, and drove out the Gurkhas, who had invaded from Nepal in 1792. As Manchu energy declined, the Tibetans became increasingly independent, though still recognizing the formal suzerainty of the emperor, behind which it sometimes suited them to shelter. At no time did the Ambans have administrative power, and after 1792, when Tibet was involved in wars with Ladākh (1842) and Nepal (1858), the Manchu were unable to help or protect them.

Administration and culture under the Manchu. No Dalai Lama until the 13th approached the personal authority of the "Great Fifth." The seventh incarnation was overshadowed by Pho-lha, a lay nobleman appointed ruler by the Manchu; the eighth was diffident and retiring. But after the Pho-lha family's regime, Dge-lugs-pa churchmen resumed power and held onto it through a series of monk regents for about 145 years.

Chinese contacts affected Tibetan culture less than might be expected. They helped to shape the administrative machinery, army, and mail service, which were based on existing institutions and run by Tibetans. Chinese customs influenced dress, food, and manners; china and chopsticks were widely used by the upper classes. The arts of painting, wood carving, and casting figures continued on traditional lines, with much technical skill but few signs of innovation. An important effect of Manchu supremacy was the exclusion of foreigners after 1792. That ended the hopes of Christian missionaries and the diplomatic visits from British India, which had been started in 1774. Tibet was now closed, and mutual ignorance enshrouded future exchanges with its British neighbours in India.

Tibet in the 20th century. In the mid-19th century the Tibetans repeatedly rebuffed overtures from the British, who at first saw Tibet as a trade route to China and later as countenancing Russian advances that might endanger India. Eventually, in 1903, after failure to get China to control its unruly vassal, a political mission was dispatched from India to secure understandings on frontier and trade relations. Tibetan resistance was overcome by force, the Dalai Lama fled to China, and the rough wooing ended in a treaty at Lhasa in 1904 between Britain and Tibet without Chinese adherence. In 1906, however, the Chinese achieved a treaty with Britain, without Tibetan participation, that recognized their suzerainty over Tibet. Success emboldened the Chinese to seek direct control of Tibet by using force against the Tibetans for the first time in 10 centuries. In 1910 the Dalai Lama again was forced to flee, this time to India.

That dying burst by the Manchu dynasty converted Tibetan indifference into enmity, and, after the Chinese Revolution in 1911–12, the Tibetans expelled all the Chinese and declared their independence of the new republic. Tibet functioned as an independent government until 1951 and defended its frontier against China in occasional fighting as late as 1931. In 1949, however, the "liberation" of Tibet was heralded, and in October 1950 the Chinese invaded eastern Tibet, overwhelming the poorly equipped Tibetan troops. An appeal by the Dalai Lama to the United Nations was denied, and support from India and Britain was not forthcoming. A Tibetan delegation summoned to China in 1951 had to sign a treaty dictated by the conquerors. It professed to guarantee Tibetan autonomy and religion but also allowed the establishment at Lhasa of Chinese civil and military headquarters.

Chinese occupation

Smoldering resentment at the strain on the country's

resources from the influx of Chinese soldiery and civilians was inflamed in 1956 by reports of savage fighting and oppression in districts east of the upper Yangtze, outside the administration of Lhasa but bound to it by race, language, and religion. Refugees from the fighting in the east carried guerrilla warfare against the Chinese into central Tibet, creating tensions that exploded in a popular rising at Lhasa in March 1959. The Dalai Lama, most of his ministers, and many followers escaped across the Himalayas, and the rising was suppressed.

The events of 1959 intensified China's disagreements with India, which had given asylum to the Dalai Lama, and in 1962 Chinese forces proved the efficiency of the new communications by invading northeast Assam.

In 1966 and 1967 the Chinese position was shaken by Red Guard excesses and internecine fighting when the Cultural Revolution reached Lhasa. Military control was restored by 1969; and in 1971 a new local government committee was announced. Between 1963 and 1971 no foreign visitor was allowed to enter Tibet. Persecution of Tibetans abated in the late 1970s with the end of the Cultural Revolution, but Chinese repression was resumed when the Tibetans renewed their claims for autonomy and even independence. However, China has invested in the economic development of Tibet and in the early 1980s took initiatives to repair diplomatic ties with the Dalai Lama. Despite China's efforts to restore some freedoms and ease its repressive posture, riots broke out in the late 1980s, and China imposed martial law in Tibet in 1988. Tibet continues to suffer from periodic unrest, and China's suppression of political and religious freedoms has led to Western criticism and protests by human rights organizations. The Dalai Lama, still unrecognized by the Chinese government, won the Nobel Peace Price in 1989.

Tensions in Tibet

(H.E.R./V.C.F./Ed.)

Tsinghai

Tsinghai (Ch'ing-hai in Wade–Giles romanization, Qinghai in Pinyin), a province of northwestern China in the Tibetan Highlands, has an average elevation of 13,000 feet (4,000 metres). It is bounded on the north and east by Kansu, on the southeast by Szechwan, on the south and west by the Tibet Autonomous Region, and on the west and north by the Uighur Autonomous Region of Sinkiang. The province, a historic home of nomadic herdsmen, is noted for its horse breeding; it has earned new prominence as a source of both petroleum and coal.

The province derives its name from a large lake, Ch'ing-hai ("Blue") Lake, which is conventionally known as Koko Nor, in the northeast. Tsinghai has an area of about 284,600 square miles (737,000 square kilometres). It is the fourth largest political unit in China in area, though it is sparsely populated. The capital is Hsi-ning, which is 120 miles west of Lan-chou, Kansu Province.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Most of the province consists of mountains and high plateaus. In the north are the Ch'i-lien Mountains, which form the divide between the interior and exterior drainage systems of China. Through the south-central part of the province extend the Pa-yen-k'a-la Mountains (a spur of the Kunlun Mountains), which serve as the watershed of the headwaters of the Huang Ho (Yellow River). In the south the Tsinghai-Tibetan boundary parallels the T'ang-ku-la Mountains, where the Yangtze River rises. Between these high mountains are broad valleys, rolling hilly areas, and extensive flat tableland.

In the northwestern part of the province lies the Tsaidam Basin, an immense, low-lying area between the Pa-yen-k'a-la and the Ch'i-lien ranges; its lowest point is about 8,700 feet above sea level. There are many fertile spots in the piedmont and lakeside areas of the basin. The southeastern part is a broad swamp formed by a number of rivers flowing from the snowcapped T'ang-ku-la Mountains.

The extensiveness and the complex terrain of the region result in great variations in climate, soil, and vegetation. On the whole, the climate is continental, being influenced by the region's remoteness from the sea and by the mountain ranges in the south and east that bar maritime winds. The average annual precipitation in most places is less than 4 inches (100 millimetres), most of which occurs during the summer. Winter is dry, cold, and windy; summer is hot. Strong winds from the Mongolian Plateau blanket the region with sand, a serious menace to agriculture. Grass thrives on the vast plateau, however, and the region possesses some of China's best pasturelands for sheep, horses, and yaks. Antelope, wild horses, wolves, foxes, bears, and exotic birds are found there.

The people. Most of Tsinghai's population is Han (Chinese), and the rest are minority nationalities including Tibetans, Mongols, Hui (Chinese Muslims), Salar, and Tu.

The major population centres are in eastern Tsinghai in the Hsi-ning Valley, which is the main agricultural and industrial centre. A number of cities have grown substantially with development of the province's mineral and oil and natural gas industries. Since the opening of the Tsinghai–Tibet highway, Ko-erh-mu has become important.

The economy. Economically, Tsinghai is divided into two parts by the Ch'ing-hai-nan Mountains. On the eastern side is the Huang Ho drainage, consisting of large tracts of farmland crisscrossed by irrigation canals and dotted with settlements. Spring wheat, barley, and Irish potatoes are produced in much improved yields. Irrigated acreage is low, however, as is the use of chemical fertilizers. On the western side is the plateau basin, where herds of cattle, yaks, horses, and sheep—which represent the province's major source of wealth—graze on vast stretches of grassland. The output of sheep and yak wool is high and of good quality. Vast pastoral land areas have been opened up for cultivation, introducing a mixed farming-livestock economy. The Kunlun and Ch'i-lien ranges are well forested, producing spruce, birch, Chinese pine, and Chinese juniper. In the farming areas there are peach, apricot, pear, apple, and walnut orchards.

Before 1949 Tsinghai's limited industrial and commercial development was based on food and animal by-products in such centres as Hsi-ning and on a few salt mines in the Tsaidam Basin. Since then, industrial growth has been rapid. Chemical plants, iron and steel factories, and electrical equipment firms have been established in Hsi-ning and other cities. Oil and natural gas reserves are located in the Tsaidam Basin, which contains most of the province's mineral reserves. Tsinghai has become China's

Industrial growth

Yang Wumin—Xinhua News Agency

Oil derrick in the Tsaidam Basin, Tsinghai Province.

largest producer of lithium, and the province has reserves of boron, salts, potash, zinc, lead, and magnesium.

Much of the development has been made possible by the opening of new transportation links between Tsinghai and other areas of China. The crucial impetus to growth was the opening in 1959 of the Hsi-ning–Lan-chou line, connecting the province to the national rail network; the line has been extended to Ko-erh-mu and other places in the Tsaidam Basin. The Hsi-ning–Lhasa highway was widened and paved. Truck transportation is important, and main highways lead from Hsi-ning to Lan-chou, Chang-yeh in Kansu, Sinkiang, and Kan-te in Tsinghai. Several highways intersect at the southern margin of the Tsaidam Basin at Ko-erh-mu, making it a communications centre.

Administration and social conditions. The provincial capital is Hsi-ning. The province is subdivided into one prefecture (*ti-ch'ü*), six autonomous prefectures (*tzu-chih-chou*), and one municipality (*shih*) under provincial jurisdiction, which are further subdivided into counties (*hsien*) and autonomous counties (*tzu-chih-hsien*). The special status of the Tsaidam Basin was reflected in late 1956 by the establishment of a separate Tsaidam Administrative District, with its headquarters at Ta-ch'ai-tan, a new settlement situated on the northern edge of a salt swamp and at a major road junction. In 1964 the Tsaidam district was reincorporated into an autonomous district designated for the Mongol, Tibetan, and Kazak minorities.

Education

The educational system of the province includes public and temple schools. For the whole province, there are comprehensive (six-year) elementary schools and junior (four-year) elementary schools for male students only. There are elementary schools for girls. Among the ethnic groups, the Hui have the highest percentage of attendance. Temple education plays an important role in the province. Among the Tibetan Buddhists, a child who becomes a lama begins his studies at the age of 10 and continues for more than 10 years. A Muslim child's studies begin at the age of six and continue for 15 years.

Cultural life. Urban cultural institutions such as museums, theatres, universities, and libraries are few. Life is largely rural, strongly influenced by the traditional culture of the several ethnic and nationality groups that make up the population. Among the Mongols and Tibetans, for example, one son from every family is supposed to enter a lamasery. This custom imposes a limitation on population growth. The chief monastery in Tsinghai is about 20 miles from Hsi-ning. It is a centre of Tibetan Buddhism, to which thousands of believers make pilgrimages from the Inner Mongolia Autonomous Region, Tibet, Sinkiang, and Szechwan. (C.-M.H./V.C.F.)

HISTORY

The cultivable land near Koko Nor was settled in prehistoric times and may have been the original home of the tribes who settled in Tibet. The Tsinghai region, called Amdo in Tibetan, was long considered part of Tibet. The Han referred to the people of Koko Nor and beyond as Ch'iang and sought to keep them out of the Han Empire by establishing a military outpost near the lake in AD 4. The post was soon abandoned, however, and the Chinese remained ignorant of the Tsinghai region for centuries.

During the period of political fragmentation following the decline of Han power, a branch of the Hsien-pei tribe established a state based in the Tsinghai region and extending east into present-day Kansu. Called T'u-yü-hun, this state lasted more than three centuries. A Lhasa dynasty assumed control over the region in the 7th century, reaching its peak of power in the 8th century when territory was extended far to the northeast and even reached the T'ang capital of Ch'ang-an (near modern Sian, Shensi Province) for a time.

The T'ang period

Contact was friendly between Lhasa and Ch'ang-an during the T'ang period. Slow caravans of yaks and ponies carried Buddhist monks and pilgrims across the Tsinghai desert, and traders met near Koko Nor to exchange locally bred horses for Chinese tea, which was the chief Tibetan export until the 20th century.

The Tsinghai region was later ruled by Tangut leaders who established a state called Hsi Hsia, based near Koko Nor, in 1038. Genghis Khan began his campaign against this state in 1205 and incorporated it into his expanding Mongol Empire in 1227. After the Mongol conquest of North China, Tsinghai became part of the Yüan Empire based in Peking. The founder of the Dge-lugs-pa (Yellow Hat sect) of Tibetan Buddhism, Tsong-kha-pa, was born near Koko Nor in 1357; his 16th-century successor converted Mongolia to Tibetan Buddhism and was given the title Dalai Lama by the Mongolian Khan.

During the Ming period the Tsinghai region remained closely allied with Tibet, despite increased communication with China through trade and tribute missions. In 1642 a Mongolian dynasty was established in Tibet that lasted until 1717, when a local uprising caused the Chinese to directly interfere in the region's affairs. Tsinghai was placed under separate administration in 1724. During the Ch'ing period immigrants from the east settled in Tsinghai, and Chinese political and cultural influence in the region increased. Tsinghai was made a province of China in 1928. (V.C.F.)

Uighur Autonomous Region of Sinkiang

The Uighur Autonomous Region of Sinkiang (Hsin-chiang in Wade–Giles romanization, Xinjiang in Pinyin) occupies the northwestern corner of China. It is bordered by Mongolia to the northeast, Russia to the north, Kazakstan to the northwest, Kyrgyzstan and Tajikistan to the west, Afghanistan and the disputed territory of Jammu and Kashmir to the southwest, the Tibet Autonomous Region to the southeast, and the Chinese provinces of Tsinghai and Kansu to the east. China's largest political unit, it covers about 617,800 square miles (1,600,000 square kilometres). The capital is at Wu-lu-mu-ch'i (Urumchi).

Known to the Chinese as Hsi-yü (Western Regions) for centuries, the area became Sinkiang ("New Borders") upon its annexation under the Ch'ing (Manchu) dynasty in the 18th century. Westerners long called it Chinese Turkistan to distinguish it from Russian Turkistan. Sinkiang is an area of lonely, rugged mountains and vast desert basins. Its indigenous population of agriculturalists and pastoralists inhabit oases strung out along the mountain foothills or wander the arid plains in search of pasturage. Since the establishment of firm Chinese control in 1949, serious efforts have been made to integrate the regional economy into that of the nation. Despite the great increase in the Han (Chinese) population, the ethnic groups are officially encouraged to develop their own cultures.

Uighur merchant selling melons in T'u-lu-p'an, which is situated on the north side of the Turfan Depression in the Uighur Autonomous Region of Sinkiang. The information on the sign in the background is given in both Chinese and Uighur, the latter using Arabic script.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Sinkiang can be divided into five physiographic regions: the Northern Highlands, the Dzungarian Basin, the Tien Shan ("Celestial Mountains"), the Tarim Basin, and the Kunlun Mountains. These regions run roughly from east to west, the high mountains alternating with large, lower basins.

Physiographic regions

In the north the Northern Highlands extend in a semicircle along the Mongolian border. The major range in this area is the Altai Mountains, with average heights of approximately 4,500 feet (1,400 metres) above sea level. The slopes of the Altai Mountains on the Chinese (western) side are relatively gentle, with numerous rolling and dome-shaped hills.

The triangular-shaped Dzungarian Basin, or Dzungaria, with an area of some 270,000 square miles (700,000 square kilometres), is bordered by the Altai Mountains on the northeast, the Tien Shan on the south, and the A-la-t'ao Mountains on the northwest. The basin is open on both the east and west. It contains a ring of oases at the foot of the enclosing mountains and a steppe and desert belt in the centre of the depression.

The Tien Shan occupies nearly one-fourth of the area of Sinkiang. The mountains stretch into the region from Kazakstan, Kyrgyzstan, and Tajikistan and run eastward from the border for about 1,000 miles (1,600 kilometres). They are highest in the west and taper off slightly to the east. The highest peaks are Mount Han-t'eng-ko-li, which rises to an elevation of 22,949 feet (6,995 metres), and Mount Sheng-li (Russian Pik Pobedy), which attains 24,406 feet (7,439 metres). They are found in a cluster of mountains, from which ridges extend southwestward along the boundary between China and Kyrgyzstan. The Tien Shan is perpetually covered by snow, and numerous long glaciers descend its slopes from extensive snowfields.

The Tarim Basin is surrounded by the Tien Shan to the north, the Pamir Mountains to the west, and the Kunlun Mountains to the south. It occupies about half of Sinkiang, extending 850 miles from west to east and about 350 miles from north to south. The basin consists of a central desert, alluvial fans at the foot of the mountains, and isolated oases. The desert—the Takla Makan—covers an area of more than 105,000 square miles and is absolutely barren. The core of the basin has an elevation ranging from about 4,000 feet above sea level in the west to about 2,500 feet in the east. The Turfan Depression at the eastern end of the Takla Makan, however, is 505 feet below sea level.

The Kunlun Mountains form the northern rampart of the Plateau of Tibet. With elevations up to 24,000 feet, the central part of the range forms an almost impenetrable barrier to movement from north to south. There are passes on the west and east such as the Karakoram in Jammu and Kashmir and the K'u-erh-kan in Sinkiang. In the east the A-erh-chin Mountains turn northeast and eventually merge with the Tsou-lang-nan Mountains in southern Kansu Province, China.

Drainage. The drainage pattern of Sinkiang is unique to China. The only stream whose waters reach the sea is the O-erh-ch'i-ssu, which rises in north-central Sinkiang, crosses into Kazakstan, and joins the Irtysh that (in Russia) flows into the Ob, which then empties into the Arctic Ocean. Other streams in Sinkiang issue from the mountains and disappear into inland deserts or salt lakes. The principal river of the region, the Tarim, is fed by largely intermittent streams that rise in the Kunlun Mountains and the Tien Shan. It flows eastward across the Tarim Basin toward the salt-encrusted lake bed of Lop Nor.

Climate. Remote from the ocean and enclosed by high mountains, Sinkiang is cut off from marine climatic influences. It therefore has a continental dry climate. The Tien Shan separates the dry south from the slightly less arid north, so the northern slopes of the Tien Shan are more humid than those on the south.

Rainfall is not only scanty but it also fluctuates widely from year to year. Average January temperatures in the Tarim Basin are about 20° F (−7° C), compared with 5° F (−15° C) in many parts of the Dzungarian Basin. In the summer, average temperatures north of the Tien Shan are lower than they are south of the mountains. In the Dzungarian Basin, July averages vary from 70° F (21° C) in the north to 75° F (24° C) in the south. In the Tarim Basin, July temperatures average about 80° F (27° C). The hottest part of Sinkiang is the Turfan Depression, where a maximum of 118° F (48° C) and a July mean of 90° F (32° C) have been recorded.

Temperatures

Plant and animal life. Because of the great expanses of desert, the plant life of much of Sinkiang is monotonous. There are pine forests in the Tien Shan and tugrak woods in many places on the edge of the Takla Makan Desert. Apart from these trees, the most common are varieties of poplar and willow. In the Tien Shan and other mountains there is a great assortment of wild plants and flowers, many of which have never been classified.

Animal life is of greater interest, and big-game hunting is an attraction of the Tien Shan. The mountains are inhabited by antelopes, ibex (wild goats), wapiti (elks), various wild sheep, leopards, wolves, bears, lynx, and marmots. There are wild horses in the north, wild camels near Lop Nor, and wild yaks (large, long-haired oxen) and wild asses on the Tibetan frontier. Birdlife is extensive, especially in the Lop Nor district. The few varieties of fish are mostly of the carp family. Snakes are not numerous and appear to be harmless; scorpions and centipedes, however, abound. During the summer, horseflies, mosquitoes, flies, and midges are thick in the woods. A great variety of butterflies are seen in the mountains.

Settlement patterns. There are many differences in rural settlement patterns in the north and the south. Oasis agriculture in the Tarim Basin occupies a large part of the population, and only a small percentage are engaged in animal husbandry. North of the Tien Shan the grasslands support many of the inhabitants, who are pastoralists.

There are five major cities in the province. Wu-lu-mu-ch'i, the regional capital, was once an agricultural centre for the Dzungarian Basin; it has undergone considerable industrial and commercial development. K'o-la-ma-i (Karamai), also in the Dzungarian Basin, was developed in the late 1950s as a centre of the petroleum industry. Shih-ho-tzu, near the southern edge of the Dzungarian Basin, is a significant agricultural-processing centre. I-ning (Kuldja), located in the upper I-li River valley near Kazakstan, is an administrative town with a growing food-processing industry. Kashgar, the largest city of the Tarim Basin, is an ancient centre for the manufacture of handicrafts such as textiles, rugs, and tanned leather.

Cities

The people. Sinkiang is inhabited by more than 40 different ethnic groups, of which the largest are the Uighur and the Han (Chinese). Other groups include the Mongolians and Khalkha, Hui (Chinese Muslims), Kazaks, Uzbeks, Tungusic-speaking Manchu and Sibos, Tajiks, Tatars, Russians, and Tahurs.

The Han migration altered the pattern of population distribution and ethnic composition of Sinkiang. In 1953 about three-fourths of the population lived south of the mountains in the Tarim Basin. The Han influx was directed mainly to the Dzungarian Basin because of its resource potential. The Kazaks, the third largest minority group in the region, are nomadic herdsmen in the steppes of the Dzungarian Basin; they are especially concentrated in the upper I-li valley.

There are two major language groups besides Chinese in the region. The Mongolians speak languages of the Mongolian branch of the Altaic group, and the Uighur, Kazaks, and Uzbeks speak the Turkic branch of the Altaic group. The Tajiks, however, belong to the Iranian branch of the Indo-European language group. Mongolian, Uighur, and Kazak are written languages in everyday use; Mongolian has its own script, while Uighur and Kazak are written in the Arabic script.

Language groups

The largest Muslim groups in China are the Uighur and the Hui. The Kazaks and Tajiks also follow Islām, while the Mongolians are adherents of Buddhism.

The economy. Because of the dry climate, most of the cultivated land in Sinkiang depends entirely on irrigation. The various nationalities in the region have had rich experience in water conservancy techniques, of which the wells of the *qanāt* system in the Turfan and Ha-mi depressions are a fine example. Since the 1950s, these have

been greatly supplemented with canals and reservoirs, and the amount of arable land has almost tripled.

Principal crops

Sinkiang is self-sufficient in food grains. About half of the total crop area produces winter and spring wheat. Corn (maize), another important crop, is grown more in the south than in the north. Rice, kaoliang (a variety of grain sorghum), and millet are also produced in large quantities. Significant crops of long-staple cotton are produced in the Turfan Depression and the greater Tarim Basin, and cotton has become an important cash crop. Sinkiang is one of China's main fruit-producing regions; its sweet Ha-mi melons, seedless Turfan grapes, and I-li apples are well known. Sugar beets support a small sugar-refining industry. Livestock raising has been given renewed attention, particularly north of the Tien Shan.

Mineral resources include deposits of lead, zinc, and copper, as well as molybdenum and tungsten (used in strengthening steel), although none of these are of industrial significance. Gold is produced from placer and lode deposits on the southern slopes of the Altai Mountains. Sinkiang's only product of national significance is petroleum. Since the first well was developed at K'o-la-ma-i in 1955, nearly 20 fields have been developed. A major new field was discovered in the area in 1983, after which exploration for petroleum was begun in the Tarim Basin.

Petroleum reserves

Sinkiang's heavy industry includes an iron and steel works and a cement factory at Wu-lu-mu-ch'i and a farm-tool plant at Kashgar. Industries processing agricultural and animal products have been established near the sources of raw materials and include several textile mills and a beet sugar mill.

A system of roads encircles the Tarim Basin along the foothills of the surrounding mountain ranges, and roads run along the northern foothills of the Tien Shan in the Dzungarian Basin. The two basins are connected by a road that crosses the Tien Shan near Wu-lu-mu-ch'i. There are roads leading to Kazakstan in the north through passes in the Dzungarian Basin and to Tajikistan in the south through a pass near Kashgar, which was the historic gateway of the silk trade between Asia and Europe. The region is also connected by road to the Chinese provinces of Kansu and Tsinghai in the southeast.

A railway crosses Sinkiang from Kansu Province through Ha-mi, Wu-lu-mu-ch'i, and the Dzungarian Gate (a pass through the Pamir Mountains), connecting with the railway system of Kazakstan. The northern and southern sectors of the province have also been linked by a railway constructed across the Tien Shan.

Administration and social conditions. *Government.* The administrative structure of Sinkiang reflects the policies of recognition of ethnic minorities and self-administration, in which local leaders are appointed to governmental positions. The Uighur Autonomous Region of Sinkiang is divided on the subprovincial level into three types of administrative units. There are three municipalities (*shih*) under direct regional administration, five autonomous prefectures (*tzu-chih-chou*), and seven prefectures (*ti-ch'ü*). The region is further subdivided into counties (*hsien*) and autonomous counties (*tzu-chih-hsien*).

Education. Before World War II the educational system was minimal. Since 1949, educational facilities have been broadened and the literacy rate is better than the national average. Institutions of higher learning, concentrated in Wu-lu-mu-ch'i, include the Sinkiang University; the Sinkiang "August First" Institute of Agriculture, which offers a course on water conservation; the Sinkiang Institute of Minorities, which offers courses in art, Chinese language and literature, history, and science; the Sinkiang Medical College; and the Sinkiang Institute of Languages, which offers instruction in several Western languages and literatures. Standard education is supplemented by instruction broadcast over radio and television. The provincial library and museum are also in Wu-lu-mu-ch'i.

Institutions of higher learning

Cultural life. The indigenous peoples of Sinkiang exhibit their own cultures. The dominant Uighur are sedentary farmers whose social organization is centred upon the village. Many of the important Uighur cultural forms are rooted in Islām. Spoken Uighur predominates despite the popularization of Chinese. Islām itself has revived since the antireligious onslaught of the Cultural Revolution during the 1960s and '70s, and there are now numerous mosques and a new training academy for clergy. The Uighur performing arts tradition emphasizes ancient songs and dances accompanied by traditional instrumental groups. Professional troupes, first organized in the 1950s, are dominated by Uighur balladeers and dancers, although administrative duties are often performed by Han troupe members.

The Kazaks are pastoralists related to the people of Kazakstan. They migrate seasonally in search of pasturage and live in dome-shaped, portable tents known as yurts. Livestock includes sheep, goats, and some cattle; horses are kept for prestige. The basic social unit is the extended family; political organization extends through a hierarchy of chiefs. Although there is a concept of national origin, the chiefs are seldom united.

Like the Kazaks, the Mongolians are pastoralists who live in yurts, but their society is more firmly organized. The basic social unit is the nuclear family. There is an established political hierarchy of groups, the smallest of which is a group of several households known as a *bag*. The average person, or free nomad (*arat*), owes allegiance to nobles (*taiji*) and princes (*noyan* or *wang*). National power, however, is fragmented. (C.-M.H./V.C.F.)

HISTORY

Far to the northwest of the heartland of Chinese civilization, the Sinkiang region was thinly populated by herdsmen and oasis farmers organized into small kingdoms and tribal alliances. Southern Sinkiang came under the loose control of the Western Han dynasty in about 100 BC, when an extension of the Great Wall was built 300 miles west of the present Kansu-Sinkiang border. The Han capital of Ch'ang-an, near modern Sian in Shensi Province, came into contact with the Roman Empire over a trade route that passed through a series of oasis settlements south of the Tien Shan. Known as the Silk Road, this route carried Chinese silk to the Roman world in exchange for precious metals, glassware, and woolen cloth.

With the decline of Han power in the 3rd century AD, the area passed under the control of local Uighur leaders. The resurgence of Imperial power during the T'ang period (618–907) increased Chinese influence in the region, though many elements of western Asian culture were transmitted along the trade routes. The subsequent decrease of T'ang power resulted in an increase in Arab influence, and Islām gained many converts. The Turkic language came to be spoken in the oases, while Mongolian remained the language of the steppes.

Growth of Islām

Sinkiang was again incorporated into the Chinese empire when it was conquered by the Mongol leader Genghis Khan in the 13th century. The Ch'ing, or Manchu, dynasty (1644–1911/12) successfully asserted control over the Sinkiang region, defeating the resistance of stubborn tribes in the north and sending loyal Muslims from Kansu to settle in the oases of northern Sinkiang in the 17th and 18th centuries. In 1884 the Ch'ing government created a new Sinkiang province.

After the revolution of 1911–12 Yang Tseng-hsin, a Han commander of native Turkic troops, seized control of Sinkiang and was later appointed governor by the Peking government. He maintained control until his assassination in 1928, which was followed by a series of rulers and shifting allegiances. After the Communist victory in 1949, the central government implemented moderate policies toward the local minorities, and Sinkiang was established as an autonomous region in 1955. Radical policies established elsewhere in China during the Great Leap Forward (1958–60) and the Cultural Revolution (1966–76) were also implemented in Sinkiang, however. This resulted in a mass exodus of Kazak people in 1962 into Kazakstan (which then was part of the Soviet Union), massive political instability, and heightened ethnic tensions.

After the Cultural Revolution, political and economic policies were moderated, leading to widespread improvement in the livelihood of farmers and pastoralists and to relative stability and economic growth. (V.C.F.)

NORTHWEST CHINA

Hui Autonomous Region of Ningsia

The Hui Autonomous Region of Ningsia (Ning-hsia in Wade–Giles romanization, Ningxia in Pinyin), in north central China, is bounded on the east in part by Shensi; on the east, south, and west by Kansu; and on the north by the Inner Mongolia Autonomous Region. Most of the region is desert, but the vast plain of the Huang Ho (Yellow River) in the north has been irrigated for agriculture for centuries. The total area of the autonomous region is about 25,600 square miles (66,400 square kilometres). Its capital is Yin-ch'uan. Ningsia is nearly coextensive with the ancient kingdom of the Tangut people, known in China as the Hsi Hsia; after its conquest by Genghis Khan, it was named Ningsia ("Peaceful Hsia").

PHYSICAL AND HUMAN GEOGRAPHY

The land. Physiographically, the Ningsia region can be divided into two parts. Southern Ningsia is part of the Loess Plateau, with the Liu-p'an Mountains as the main ridge. The region is covered with a thick layer of loess (wind-deposited soil)—which in some places is more than 300 feet deep—and the topography is generally fairly flat. Northern Ningsia is made up for the most part of the Ningsia plain of the Huang Ho. The river enters Ningsia from the Tsinghai plateau in Kansu and flows east, then north into Inner Mongolia. West of the plain are the Holan Mountains. These mountains serve as a shelter against the sandstorms from the T'eng-ko-li Desert, which lies to the west of the mountains.

On an elevation of 3,600–3,900 feet (1,100–1,200 metres) above sea level, the Ningsia plain slopes gradually from south to north. The plain is an arid area, but the Huang Ho provides irrigation. Many canals have been built over the centuries. The network of willow-lined canals and paddy fields gives the landscape a look resembling that of southern China.

Climate

The climate of Ningsia is continental. Temperatures range from an annual average maximum of 80° F (27° C) to an annual average minimum of 7° F (−14° C). Yearly precipitation on the Ningsia plain is only about eight inches (200 millimetres).

Hui (Chinese Muslim) tradesman weighing pears in a market in Yin-ch'uan, Hui Autonomous Region of Ningsia.

The people. The ethnic composition of Ningsia includes the Han (Chinese), who constitute the majority of the population; Hui (Chinese Muslims), the largest minority group; and Manchu and small numbers of Tibetans and Mongols. Nearly all the people speak Mandarin Chinese, with some speaking Tibetan and Mongolian, and the predominant religions are Islām and Buddhism. Islām has the most believers, primarily among the Hui.

The region is predominantly rural, with most of the population engaged in pasturing and farming the land. It is one of China's more sparsely settled areas. In the widely scattered cities, residents traditionally have been devoted to handicrafts. Since 1949, however, more workers have begun to be employed in mining and manufacturing. The capital, Yin-ch'uan, is Ningsia's largest city.

The economy. The Ningsia plain produces abundant wheat and good-quality rice. An intricate system of ancient and new irrigation canals has improved agricultural yields in the region, although the use of chemical fertilizers is well below the national average. Cash crops include sugar beets. In the mixed agricultural and pastoral areas, a good breed of sheep, a domesticated form of the argali of eastern Mongolia, is raised. Its wool is soft, white, and lustrous. The Manchu especially have long been known for breeding and raising pigs. Melons and apricots are also grown in quantity.

Mineral resources of Ningsia are limited to coking coal reserves in the P'ing-lo and Shih-tsui-shan areas, near the Inner Mongolian border. Coal was mined on a small scale in the past but has been expanded since the construction of the Pao-t'ou–Lan-chou railroad in 1958. There also are reserves of gypsum, glass, and limestone.

Yin-ch'uan, in the centre of the Ningsia plain, was well known in ancient times as a border city on the western frontier of China. Until the mid-20th century it was largely a trading centre for farm and animal products. Medium-sized and small factories, including a farm-tool plant and a woolen-textile mill, have since been built there. The Huang Ho, to the east, provides irrigation and facilities for water transportation.

Industry has grown steadily. Natural resources and agricultural products such as wool and sugar form the foundation of many enterprises. The region produces consumer goods such as paper, foodstuffs, and wool and cotton fabrics. An extension of the main Peking–Pao-t'ou railway, completed in 1958, links Yin-ch'uan to two major regional industrial bases, Pao-t'ou (in Inner Mongolia, to the north) and Lan-chou (in Kansu, to the south). A highway bridge built across the Huang Ho in the 1970s near Yin-ch'uan has further stimulated economic development.

Administration and social conditions. The region has two prefecture-level municipalities (*shih*), Yin-ch'uan and Shih-tsui-shan. There are two prefectures (*ti-ch'ü*), Yin-nan and Ku-yüan. The autonomous region is further subdivided into counties (*hsien*).

Ningsia was formerly a backward area in education. In 1935 there were only two high schools, two normal schools, and about 200 elementary schools, attended by very few of the children. Since the Communist government was organized in 1949, there has been much improvement. Illiteracy has been markedly reduced. Health care also has been transformed with the building of clinics and hospitals.

Advances in education

Cultural life. Traditional Hui cultural life was intimately interrelated with Islām. The Hui woman traditionally kept house; her role was domestic, and she could not undertake outside work. When they went out, Hui women traditionally wore the veil to conceal their faces, and they were forbidden to talk to males. The traditional culture has undergone changes, however. Under the Communist regime, for example, Hui women have had to do farm work in the communes and production work in the factories.

HISTORY

The region south of the Huang Ho was incorporated into the Ch'in Empire in the 3rd century BC, at which time walls were built throughout the area. Irrigation canals on the Ningsia plains of the Huang Ho dating from the Ch'in (221–206 BC), Han (206 BC–AD 25), and T'ang (AD 618–907) dynasties provide further evidence that the area has long been inhabited. In the 11th century the area became part of the kingdom of the Tangut people, Hsi Hsia, in western China. Yin-ch'uan was captured by Genghis Khan early in the 13th century and remained tributary to China.

As Mongol power declined and Turkish-speaking Muslims migrated from oasis settlements to the west, Ningsia came increasingly under Islāmic influence. The descendants of Muslim settlers maintained their separateness from Chinese society. In the mid-19th century Ningsia became embroiled in the general Muslim revolt in the northwest, and tension between Han and Hui continued well into the 20th century. After 1911 the region came under the control of Muslim warlords, and Ningsia, as part of the "Muslim" belt, became part of the political base of the Ma clan of Ho-chou. Wooed by the Nationalist Party (Kuomintang)—to which they declared nominal allegiance—the Japanese, and the Russians, the region remained an arena of conflict throughout the period between World Wars I and II.

In 1914 the Ningsia area became a part of the province of Kansu, and in 1928 it was constituted as the province of Ningsia. During the Sino-Japanese War (1937–45) parts of Ningsia were incorporated into the Shen-Kan-Ning border region, where Communist authorities appealed for minority support by proclaiming their cultural and political rights. Although some Hui leaders joined the Communists and rose to positions of influence in the region, most Ningsia Hui supported the Ma clan. In the end, a Communist victory in Ningsia was won by the People's Liberation Army in battle with the armies of the Ma clan.

From 1949 to 1954 the province was subject to the authority of the Northwest Military Administrative Committee. Ningsia was then made directly subordinate to the central government as part of Kansu. At the same time, autonomous Hui regions were established on the east and west bank sections of the Ningsia irrigated plain and in the foothills of the Liu-p'an Mountains. In 1958 these areas were combined to form the Hui Autonomous Region of Ningsia. In 1969 Ningsia reacquired the T'eng-ko-li Desert region from Inner Mongolia; the region then reverted to Inner Mongolia in 1979. (C.-M.H./V.C.F.)

Boundary changes

Inner Mongolia Autonomous Region

Inner Mongolia (Nei-meng-ku in Wade–Giles romanization, Neimenggu in Pinyin) is one of the five autonomous regions (*tzu-chih-ch'ü*) of China. It is a vast territory, with an area of 454,600 square miles (1,177,500 square kilometres), that stretches in a great crescent for some 1,700 miles (2,700 kilometres) across northern China. It is bordered to the north by Mongolia (formerly Outer Mongolia) and Russia; to the east by the Chinese provinces of Heilungkiang, Kirin, and Liaoning; to the south by the provinces of Hopeh, Shansi, and Shensi and the Hui Autonomous Region of Ningsia; and to the west by the province of Kansu. Its capital is Hu-ho-hao-t'e (Hohhot).

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* Inner Mongolia is essentially an inland plateau with a flat surface lying at an elevation of about 3,300 feet (1,000 metres) above sea level and fringed by mountains and valleys. Its southern boundary is formed by a series of high ridges with an average height of between 4,500 and 6,000 feet. To the northwest the land falls away toward the centre of the Gobi (Desert), an arid zone with low summer rainfall, strong evaporation, almost perpetual sunshine, and constant northwesterly winds. The Huang Ho (Yellow River) makes a great northward and southward loop through south-central Inner Mongolia, delineating the Ordos Desert and providing irrigation water for the area. In the centre and the north, rainfall and snow are absorbed by the desert.

The eastern third of the region is dominated by the Greater Khingan Range, which rises from the plateau to elevations of 4,000 feet and more. Glaciation has cut many U-shaped valleys in the mountains, through which run tributaries to the Argun (O-erh-ku-na) River; the Argun forms most of Inner Mongolia's border with Russia.

Soils. Soils in the western areas are largely gray-brown or sandy desert. In the central regions, chestnut-brown soils are common, in which cereals can be raised by dry farming once every two or three years after sufficient moisture has accumulated in the soil. Soils in the higher elevations of the eastern mountains are podzolic (leached), while rich black soils and dark brown soils are found on the lower western and eastern slopes, respectively.

Climate. The seasons are marked by sharp fluctuations in the climate. Spring arrives in May and lasts for two months. Summer temperatures are relatively uniform. The July average is about 72° F (22° C) at Hu-ho-hao-t'e in the west-central part of the region; the yearly variation, however, is about 63° F (35° C). The two hottest months are July and August, when almost three-fifths of the annual precipitation occurs. Winter, which arrives after mid-September and lasts until March, is bitterly cold, with strong, icy winds blowing out of Siberia. Precipitation is meagre. In the Gobi areas the yearly total is less than four inches (100 millimetres), the plateau area receives only about 12 inches, while about 20 inches fall in the eastern mountains. The development of farming is handicapped by a frost-free period that lasts only from 110 to 160 days and by droughts, which occur almost annually.

Precipitation

Plant and animal life. Much of the western territory is barren, while the mountains in the northeast are forested. Large areas of the central region, however, consist of grassland, which provides pasture for sheep, goats, cattle, and the famous Mongolian horses and Bactrian camels. Sheep and goats (roughly in equal proportions) are by far the most important, the most ubiquitous, and the most numerous of the animals raised on the grasslands.

Settlement patterns. The region is primarily agricultural and pastoral, with few industrial centres. The three major urban areas are located in the centre of the region: Pao-t'ou, a large industrial complex and transportation hub; Hu-ho-hao-t'e, the region's political and cultural centre; and Chi-ning, a commercial and transportation centre. Also important is Ch'ih-feng, a commercial centre and

Bays Galang—Xinhua News Agency

Mongol youth tending a flock of sheep grazing on grassland in the O-wen-k'o autonomous banner in the Hu-lun-pei-erh league, Inner Mongolia. A yurt, the Mongol tent, can be seen in the centre background.

transportation hub at the southern end of the Greater Khingan Range.

The people. *Ethnic distribution.* Han (Chinese) constitute the bulk of the population, and the largest minority population is that of the Mongols. Minor groups include the Hui (Chinese Muslims), Manchu, Daghur (Ta-wo-erh) Mongol, Evenk (E-wen-k'o), Korean, and O-lun-ch'un peoples. The population is unevenly distributed, with most people concentrated in the agricultural belt south of the Ta-ch'ing Mountains escarpment of the Mongolian Plateau (near the Huang Ho) and on the eastern slopes of the Greater Khingan Range.

Because the Han greatly outnumber the Mongols, the most widely used language is Chinese. The Mongolian dialects belong to the eastern branch of Mongolian languages; they are phonetically, morphologically, and syntactically almost the same as the Khalkha Mongol dialect of Mongolia to the north. A writing system of the Mongol language, using the Cyrillic alphabet, was introduced in 1955. The system also is used in Mongolia.

Religion. In addition to ancestor worship, most of the Han in the region follow a religion formed of elements of Confucianism, Buddhism, and Taoism. The Mongols are mostly followers of Tibetan Buddhism, with almost every Mongol family having at least one son in a monastery.

Despite the prevalence of a form of Buddhism marked by ritual and a dominant, hierarchical monasticism, there are some aspects of shamanism. The stronghold of shamanism among the Mongols is the Hu-lun-pei-erh league (*meng*). The Hui, centred on Hu-ho-hao-t'e, are adherents of Islām.

The economy. *Agriculture.* Inner Mongolia, with almost one-third of China's grassland, has been traditionally renowned for its livestock. The condition of the livestock industry improved markedly after 1950 through the use of such measures as large-scale wolf hunting to reduce herd predation, the immunization of cattle, and improved pasturage and animal husbandry. Weather stations were established to forewarn herders of major storms. Cross-breeding by artificial insemination, such as between domestic and Tsgaisky pedigreed sheep, greatly improved stocks. Sheep are the main livestock raised, and cattle, horses, pigs, and camels also are important.

Livestock industry

The harsh climate severely restricts intensive agriculture. In some areas, particularly around the great loop of the Huang Ho, oats, spring wheat, kaoliang (a variety of grain sorghum), millet, and other grains are cultivated. In irrigated areas sugar beets and oil-bearing crops such as linseed, rape, and sunflowers are important. Measures to improve agricultural output have included greater implementation of water conservation and irrigation programs and the use of chemical fertilizers.

Industry. Inner Mongolia's industry is based on the territory's great mineral wealth. There are rich iron-ore deposits at Pai-yün-o-po, north of Pao-t'ou, and Inner Mongolia has one of the world's largest deposits of rare earth metals. Coal is mined near Pao-t'ou and at other locations. The inland drainage of the Mongolian Plateau once contained a number of salt lakes; most have dried up, leaving behind deposits of salt and natural alkali (soda). These resources are important for the chemical industry, especially for the manufacture of chemical fertilizers.

Industrial development is centred around Pao-t'ou, which is one of the major iron-and-steel producers in China. The city has numerous plants, including those for ceramics, cement, machine building and repairing, textiles, and chemical fertilizers. Other major industrial centres include Hu-ho-hao-t'e, Ch'i-feng, and Wu-hai.

Transportation. The rail system links the region to the remainder of China. Major railway junctions are Pao-t'ou, Hu-ho-hao-t'e, and Chi-ning. With the advent of industrial development, several new railways were constructed in Inner Mongolia. The Chi-ning and Ulaanbaatar International Railway (completed in 1955) connects China with Mongolia and with Russia. This route shortened the rail distance between Peking and Moscow by some 700 miles. The most important line constructed since 1949, however, is that from Pao-t'ou to Lan-chou in Kansu Province, which completes the rail link between northern and northwestern China.

In addition to the rail network, thousands of miles of highway link most areas. Inland waterway navigation is somewhat limited. Only the upper course of the Huang Ho, from Lan-chou, in Kansu, to Ho-k'ou, in Inner Mongolia, is navigable.

Administration and social conditions. *Government.* The administration differs in name and composition from those in other parts of China. The region is divided into eight leagues (*meng*), similar to subprovincial units in China proper, and four prefecture-level municipalities (*shih*). The local administrative units are banners (*ch'i*) in the Mongolian areas and counties (*hsien*) in the predominantly Han area. In the Mongol areas the banners are subdivided into administrative villages (*gatsaa*) or *aimak* (units of two or three villages); in the nomadic region the banners are subdivided into *sumun,* which are divided into *bag* (groups of nomad farmers), *khoto* (towns), and *ail* (settlements of a few families of nomads).

In accordance with the policy of fostering unity between the nationalities, an effort has been made to set up "democratic coalition governments" in localities where both Mongols and Han are represented in substantial numbers.

Education. Education was introduced after 1949, mainly through mobile schools and a "half-study, half-work" scheme in which study time varied according to the requirements of agriculture. More than three-fifths of the population has received at least a primary-level education, and illiteracy has been reduced. A number of vocational schools, colleges, and universities are also in operation.

Health and welfare. Most of the Mongols live in tent-like structures called yurts, or *ger,* that are inadequately ventilated. This, added to chronic shortages of drinking water and traditional hygiene patterns, contributed to the spread of epidemic diseases. Syphilis and bubonic plague caused a continuous decline in the Mongolian population in the mid-19th to mid-20th century. In 1947, for example, more than three-fifths of the pastoral population suffered from syphilis, and the infant mortality rate in 1949 was as high as one in three live births. Public health has since greatly improved, and the spread of infectious diseases has been brought under control. Energetic promotion of new midwifery methods significantly reduced the rate of infant mortality, and the population began increasing.

Conditions of pastoral life

Cultural life. Cultural life bears the deep imprint of Tibetan Buddhist influence. In liturgical music, monastery and temple architecture, scriptural learning and commentary, and religious arts, the Mongols accepted the forms of Tibet. Though the specific content and emphasis of Mongol folk legends vary somewhat with the location and with tribal or clan history concerning their origins, most clans have legends of their founders as either a mythical animal or a hero; others preserve legends about historical figures once prominent in the life of their clan. The subjects and themes of Mongol folktales and other forms of vernacular literature tend to be standard among all the tribes. A large number concern lamas and religious life. Legends and songs as well as riddles and jokes occupy the leisure time of the night camp and its fireside circle, which form a major aspect of traditional Mongolian life.

Mongolian music is not an independent art but serves solely as accompaniment to songs, dances, and rites. Singing is a form of entertainment, communication, historical recollection, group fellowship, and exuberant expression, and it demonstrates the close affiliation of individual Mongols with their culture and traditions. Mongol singing is generally a gregarious activity, mostly taking place around campfires, after the evening meal.

The Mongols observe seasonal celebrations: the New Year, the celebration of the White Month (signifying rebirth) in spring, the Midsummer Festival on the 12th day of the sixth month of the Chinese lunar calendar, the Autumn Festival (Festival of Fire) on the first day of the eighth lunar month, and the Great Sacrificial Feast to the Fire God on the 23rd day in the 12th lunar month.

Besides the temple festivals, there is the Obo (shrine) Festival, held in the fifth month of every year. Toward the end of the ceremonies the festival takes a joyful course without restraint. There are wrestling and archery competitions, and a race is held in which the young men of the

tribes ride their best horses. This is the time for a dashing display of the talent and vigour of the Mongol nomads.

With the increasing Sinicization of the region—in terms of both numbers and influence—many Han cultural forms have become prominent. Minority national troupes and a number of regional institutes seek to encourage and preserve the indigenous cultural traditions.

HISTORY

Farming was carried out on the marshes near the present boundary of Inner Mongolia and the provinces to the south in early times. The area was the limit of expansion of intensive agricultural settlement and was thus the scene of frequent confrontations between nomadic steppe dwellers and settled agriculturalists. In 658 BC several states of the North China Plain combined their efforts to build a wall defending what is now Hopeh from nomadic incursions and annexed part of Inner Mongolia to their agricultural territory. This part of Mongolia was inherited by the rulers of the Ch'in dynasty when they unified the Chan-kuo (Warring States) into an empire in the 3rd century BC.

Emperors of the succeeding Han dynasty waged war against the powerful Hsiung-nu, who were based in the valley of the northern bend of the Huang Ho. After pushing the Hsiung-nu north of the river, the Han settled the Ordos Desert region. The decline of the Han dynasty in the 3rd century AD brought a series of nomadic rulers to northern China. Later the T'ang dynasty (618–907) again asserted control over China's northern border, constricting trade and prompting border raids.

Mongolian Empire

The establishment of the Mongolian Empire by Genghis Khan in the 13th century brought prestige and expanded trade to Inner Mongolia. Old raiding patterns returned with the Ming dynasty in China, but peaceful relations with China were reestablished when the Manchu rulers of the Ch'ing dynasty reorganized the tribes into banners and leagues and promoted trade through itinerant Han merchants.

During the 19th century, population pressure to the south brought many Chinese farmers into Mongolia in search of land to cultivate. This caused conflicts with herdsmen that culminated in independence for Outer Mongolia in 1912 and administrative autonomy for Inner Mongolia in 1932. Eastern Inner Mongolia was occupied by the Japanese from 1933 as part of the state of Manchukuo, and Japanese rule extended westward after 1937 during the Sino-Japanese War.

The Inner Mongolia Autonomous Region was founded by the Chinese Communist regime in 1947, more than two years prior to the establishment of its national government at Peking in 1949. In its first configuration, it consisted of the former Chahar and Suiyüan provinces and sections taken from western Heilungkiang and northern Liaoning provinces. In a series of annexations in the 1950s, Inner Mongolia was greatly expanded to the northeast and east, west, and south; from 1956 to 1969 it extended in a great 1,700-mile arc from east of the Greater Khingan Range, then dipped to the southwest and west to the Pa-tan-chi-lin Desert in north-central China proper. During this period more than half of China's frontier with Mongolia was the Inner Mongolian border; in the northeast, a considerable section of China's international boundary with the Soviet Union—that along the Argun River—was in Inner Mongolia. In 1969 the Peking government reversed its previous policy by sharply cutting down the area of the autonomous region, transferring territory to the surrounding provinces and regions in all directions (especially to the Hui Autonomous Region of Ningsia in the west and Heilungkiang in the east). Only the international frontier with Mongolia remained unchanged. The areas transferred constituted about two-thirds of the former area of the region and contained almost half of its former population. In 1979 this reorganization was terminated, and the territory detached in 1969 was restored to Inner Mongolia.

Region of Sino-Mongolian intermixture

Inner Mongolia traditionally has been an area of mixture and contact between the agrarian Chinese and the pastoral and nomadic Mongolians. The continuous territorial changes that have affected it have therefore signified the contradiction of diverse cultures and conflicting loyalties. Inner Mongolia has thus served as a testing ground for Chinese efforts to integrate Han and Mongols into a single unified political entity.

Kansu

The province of Kansu (Kan-su in Wade–Giles romanization, Gansu in Pinyin), administratively a part of the northwest region, reaches into the geographic centre of China. It is bordered by Mongolia to the north, the Inner Mongolia Autonomous Region to the northeast, the Hui Autonomous Region of Ningsia and the province of Shensi to the east, the Chinese provinces of Tsinghai and Szechwan to the south, and the Uighur Autonomous Region of Sinkiang to the west. A vital strategic pivot, linking China proper with the vast territory in the extreme west, the narrow corridor of Kansu has served for several centuries as a passageway between the upper Huang Ho (Yellow River) area and Chinese Turkistan. Kansu covers 141,500 square miles (366,500 square kilometres). The capital of Kansu is Lan-chou, on the south bank of the Huang Ho.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Plateaus are the dominant physical features of Kansu. Along the southern border, the lofty Tsou-lang-nan and Ch'i-lien ranges separate Kansu from Tsinghai. These ranges have an average elevation of 12,900 feet (3,900 metres) above sea level. Near Lan-chou in central Kansu, the Huang Ho valley opens out, and excellent agricultural land is available. Some 120 miles (190 kilometres) northwest of Lan-chou there is a stretch of interior drainage where the land is relatively flat and where glacier-fed streams, including the Hei River, disappear into the desert; this is the area referred to as the Kansu Corridor. The higher mountains nearby are covered with forests, and their lower slopes are green with grasses, but the floor of the corridor itself is monotonously flat and barren yellow earth. Geologically, Tertiary formations (from 1.6 to 66.4 million years old) appear in a number of basins in Kansu, with strata generally composed of red clays, conglomerates, red sandstones, and gypsum.

The topographical features of Kansu are relatively uncomplicated in the west and northwest, in contrast to the southeast, where the land has suffered local dislocations from earthquakes. In the northwest there are very few mountains but rather a hilly terrain that merges into the Gobi (Desert) to the east. The average altitude is about 3,000 feet. The eastern part of Kansu is the principal centre of earthquakes in China. From the 6th century AD to the present, major earthquakes have taken place on an average of once every 65 years, while minor quakes occur at least once every 10 years. One of the greatest disasters of modern times occurred in 1920, when a violent earthquake, centred in eastern Kansu, caused great landslides. The death toll was estimated at 246,000, and many cities and towns totally vanished.

The earthquake zone

Climate. The climate in Kansu undergoes sharp fluctuations of temperature in summer (June to August) and winter (December to February), with uneven and unpredictable precipitation throughout the year. In the west the average January temperature is 18° F (−8° C) in Chiu-ch'üan, for instance, and 19° F (−7° C) in Tun-huang, 200 miles west of Chiu-ch'üan. The temperature in July in Chiu-ch'üan is 70° F (21° C), and in Tun-huang it is 81° F (27° C). Annual temperature variations for most parts of Kansu are more than 54° F (30° C).

Rainfall is meagre throughout most of Kansu. As one goes farther inland, the precipitation becomes increasingly less frequent. In the western part of the province annual rainfall ranges from two inches (50 millimetres) at Tun-huang to three inches at Chiu-ch'üan. Irrigation depends mainly on melting snow from the Ch'i-lien Mountains. The southeastern part of the province, something of an exception to the general pattern, receives a relatively abundant rainfall. In P'ing-liang, 170 miles east of Lan-chou, rainfall reaches 20 inches. Summer is usually the period of maximum precipitation.

Plant and animal life. Although vegetation is rather

limited in the mountain area, primeval forests still exist in the high mountains of the Liu-p'an range in the eastern part of Kansu. On the floor of the Kansu Corridor, willows and poplars grow along the roads and ditches. Wild animals include marmots, deer, and foxes.

Settlement patterns. The Han (Chinese) and the Hui (Chinese Muslims) are essentially agriculturists, although some engage in trade and industry. The Mongols are pastoralists or are seminomadic. Important urban areas are centred on Lan-chou. The largest city in eastern Kansu is P'ing-liang. A major centre in western Kansu is Chiuch'üan, and nearby are the respective oil and mining centres of Yü-men and Chia-yü-kuan. The population is concentrated in the Lan-chou Basin, in the fertile valley plains of the south and central sections where irrigation is possible, and in the dry terrace land of the Liu-p'an Mountains. In western Kansu, population is intensively concentrated in a number of small, isolated oases scattered along the bases of the high snow-capped ranges.

Population distribution

The people. The Han constitute the main racial group in Kansu. Other ethnic groups are the Monguors (Mongols), the Turks (Salars and Sarig Uighurs), and the Tibetans. There are Mongols to the west of Lan-chou and Tibetans scattered over an area enclosed by the Chuang-lang, Ta-t'ung, and Huang rivers.

The Han majority tends to follow the same traditional religious practices, such as Buddhism, generally observed elsewhere in China. The most important minority group in Kansu is the Hui, living mostly in the north and west; some are of Arab, Turkish, or Mongol origin. A few Muslims are converted Chinese. The Hui include believers in both the Sunnī and Shī'ah traditions. Tibetans and Mongols follow Tibetan Buddhism. Almost every Tibetan family has at least one son in a Buddhist monastery.

Most of the ethnic groups, including the Tibetan minority, speak Chinese as a second language. The Monguors, however, whose language differs completely from either Western or Eastern Mongolian, rarely speak a second language. Hui use both Chinese and Arabic scripts, although Arabic is usually used only for religious purposes.

Hui villages

Village life among the Han inhabitants is generally similar to that elsewhere in North China. In Hui villages, however, the religious-communal life-style is distinctly different. There is a small public building that serves as a mosque, where children gather regularly to receive religious instruction and to learn the alphabet and phonetics. Hui villages are, by comparison, more organized and possess more community spirit than is usual in the Han villages. Hitherto the two peoples have been mutually segregated.

Tibetan villages, in many aspects, are similar to Han villages. Those Tibetans who are sedentary, however, have no clearly defined clan organization, and their family ties are much looser than among the Han.

Village dwellings are generally mud huts. Some people live in caves—which may be elaborate, with fine furnishings, or simply scooped out of the porous yellow earth cliffs. Brick structures predominate in cities and towns. The eating habits of the people are slightly different from those of the Chinese in other parts of the nation. Coarse grains and wheat flour, rather than rice, are consumed.

The economy. Traditionally, Kansu has been an area of poverty. The frequency of earthquakes, droughts, and famines has contributed to the economic instability and low agricultural productivity of the region. Endowed with rich mineral resources, however, Kansu is building itself into a vital industrial base to support the exploitation of the province of Tsinghai to the south and the Uighur Autonomous Region of Sinkiang to the far west.

Resources. Kansu's minerals of greatest value are the oil reserves of Yü-men, in northwestern Kansu, and coal reserves, the chief mine of which is located about 20 miles south of Lan-chou. There is a large deposit of iron ore in the Tsou-lang-nan Mountains area in western Kansu. Other mineral resources include nickel, copper, lead, zinc, antimony, and rare earth metals. There are also deposits of limestone, gypsum, quartz, and other materials used in construction.

Agriculture. Although it is predominantly an agricultural area, and despite the fact that the per capita landholding is much larger than the national mean, output of food grain is insufficient to feed the population. The extent of cultivation in different areas depends on the elevation, the steepness of the slope of the land, and the dryness of the climate. High elevation has a greater precipitation and is therefore more favourable for farming. Terracing is prevalent and is practiced on about one-fifth of all of the cultivated land. Much of the hill land is cultivated by the use of a modified form of contour plowing. Because the slopes of the fields are so steep, however, and the fields so extensive, erosion is a serious problem, and some of the land has been abandoned. Agriculture in this area depends on the improvement of irrigation.

Agricultural resources

Some modernization has taken place since 1949, including increased irrigation and mechanization and the introduction of chemical fertilizers. The fertile Kansu Corridor produces most of the province's food crops, which include wheat, barley, millet, corn (maize), and tubers. The province is also a modest producer of sugar beets, rapeseed, soybeans, and a variety of fruits. Attempts have been made to increase agricultural output by transforming vast areas of wasteland along the Kansu Corridor into cotton fields. More than one-third of this area is suitable for cotton. In addition, wool and tobacco are produced as cash crops. Kansu is famous for its water-pipe tobacco, which is raised near Lan-chou and farther west. Kansu's vast grasslands support large herds of livestock, about half of which are sheep. Bactrian (two-humped) camels are raised in the Kansu Corridor.

Industry. Since 1950 strenuous efforts have been made

Li Shengcai—Xinhua News Agency

Bactrian (two-humped) camels grazing in the Kansu Corridor as a train passes.

to develop Kansu into an industrial base for northwestern China, with Lan-chou as its focus. A traditional regional centre located at the crossroads to Central Asia and the old Silk Road, Lan-chou has been a processing centre and entrepôt for centuries. Modern industrial development began only with the arrival of the railroad to Lan-chou in 1952 and its penetration through the Kansu Corridor to Yü-men and beyond in the mid-1950s. During the mid-1950s emphasis was placed on establishing heavy industry in Lan-chou. The city became a major producer of petroleum and now has dozens of other large modern industrial enterprises, including plants that produce petroleum drilling and refining equipment, locomotive equipment, chemical fertilizers, and petrochemicals. Efforts have also been made to build Lan-chou into a base for nuclear industry. Other important industrial installations in Kansu include the oil refinery at Yü-men and the iron-and-steel plant at nearby Chiu-ch'üan.

Transportation. The major barrier to development in this area has been the absence of transportation facilities. Before 1952 only the Lung-hai Railway connected Kansu with the coastal area; in that year an extension between Lan-chou and T'ien-shui to the southeast was completed. In addition, a railway extends northwestward from Lan-chou via Yü-men to Wu-lu-mu-ch'i, the capital of Sinkiang. Railways have also been built connecting Lan-chou to the Inner Mongolia Autonomous Region and to the rich mineral area of the Tsaidam Basin in northwest Tsinghai. The highway system has also been greatly expanded. Highways radiate from Lan-chou toward Tsinghai, Sinkiang, Inner Mongolia, Shensi, and Szechwan. Because of considerable silting and the river's seasonal flow, navigation on the Huang Ho is limited to the section between Lan-chou and Chung-wei.

Railway construction

Administration and social conditions. *Government.* From 1949 to 1954 Kansu was subject to the authority of the Northwest Military Affairs Commission. After 1954 the province came directly under the jurisdiction of the central government in Peking. Lan-chou, however, remained a military regional headquarters.

The provincial government has its headquarters in Lan-chou. Three municipalities (*shih*) are under the direct supervision of the provincial government—Lan-chou itself; Chia-yü-kuan, at the western terminus of the Great Wall (which runs from northwest to southeast through the province); and Chin-ch'ang in the central sector of Kansu. Intermediate administrative divisions include eight prefectures (*ti-ch'ü*) and two autonomous prefectures (*tzu-chih-chou*)—the Lin-hsia-hui-tsu Autonomous Prefecture, inhabited by Hui, and the Kan-nan-tsang-tsu Autonomous Prefecture, inhabited by Tibetans. On the third level of administration the province is further divided into counties (*hsien*), autonomous counties (*tzu-chih hsien*), and municipalities (*shih*) under county jurisdiction.

Education. The educational standard is comparatively lower than elsewhere in North China, and the percentage of people with at least a primary-level education is well below the national average. Since 1950 educational facilities have been greatly expanded, however. Universities and colleges are mostly located in Lan-chou, including Lan-chou University, the Northwest Normal College, and the Northwest Institute for Minorities. Special colleges providing training for railway work, the petroleum industry, animal husbandry, and veterinary medicine are also established in Lan-chou.

Health and welfare. By Western standards, the area is backward in health and sanitation. The most common diseases are the fecal-borne intestinal diseases spread through the use of human waste as fertilizer. The shortage of water supplies and the lack of modern doctors, nurses, and pharmacists constitute a serious problem. The state has funded projects to dig wells and channel water in afflicted areas.

Welfare is more concerned with the victims of natural disasters than with the poor in general. Frequent earthquakes and severe droughts require the government to assume responsibility for relief. In the Hui community, a part of the public welfare is organized by the Muslims themselves; Muslim officials collect obligatory charity for this purpose. Since 1949 the government has made general progress in Kansu with its welfare program for workers and peasants. New residential areas, for instance, have been built in Chiu-ch'üan for families of workers in the Yü-men oil fields. Medical clinics have been established in remote areas, where most people previously relied on local herb doctors.

Cultural life. Kansu represents a colourful mixture of races, customs, and cultures. The land abounds with mosques, monasteries of lamas, and Chinese temples.

Communal life in Han villages is marked by religious observances, particularly rituals connected with ancestor worship; seasonal celebrations, such as the New Year, the Dragon Boat Festival, and the Moon Festival; and customs relating to birth, marriage, funerals, and burials. All of these activities are similar to those of the Han throughout the nation. Village theatricals provide another type of communal activity.

Religious festivals

Most of the Monguors and Tibetans have abandoned their nomadic way of life and have become sedentary villagers. They live in brick and mud houses resembling their former tents (yurts). Tibetans insist on simultaneous group actions within the village. Every year, when the first day of spring planting is determined by the horoscope, for instance, the villagers go to the fields in their best clothing. The fields are then plowed simultaneously, and the seeds are sown at the same time in each field. During the course of the growing season, the villagers periodically parade through the fields carrying holy books on their heads.

The Hui are faithful followers of Islām and strictly observe the month-long fast of Ramaḍān, during which they abstain from food, drink, and sexual intercourse between sunrise and sunset. Before darkness falls, pious, bearded men say their prayers in public, and one or two of the elders may preach on points of theology, quoting the Qur'ān in oddly mutilated Arabic. At nightfall a communal feast is eaten; the community fires blaze all night, and people call and shout to one another. Among the Hui, the *ḥājjīs*, those who have completed the pilgrimage to Mecca, are highly respected in the community. The number of pilgrimages has, however, decreased considerably since 1949.

The western part of Kansu has long been a region renowned for ancient and classic artistic works. Stone caves in Tun-huang have many kinds of religious paintings on their walls, dating from the T'ang dynasty (AD 618–907). In Wu-wei large numbers of writings on bamboo slips have been found on the sites of the old frontier garrisons of the Han Empire (206 BC–AD 220). In 1964 a coherent bamboo text comprising a large part of one of the classic works on ritual (the *I Li*) came to light in western Kansu. In Tun-huang, within a Buddhist cave-temple, a library was discovered that had been immured there in the year 1035. It consisted of voluminous rolls of texts, including many valuable paintings and Buddhist classics.

HISTORY

Kansu became a part of Chinese territory during the Ch'in dynasty (221–206 BC), when Chinese power began to extend up to the Kansu Corridor and into the region of modern Ningsia and Tsinghai. In ancient times all traffic between China proper and the far west was funneled through the Kansu Corridor. Along the ancient Silk Road that began at Ch'ang-an (modern Sian) and continued through the corridor, camel caravans carried the tea, silk, and porcelain of China to bazaars in the Middle East and even to the markets of Byzantium and Rome. In the train of these caravans such travelers as the Buddhist missionary Kumārajīva and the Venetian merchant Marco Polo entered China.

The name of Kansu first came into existence in the Yüan, or Mongol, dynasty (1206–1368), when it comprised the districts of Kan-chou and Su-chou. In the Ch'ing dynasty (1644–1911/12) Kansu covered the later provinces of Kansu, Ningsia, a part of Tsinghai, and a part of Sinkiang. The area was under the administration of a governor general of Shensi-Kansu, who was stationed at Lan-chou and had authority over both provinces. One of the most prominent governors general was Tso Tsung-t'ang (1812–85), who after 1878 brought a half century of peace to Kansu. A hero in the suppression of the Taiping

Tso Tsung-t'ang

Rebellion, Tso also helped the Ch'ing court to put down the Muslim rebellion in Kansu, which lasted for 16 years (1862–78) and affected more than 10,000,000 people.

Before Tso assumed the governorship, Kansu was an area without law and order. The Hui in Kansu were in open rebellion, committing murder, arson, and numerous other crimes. After having effectively destroyed their strongholds, Tso extended Chinese educational and civil service systems into the conquered districts for the benefit of Hui and non-Hui alike. As a result, the violence subsided and peace prevailed.

Kansu remained a province of China during the period of the Chinese republic (1911–49). The territory, however, shrank substantially when Sinkiang, Tsinghai, and Ningsia became independent provinces in 1928. During the 1920s and '30s the province was controlled by Muslim warlords. The provincial leader, Ma Chung-ying, of the Ma clan of Ho-chou, Kansu, was wooed by both the Japanese and Russians, but Ma came to accept nominal Nationalist Party (Kuomintang) authority in the region.

Communist influence in Kansu began in 1935, after the Chinese Red Army withdrew from southeast China to Shensi, and a Communist-controlled Shensi–Kansu–Ningsia border government was established in the late 1930s. In the final stages of the civil war, the People's Liberation Army defeated Ma's troops and took Lan-chou in August 1949.

The area within Kansu's jursidiction has undergone several changes since 1950. In 1954 Kansu annexed the province of Ningsia. In 1956 the A-la-shan-yu Ch'i and O-chi-na Ch'i banners in northwestern Kansu were detached and incorporated into the Inner Mongolia Autonomous Region. In 1958 the affixed Ningsia Province was separated from Kansu to become the Hui Autonomous Region of Ningsia. In 1969 the two aforementioned banners were returned to Kansu again, leaving the territory of Kansu almost unchanged when compared with its 1950 area. In 1979, however, the banners received a decade earlier from Inner Mongolia were again detached from Kansu and transferred to Inner Mongolia.

(C.-y.C./V.C.F./Ed.)

Shensi

Shensi (Shaan-hsi in Wade–Giles romanization, Shaanxi in Pinyin) is a province of China, bordered by the Inner Mongolia Autonomous Region to the north, by the Huang Ho (Yellow River) and Shansi Province in the east, by Szechwan Province in the south, by Hupeh and Honan provinces in the southeast, and by the Hui Autonomous Region of Ningsia and Kansu Province on the west. Its total area is 79,400 square miles (205,600 square kilometres). The capital is Sian.

PHYSICAL AND HUMAN GEOGRAPHY

The three natural regions

The land. *Relief and drainage.* Shensi Province comprises three distinct natural regions—the mountainous southern region, the Wei River valley, and the northern upland plateau.

The mountainous southern region forms the drainage area of the upper Han River, which is a northern tributary of the Yangtze. The Han flows between two mountain complexes that structurally form part of a great, single fold zone. These complexes are the Ta-pa Mountains, forming the boundary with Szechwan Province to the south, and the Tsinling Mountains—the major environmental divide between northern and central China—to the north. The Ta-pa Mountains range from 5,000 to 6,000 feet (1,500 to 1,800 metres) in height, with individual peaks reaching altitudes of up to 8,000 feet. Its northern flank in Shensi is heavily dissected by the complex pattern of the Han River's southern tributaries. The only major break in this mountain chain occurs in the far southwest of the province where the Chia-ling River, which rises to the north in the Tsinling Mountains, cuts through the Ta-pa chain to flow into Szechwan on its way to join the Yangtze at Chungking. This valley forms the major communication route from the Wei Valley in central Shensi to Szechwan and the southwest.

The Han Valley itself broadens out near the city of Han-chung into a fertile and densely cultivated basin about 60 miles (100 kilometres) long and 10 miles broad. Farther downstream the valley again narrows, after which the river flows between mountains and through deep gorges, only emerging into the plain once more in Hupeh Province.

The Tsinling Mountains to the north of the Han Valley form an even more impressive barrier than the Ta-pa range. Structurally a continuation of the great Kunlun Mountains to the west, the range runs continuously across Shensi from west to east at an average height of some 8,000 feet, with individual peaks reaching 12,300 feet. The range merges into the Fu-niu and the Hsiung-erh Mountains in Honan. The main watershed of the range is in the north; the southern slope of the range, draining into the Han, is deeply sculptured by an extremely complex drainage pattern. Three major passes cross the Tsinling Mountains: the San-kuan Pass south of Pao-chi, which leads to the Chia-ling Valley and thus into Szechwan; the Kao-kuan Pass south of Sian, which leads to the Han-chung Basin; and the Lan-t'ien Pass southeast of Sian, which affords a route to Nan-yang in Honan and to northern Anhwei Province.

The Wei Valley

The second major region is the valley of the Wei River, a tributary of the Huang Ho, which flows from west to east across the province from its headwaters in Kansu to join the Huang Ho at the border with Shansi and Honan. This valley is a major geological trough, bounded on the south by a vast complex of faults and fractures along the base of the Tsinling Mountains; it is a zone of considerable seismic instability, especially vulnerable to earthquakes. The northern border of the Wei River trench is less abrupt, and the large northern tributaries of the Wei, Ching, and Lo rivers, have themselves formed in their lower courses quite extensive alluvial plains that are continuations of the Wei River plain. The plain consists largely of loess (which also mantles parts of the northern face of the Tsinling Mountains), as well as of redeposited loess washed off the plateau to the north. The rivers are heavily silted.

The third region, to the north, is the great upland plateau of northern Shensi. Structurally this is a basin of largely undisturbed sedimentary rocks of immense thickness. Its raised western rim forms the Liu-p'an Mountains, which extends from the far west of Shensi northward into Kansu and Ningsia. A minor northwest-to-southeast axis forms the Ta-liang and Huang-lung ranges, which constitute the watershed between the Lo River system and the northern part of the province, which drains directly into the Huang Ho. On the eastern border of the basin the Huang Ho flows from north to south through a narrow, gorgelike trough. In this section it falls some 2,000 feet in less than 500 miles, and it is mostly unnavigable, with frequent rapids, culminating in a very deep, narrow gorge and falls at Lung Gorge.

The whole of this basin plateau, which is mostly above 3,000 feet, is a peneplain (a region reduced almost to a plain by erosion) covered with a deep mantle of loess, blown from the Gobi and the Ordos Desert by the prevailing northwesterly winds of the winter season. Much of the area is covered to a depth of 150 or even 250 feet, and the loess completely masks the original relief and structure of the region. The loess, in turn, has been heavily eroded, leaving a characteristic landscape of almost vertical walls, cliff faces, and deep ravines. This erosion has been intensified by the effects of human occupation, which have destroyed the natural vegetation cover.

Climatic regions

Climate. The Tsinling Mountains are not only a physical divide but also separate Shensi into two sharply differentiated climatic regions. The southern mountain area has a subtropical climate, similar to that of the Middle Yangtze Basin or of Szechwan. Mean temperatures in January are from 37° to 39° F (3° to 4° C), and the frost-free growing season is from 260 to 280 days, although the summer and autumn are not so hot as in the Middle Yangtze region. Total precipitation is between 30 and 40 inches (750 and 1,000 millimetres), falling mostly between May and October. The driest part of the year is spring and early summer, when irrigation is necessary. But in general the climate is hot and moist. The rugged and varied topography, however, produces great local variations.

The Wei Valley has a much drier and somewhat colder climate. Average winter temperatures are about 32° F (0° C), and the frost-free period lasts for about 240 days. Total precipitation is between 20 to 25 inches, mostly falling between May and October, with a sharp peak in September and October. Rainfall is generally deficient in spring and early summer, but the climate is not seriously dry. It is, however, an area subject to severe and prolonged droughts. On the Loess Plateau farther north and west the climate grows progressively drier and colder. The extreme north and west have only about 10 inches of annual precipitation, most of which occurs in late summer and autumn, when evaporation loss is at its maximum. The growing season and frost-free period become progressively shorter until in the north the former is only about 190 days. In this area agriculture depends on techniques for minimizing evaporation losses and in conserving moisture in the soils. The northern frontier with the Inner Mongolia Autonomous Region, roughly coinciding with the line of the Great Wall, remains an important cultural divide. Beyond it conditions for agriculture become extremely precarious.

Vegetational zones

Plant and animal life. The vegetation in the northern and southern zones is also sharply differentiated. The southern mountain area forms a part of the mixed deciduous broad-leaved and evergreen forest zone that formerly covered the Lower Yangtze and Han river basins; this region is characterized by a rich variety of vegetation that includes more than 50 broad-leaved genera and a dozen or more coniferous genera. Owing to the difficulty of access, large areas of natural timber remain standing.

The northern slopes of the Tsinling Mountains and the lower Wei Valley were originally covered with deciduous broad-leaved forest. The bulk of northern Shensi, except for the pure steppe (treeless plain) of the northern and western borders, was originally part of the so-called northwestern forest-steppe area, where deciduous broad-leaved woodland grows only on the highest ground and around watercourses, most of the area being covered by grass or low, drought-resistant scrub. This northern area has been intensively cultivated since the 1st millennium BC, and its natural vegetation has been virtually destroyed.

The people. The people are nearly all Han (Chinese) and speak the Northwest Mandarin dialect. Some Hui (Chinese Muslim) communities remain in the south and northwest of the province. Most of the population is settled in the Wei and Han valleys; the uplands are more sparsely settled. The chief cities are Sian, Pao-chi, Hsien-yang, T'ung-ch'uan, and Han-chung. Other cities include An-k'ang, San-yüan, Yen-an, Wei-nan, and Yü-lin. Most of the province's county seats are very small. Sian is the provincial metropolis and the main communication centre and chief industrial city. It has an important university, a medical college, and an institute of art and music, as well as libraries and museums. Pao-chi is an important road and rail transportation centre. San-yüan and Hsien-yang are both satellite cities of Sian, as well as rail and road transport centres. Han-chung is the main communication and administrative centre for the southern region.

The economy. *Resources.* The basin in the north of the province has enormous coal reserves, second in size only to those of Shansi. Important modern mines are those at T'ung-ch'uan, on the northern slope of the Wei Valley, and at Han-ch'eng, near the Huang Ho. There are minor coal and oil-shale deposits in the Han Basin in the south, where there are also iron-ore deposits. The Tsinling Mountains contain some minor gold-producing areas (mostly in the west), as well as some minor deposits of manganese and other minerals. There are also significant deposits of molybdenum, graphite, zeolite, limestone, and barite.

Agriculture. The southern part of the province forms a portion of the southwestern highland and basin area, which is characterized by double-cropping, wet-field agriculture, and forestry production. Most of the cultivated land is below 3,000 feet. The Han-chung Basin grows rice intensively, followed by winter wheat, but in the mountain zones of the T'ai-pai and Tsinling ranges the main cereal crops are corn (maize) and winter wheat. Such subtropical crops as tea, tung oil, and citrus fruits are grown, as are a variety of other fruits.

The Wei Valley area is very intensively cultivated. Well over half of the total area is under cultivation, and it supports a dense agricultural population. The valley area produces some rice, good winter wheat, tobacco, and cotton, but millet, barley, and corn are also increasingly important crops, as is kaoliang (a variety of grain sorghum). On the higher ground, millet, oats, and buckwheat are common. Hemp, sesame, sugar beets, and rapeseed are important subsidiary crops, particularly in the upper Wei and the Ching valleys. Normally three crops are raised every two years.

The northern plateau is too cold in the winter for winter wheat to survive. It forms a part of the Inner Mongolia dry agricultural and pastoral zone. Spring-sown wheat and millet are the main grain crops, and these depend largely on the availability of irrigation water. Grazing becomes particularly important toward the northern and western borders, and the growing season is so short that only one crop yearly is possible.

Shensi's output and agricultural income remain below the national average, but improvements in a province known for famine and natural disaster have been considerable. Since the mid-1950s much attention has been directed toward stopping and reversing the extensive soil erosion that has long plagued the province north of the Tsinling Mountains. A large-scale multipurpose conservancy scheme has been underway on the Huang Ho, designed to reduce the enormous silt load discharged into the Huang by the Wei and its other west-bank tributaries. A great effort has been made to spread terraced cultivation in Shensi. The plan also calls for the construction of numerous dams in the loess uplands to retain silt before it reaches the Huang Ho. These small dams quickly silt up, forming new farmland. In addition, projects have been initiated to sow grass on denuded land, to plant trees for the protection of new terraced fields and slopes, and to prevent gullying. Even more ambitious is a plan to plant a belt of trees a mile or more wide, mostly consisting of drought-resistant poplar, elm, or willow, in an attempt to contain the spread of sand dunes from the Ordos Desert. This belt extends southwestward for about 375 miles from northeastern Shensi across Ningsia and into Kansu, skirting the edge of the desert. The irrigation system has also been greatly extended. The ancient irrigation systems of the Wei and Ching valleys, restored (after centuries of neglect) following the famine of 1932, have been extended, while great numbers of small dams and wells have also been constructed to increase the irrigated area.

The irrigation system

Industry. The major industrial area in Shensi is that centred around Sian. Principal industries in this area include cotton and other textiles, electrical equipment, engineering and chemical manufacturing, and iron and

Richard and Sally Greenhill—Black Star

Young Han (Chinese) woman at work in a cotton mill in Sian, Shensi Province.

steel production. There are minor centres of industry at Pao-chi and at Shih-ch'üan in the Han Valley, near An-k'ang, and Yao-hsien, near T'ung-ch'uan, has a large and important cement plant. A small petroleum refinery is located at Yen-ch'ang. The production of consumer goods in Shensi has been emphasized, including bicycles, radios, televisions, watches, and apparel.

Transportation. The Wei Valley since prehistoric times has formed part of the main east–west route running from the North China Plain in the east to the Kansu Corridor and the steppelands in the west. Sian is a natural centre, where the great route east to west meets the routes that cross the Tsinling Mountains to the south and southeast, an alternative route to the northwest via the Ching Valley, and routes to the Ordos region in the north and to Shansi in the northeast. All these routes are now followed by modern highways. In the south a highway crosses the province from east to west, joining Han-chung with Wuhan, in Hupeh Province to the east, and Lan-chou, in Kansu Province to the west. In the far southwestern corner of Shensi, a main highway follows the route of an ancient post road from Pao-chi to Ch'eng-tu in Szechwan.

Road and rail routes

The first railway to reach Shensi was the Lung-hai line, the great east–west trunk line from the sea at Lien-yün-kang in Kiangsu, via the industrial centres of Honan. This line, extended in the 1930s through the Wei Valley to Pao-chi, was largely destroyed during the war with Japan. It was reconstructed in the late 1940s and extended westward to Kansu. A branch was also constructed from Hsien-yang to the coalfields at T'ung-ch'uan. Another major line now extends from Pao-chi to Ch'eng-tu in Szechwan, where it links with various lines to the southwest. Sian has become an important regional centre of air traffic.

The special districts

Administration and social conditions. The province has three prefecture-level municipalities (*shih*) directly subordinated to the provincial government. One of these municipalities includes the provincial capital, Sian. The rest of the province is organized into seven prefectures (*ti-ch'ü*); the northern plateau area is divided between the Yü-lin Prefecture in the far north and the Yen-an Prefecture farther south; the central and eastern Wei Valley is divided into the prefectures of Hsien-yang and Wei-nan; and the mountainous southern area is divided into the Han-chung, An-k'ang, and Shang-lo prefectures. At the next administrative level the province is divided into counties (*hsien*) and municipalities (*shih*) under the jurisdiction of prefectural governments. For purposes of economic planning, the province, together with Kansu and the Uighur Autonomous Region of Sinkiang, forms part of the northwestern economic region.

Culture. Citizens of Shensi take pride in their region as a historic centre of Chinese civilization and in their distinctive traditions in art, ceramics, and folksinging. The Yang-ko is a local form of musical folk opera with comic themes. Shensi-style Ch'in-ch'iang opera is also popular, as are shadow plays using local leather puppets.

HISTORY

Northern Shensi. *The early period.* The northern parts of Shensi, particularly the Wei Valley, were some of the earliest settled parts of China. In the valley some remains of the Mesolithic Period have been found, while there are Neolithic Yang-shao culture sites spreading along the whole of the west–east corridor from Kansu to Honan, showing that this was already an important route. Chinese Neolithic culture was probably first developed in the Wei Valley. It remained an important centre of the later Neolithic Lung-shan culture and then became the first home of the Chou people, who in the late 12th century BC invaded the territories of their overlords, the Shang, to the east, and set up a dynasty in 1111 that exercised some degree of political authority over much of North China. Until 771 BC the political centre of the Chou was at Hao, near modern Sian.

For the early agriculturalists, working the ground with primitive stone-tipped tools, the slopes of loess and river terraces provided ideal farmland—light, stone-free, and fertile. The natural cover, too, was mostly grass and scrub and could be easily cleared for temporary cultivation.

After the 8th century BC the Chou lost much of their authority and moved their capital eastward to Lo-yang in Honan Province, after which Shensi became something of a backwater. Gradually, however, the predynastic Ch'in state, which controlled the area, began to develop into a strong centralized polity of a totally new kind, able to mobilize mass labour for vast construction projects, such as the part of the Great Wall of China built between Shensi and the Ordos Desert. One of the greatest of these tasks was the completion in the Wei Valley of a large and efficient irrigation system based on the Cheng-kuo and Pai-kung canals and centred around the junction of the Ching and Wei rivers. This system, completed in the 3rd century BC, watered some 450,000 acres (180,000 hectares) and provided the powerful economic base for the Ch'in's eventual conquest of the whole of China.

Ancient construction projects

The middle period. In 221 BC Hsien-yang, in Shensi, became the capital of the Ch'in dynasty, which unified China for the first time; it was a city of vast wealth and the focus of a nationwide road system. The area remained extremely populous and was a major centre of political authority for the next millennium. The Han (206 BC–AD 220), successors of the short-lived Ch'in dynasty, made their capital Ch'ang-an, near Hsien-yang. Later, in the 6th century, when after some centuries of disunion the Sui (581–618) again unified the empire, their capital—Ta-hsing—was on the same site as Ch'ang-an, which also was the capital of the T'ang (618–907). Ch'ang-an, as the capital was now once more known, was by far the largest and most magnificent city in the world in its day and was immensely wealthy. But by this time the irrigation system upon which Shensi primarily depended had begun to deteriorate, soil erosion and deforestation had begun to be problems, and the productivity of the area declined. The maintenance of a huge metropolis of more than 1,000,000 people in the area consequently necessitated the difficult and costly transportation of vast quantities of grain and provisions from the eastern plains and the Yangtze Valley. The capital remained in Shensi largely because the area (known as Kuan-chung—literally "Within the Passes") was easily defended and was of crucial importance, as a frontier with China's neighbours. After the sack of Ch'ang-an in 882, however, no dynasty ever again had its capital in the northwest, and the area rapidly declined in importance as the economic centre of the empire gradually gravitated toward the Yangtze Valley and the South. During the next millennium Shensi became one of the poorest and most backward of China's provinces.

The early modern period. Under the Mongols in the 13th century Shensi as a provincial unit assumed approximately its present form, incorporating the area formerly known as Shan-nan (literally "South of the Mountains"), or Li-chou. During this era, however, Shensi underwent many changes. In the course of the Yüan, or Mongol, dynasty (1206–1368) the province was devastated and largely depopulated as a result of the Mongol conquest. Subsequently there emerged a large Muslim element in the population. The area suffered badly from rebellion and disorders following the collapse of Mongol rule after about 1340, when two independent regimes—those of Chang Ssu-tao in the northwest and of Li Ssu-chi around Ch'ang-an—controlled most of Shensi. Later it was one of the areas in which disaffection with Ming rule (which began in 1368) first appeared in the late 1620s, and it was somewhat badly damaged in the fighting leading up to the Ch'ing conquest in 1644. Under Ming rule Shensi Province also incorporated Kansu, but under the Ch'ing dynasty (1644–1911/12) the two were separated once more.

The 19th and 20th centuries. By the 19th century Shensi was seriously impoverished. Although only marginally affected by the Taiping Rebellion (1850–64) in its last stages, eastern and southern Shensi were slightly disturbed by the Nien Rebellion between 1853 and 1868. It then suffered the terrible Muslim rebellion of 1862 to 1878, which affected much of the western and northern parts of the province. Although the effects of the rebellion and its savage suppression were not as terrible as in Muslim Kansu, about 600,000 were killed in Shensi, and the resulting destruction left the province in serious plight.

Periodic famines

As this rebellion was coming to an end, Shensi was also affected by one of the worst drought famines of modern times. It had virtually no rain from 1876 to 1878, and, when the government tried to remedy the situation in 1877, poor transport facilities prevented effective relief. Perhaps 4,000,000 or even 5,000,000 people died in Shensi alone, with some single counties in the fertile Wei Valley losing more than 100,000 people each. As a result of the terrible death toll in the last decades of the 19th century, Shensi became a haven for a wave of land-hungry immigrants from Szechwan and Hopeh provinces.

The end of the empire in 1911 brought yet further deterioration in living conditions. In 1912 the governors of Shensi and Kansu became engaged in a destructive civil war of an unusually brutal and violent character; the war, often affecting the whole province, continued until 1921, after which the province became involved in a still larger war between Yü-hsiang Feng and the Chihli warlords. In 1926 the capital, Sian, was besieged and badly damaged; the death toll numbered nearly 100,000 from starvation alone.

In the earlier years of the 20th century Shensi also suffered badly from periodic famines, which occurred in 1915, in 1921, and finally in 1928. This last famine was as severe as that of 1877–78; it is estimated that at least 3,000,000 people died of starvation, after which a wave of epidemics increased the death toll still further. Whole counties were virtually depopulated. This time, however, some measures of relief were forthcoming. The International Famine Relief Organization began to rehabilitate the derelict irrigation system of the Wei Valley, while the extension of the Lung-hai Railway into the province meant that, if in the future famine should threaten, relief supplies could quickly be moved into the province.

A further political upheaval followed in 1936 when Communist armies, driven out of their bases in Kiangsi, passed through the western parts of Shensi. They then established themselves in Yen-an in northern Shensi, which was to be the base from which they conducted their war of resistance against the Japanese and from which, after the end of World War II, they successfully undertook the conquest of all China. In Shensi itself they controlled the territory of the present Yen-an and Yü-lin prefectures from 1937 onward.

Communist base at Yen-an

Southern Shensi. The history of the southern part of the province has been considerably more placid than that of the north. Until the late 17th century the area was very sparsely peopled, and much of it, apart from the Han-chung basin, is still virgin forest. In the period after about 1680 the introduction of corn (maize) and sweet potatoes, followed in the 18th century by the introduction of the Irish potato, made upland farming possible. A pattern emerged of growing rice in the valley bottoms, corn on the lower mountain slopes, and Irish potatoes on the higher land. Southern Shensi, with its great amounts of vacant land, attracted immigrants on a large scale after severe famines and crop failures had occurred in Hupeh and Szechwan provinces in the 1770s. In the early 19th century immigrants from central and southern China constituted as much as 90 percent of the population in some parts of Southern Shensi.

Rapid and often reckless development of the uplands, however, often led to soil erosion, rapid loss of fertility, and declining crop output. Local disaffection broke out in the so-called White Lotus Rebellion of 1796–1804, which was centred in the Szechwan–Shensi–Hupeh–Honan border regions. After its suppression, however, the area remained generally peaceful: in the 20th century it escaped the worst excesses of the northwestern warlords' civil wars, as well as of the repeated famines that occurred in northern Shensi. (D.C.T./V.C.F.)

(1982); WILLIAM HINTON, *Fanshen: A Documentary of Revolution in a Chinese Village* (1966), an eyewitness account of 1948 revolutionary activity in a village in Shansi; MARC BLECHER, *China, Politics, Economics, and Society* (1986), a survey of China since 1949; FRANZ SCHURMANN, *Ideology and Organization in Communist China*, 2nd enlarged ed. (1968), a sociological analysis of Communist ideology and institutions on the eve of the Cultural Revolution; PING-TI HO and TANG TSOU (eds.), *China's Heritage and the Communist Political System* in *China in Crisis*,

vol. 1 (1968), a critical analysis of the Chinese political system during the early phase of the Cultural Revolution; JOHN WILSON LEWIS (ed.), *Party Leadership and Revolutionary Power in China* (1970), analyses of the early impact of the Cultural Revolution on the Chinese Communist leadership and its policies; RICHARD H. SOLOMON, *Mao's Revolution and the Chinese Political Culture* (1971), an examination of Mao's thought as applied to the problems of political socialization of the masses; JOHN M.H. LINDBECK (ed.), *China: Management of a Revolutionary Society* (1971), studies of cultural, ideological, and institutional changes; HARRY HARDING, *Organizing China: The Problem of Bureaucracy, 1949–1976* (1981); JAMES R. TOWNSEND, *Politics in China*, 2nd ed. (1980), a summary of works on all aspects of political history; BENEDICT STAVIS, *China's Political Reforms* (1988), an analysis of some of the reforms of the 1980s; HARVEY W. NELSEN, *The Chinese Military System*, 2nd rev. ed. (1981), an examination of decision making in the People's Liberation Army; ELLIS JOFFÉ, *The Chinese Army After Mao* (1987), an assessment of the PLA's modernization; PI-CHAO CHEN, *Population and Health Policy in the People's Republic of China* (1976); DANIEL L. OVERMYER, *Religions of China: The World as a Living System* (1986), an introduction to religion in everyday life; and KENNETH LIEBERTHAL and MICHEL OKSENBERG, *Policy Making in China* (1988), an analysis of the influence of political institutions on policy making.

The following periodicals give current information on social, political, cultural, and economic affairs: *The China Quarterly; Far Eastern Economic Review* (weekly); *The China Business Review* (bimonthly); *China Today* (monthly); *China Pictorial* (monthly); and *China News Analysis* (biweekly).

(C.-S.Ch./K.G.L./K.P.S./E.I.U./K.J.De.W.)

History. *General works:* DENIS TWITCHETT and JOHN K. FAIRBANK (eds.), *The Cambridge History of China* (1978–), will be the standard multivolume reference work for all aspects of Chinese history when it is completed. The following are comprehensive works: JOHN K. FAIRBANK, *China: A New History* (1992), covering the span from paleolithic cultures to the events in Tiananmen Square in 1989, with an excellent bibliography; WOLFRAM EBERHARD, *A History of China*, 4th ed. (1977, reissued 1987; originally published in German, 1948); JOHN K. FAIRBANK and EDWIN O. REISCHAUER, *China: Tradition and Transformation*, rev. ed. (1989); OTTO FRANKE, *Geschichte des chinesischen Reiches*, 2nd ed., 5 vol. (1948–65); JACQUES GERNET, *A History of Chinese Civilization* (1982; originally published in French, 1972), a detailed survey of China's intellectual, social, and economic history from the neolithic cultures up to the Cultural Revolution of 1966; CHARLES O. HUCKER, *China's Imperial Past: An Introduction to Chinese History and Culture* (1975), to 1850; and JOHN MESKILL (ed.), *An Introduction to Chinese Civilization* (1973), which includes a survey of Chinese history and ten essays on such aspects of Chinese civilization as anthropology, economy, geography, and religion, among others.

Prehistory: Scholarly analyses include CHI LI, *The Beginnings of Chinese Civilization* (1957, reprinted 1968); KWANG-CHIH CHANG, *The Archaeology of Ancient China*, 4th ed., rev. and enlarged (1986), a pioneering, comprehensive synthesis based on the coverage of excavations reported to the end of 1985; DAVID N. KEIGHTLEY (ed.), *The Origins of Chinese Civilization* (1983), a collection of articles about environment and agriculture, cultures and peoples, and the genesis of the state; JESSICA RAWSON, *Ancient China: Art and Archeology* (1980), a study of the artistic significance of Neolithic and Bronze Age artifacts; WILLIAM WATSON, *Cultural Frontiers in Ancient East Asia* (1971), an illustrated analysis of cultural interaction; and RUKANG WU and JOHN W. OLSEN (eds.), *Palaeoanthropology and Palaeolithic Archaeology in the People's Republic of China* (1985), an account of Chinese research on early man.

The first historical dynasty: the Shang: In addition to the works of Chang, Watson, and Rawson mentioned above, the following works are also informative: KWANG-CHIH CHANG, *Early Chinese Civilization: Anthropological Perspectives* (1976), and *Shang Civilization* (1980), on Shang archaeology and culture; TSUNG-TUNG CHANG, *Der Kult der Shang-Dynastie im Spiegel der Orakelinschriften* (1970); DAVID N. KEIGHTLEY, *Sources of Shang History: The Oracle-Bone Inscriptions of Bronze Age China* (1978, reprinted 1985); WEN FONG (ed.), *The Great Bronze Age of China* (1980), an analytic catalog of an exhibition from the People's Republic of China; and PAUL WHEATLEY, *The Pivot of the Four Quarters* (1971), a comparative study of the origins of urban society. (D.N.K.)

The Chou and Ch'in dynasties: This transitional period is examined in CHI LI, *The Formation of the Chinese People* (1928, reprinted 1967), useful for information on the ethnic history of ancient China; HERLEE GLESSNER CREEL, *The Birth of China* (1937, reprinted 1954), still regarded as one of the standard references, and *The Origins of Statecraft in China*, vol. 1 (1970), the first Western book to include extensive materials from bronze inscriptions—especially significant on the activities of non-Chou peoples; CHO-YUN HSU, *Ancient China in Transition* (1965), a standard work on social structure and social mobility in the Chou period; DERK BODDE, *China's First Unifier* (1938, reprinted 1967), and *Statesman, Patriot, and General in Ancient China* (1940, reprinted 1967), works covering the effort of the first emperors and their courts to accomplish unification; ARTHUR COTTERELL, *The First Emperor of China* (1981), a popular history that includes a description and historical analysis of 7,000 terra-cotta life-size figures buried in 210 BC; YU-NING LI, *The First Emperor of China* (1975), YU-LAN FUNG, *A History of Chinese Philosophy*, 2nd ed., 2 vol., trans. from the Chinese (1952–53, reprinted 1983), coverage of the thought of different schools in ancient China; and XUEQIN LI, *Eastern Zhou and Qin Civilizations* (1986), an account of archaeological findings of the period from the 8th to the 3rd century BC. (C.-y.H.)

The Han dynasty: Translations of historical source material can be found in ÉDOUARD CHAVANNES (ed. and trans.), *Les Mémoires historiques de Se-ma Ts'ien*, new ed; 6 vol. (1967–69); HOMER H. DUBS (ed. and trans.), *The History of the Former Han Dynasty*, 3 vol. (1938–55); ESSON M. GALE (ed. and trans.), *Discourses on Salt and Iron* (1931, reprinted 1973); BURTON WATSON (ed. and trans.), *Records of the Grand Historian of China*, 2 vol. (1961); HSIEN-YI YANG and GLADYS YANG (trans.), *Selections from Records of the Historian* (1979); and A.F.P. HULSEWÉ, *Remnants of Ch'in Law* (1985). Works on specific topics of Han history include HANS BIELENSTEIN, *The Restoration of the Han Dynasty*, 4 vol. (1953–79); MICHAEL LOEWE, *Records of Han Administration*, 2 vol. (1967), *Everyday Life in Early Imperial China During the Han Period 202 B.C.–A.D. 220* (1968, reissued 1973), and *Crisis and Conflict in Han China 104 B.C. to A.D. 9* (1974); T'UNG-TSU CH'U, *Han Social Structure* (1972); A.F.P. HULSEWÉ, *Remnants of Han Law* (1955); CHO-YUN HSU, *Han Agriculture: The Formation of Early Chinese Agrarian Economy, 206 B.C.–A.D. 220* (1980); and YING-SHIH YU, *Trade and Expansion in Han China* (1967). ZHONGSBU WANG, *Han Civilization* (1982), is a survey of archaeological investigations of the Han dynasty. (J.L.D.)

Period of division: The most extensive modern account of the period of division is that found in the general history cited above by Franke, vol. 2, with copious notes in vol. 3; this is a traditional chronological history, which pays little attention to nonpolitical matters and absolutely none to modern historical writing on the period in Chinese and Japanese. Other works on this important period include WOLFRAM EBERHARD, *Das Toba-Reich Nordchinas: eine soziologische Untersuchung* (1949), a Western-language study on the T'o-pa Wei—controversial and interesting but highly technical; W.J.F. JENNER, *Memories of Loyang* (1981), a political history of the Wei dynasty during the Pei-ch'ao (Northern Dynasties) period; ÉTIENNE BALAZS, "Les Courants intellectuels en Chine au IIIe siècle de notre ère," *Études Asiatiques*, vol. 2 (1948), the best Western-language study on the rise of "Neo-Taoism" and other schools of thought after the breakdown of the Han Empire; HENRI MASPERO, *Taoism and Chinese Religion* (1983; originally published in French, 1950), a collection of essays dealing mainly with T'ang dynasty Taoism, still the most important general survey of the Taoist religion of this period, written mainly in the 1930s and '40s by a great authority for the general public; HOLMES WELCH, *Taoism: The Parting of the Way*, rev. ed. (1965), a general history of the Taoist movement with about one-third of the book devoted to the development of Taoist religion in the Six Dynasties period; MICHEL STRICKMANN, *Le Taoïsme du Mao Chan: chronique d'une révélation* (1981), a scholarly account of one of the main schools of medieval Taoism; ARTHUR F. WRIGHT, *Buddhism in Chinese History* (1959, reprinted 1971), a popular but authoritative survey of Chinese Buddhism as a whole, two chapters of which are devoted to the Six Dynasties period; KENNETH K.S. CHEN, *Buddhism in China* (1964, reprinted 1972), an extensive history of Chinese Buddhism by an eminent specialist; ERIK ZÜRCHER, *The Buddhist Conquest of China*, 2 vol. (1959, reprinted 1972), a detailed, rather technical study of the formation of gentry Buddhism; and JACQUES GERNET, *Les Aspects économiques du bouddhisme dans la société chinoise du Ve au Xe siècle* (1956), an indispensable but rather technical work on the economic functions of the Buddhist monasteries from the 5th to the 10th century. (E.Z./D.C.T.)

Sui and T'ang periods: By far the best general history of the periods is in vol. 3 of *The Cambridge History of China* (1979). The most important work on the Sui period is ARTHUR F. WRIGHT, *The Sui Dynasty* (1978). See also his two studies "The Formation of Sui Ideology 581–604," in JOHN K. FAIRBANK (ed.), *Chinese Thought and Institutions* (1957), and "Sui Yang-ti: Personality and Stereotype," in ARTHUR F. WRIGHT (ed.), *The Confucian Persuasion* (1960). WOODBRIDGE BINGHAM, *The Founding of the T'ang Dynasty: The Fall of Sui and Rise*

of T'ang (1941, reprinted 1970), gives a clear account of the period from 607 to 624. Two books by C.P. FITZGERALD, *The Son of Heaven: A Biography of Li Shih-Min, Founder of the T'ang Dynasty* (1933, reprinted 1971), and *The Empress Wu,* 2nd ed. (1968), give a traditional account of the political history of the early T'ang, without advantage of later scholarship. More modern analyses of the early T'ang are presented in HOWARD J. WECHSLER, *Mirror to the Son of Heaven: Wei Cheng at the Court of T'ang T'ai-tsung* (1974), and in his *Offerings of Jade and Silk: Ritual and Symbol in the Legitimation of the T'ang Dynasty* (1985). R.W.L. GUISSO, *Wu Tse-t'ien and the Politics of Legitimation in T'ang China* (1978), is a comprehensive study of Empress Wu's reign. On the Empress' use of Buddhist ideology, see A. FORTE, *Political Propaganda and Ideology in China at the End of the Seventh Century* (1976). EDWIN G. PULLEYBLANK, *The Background to the Rebellion of An Lu-shan* (1955, reprinted 1982), gives a full account of every aspect of the reign of Hsüan-tsung. Also interesting on the politics of the same period is P.A. HERBERT, *Under the Brilliant Emperor: Imperial Authority in T'ang China as Seen in the Writings of Chang Chiu-ling* (1978). There is no modern full-scale study of the An Lu-shan rebellion itself, but the two principal sources exist in well-annotated translations by HOWARD S. LEVY (ed. and trans.), *Biography of An Lu-shan* (1960); and by ROBERT DES ROTOURS (trans.), *Histoire de Ngan Lou-chan* (1962). There is no satisfactory book-length account of the following period. The rebellions of the 780s are described briefly in DENIS TWITCHETT, "Lu Chih (754–805)," in ARTHUR F. WRIGHT and DENIS TWITCHETT (eds.), *Confucian Personalities* (1962). The mysterious reign of Shun-tsung has not been subjected to a modern analytic study, but the principal source is translated in BERNARD S. SOLOMON (ed. and trans.), *The Veritable Record of the T'ang Emperor Shun-tsung* (1955). There is some account of the subsequent reigns in ARTHUR WALEY, *The Life and Times of Po Chü-i, 772–846 A.D.* (1949), but the historical analysis is somewhat outdated. For the period after 847 even the Chinese primary documentation becomes very thin. The only events that have attracted attention of Western scholars are the rebellions; on these see ROBERT DES ROTOURS, "La Révolte de P'ang Hiun," *T'oung Pao,* 56:229–240 (1970); and HOWARD S. LEVY (ed. and trans.), *Biography of Huang Ch'ao,* 2nd rev. ed. (1961). On the Huang Ch'ao rebellion and the subsequent disorders the best account is GUNGWU WANG, *The Structure of Power in North China During the Five Dynasties* (1963, reissued 1967). A number of important studies on T'ang political history, taking account of modern Japanese and Chinese scholarship, are included in ARTHUR F. WRIGHT and DENIS TWITCHETT (eds.), *Perspectives on the T'ang* (1973). JOHN CURTIS PERRY and BARDWELL L. SMITH (eds.), *Essays on T'ang Society: The Interplay of Social, Political, and Economic Forces* (1976), is also a significant collection. On T'ang institutions in general there is a perceptive though outdated (the book was actually completed in 1951) account in HENRI MASPERO and ÉTIENNE BALAZS, *Histoire et institutions de la Chine ancienne,* pp. 160–262 (1967). The traditional sources on the administrative system are translated by ROBERT DES ROTOURS, *Traité des fonctionnaires, et Traité de l'armée,* 2 vol., 2nd rev. ed. (1974), and on the examination system in his *Traité des examens,* 2nd rev. ed. (1976). On finances and general economic problems, see DENIS TWITCHETT, *Financial Administration Under the T'ang Dynasty,* 2nd ed. (1970), which contains a full bibliography. On finance under the Sui, see ÉTIENNE BALAZS, *Études sur la société et l'économie de la Chine médiévale,* 2 vol. (1953–54). For translations of the main documents on T'ang law, see KARL BÜNGER, *Quellen zur Rechtsgeschichte der T'ang-Zeit* (1946); and WALLACE JOHNSON (trans.), *The T'ang Code,* vol. 1 (1979). On general social history, see DENIS TWITCHETT, *Land Tenure and the Social Order in T'ang and Sung China* (1962), "The T'ang Market System," *Asia Major,* 12:202–248 (1966), "Merchant, Trade and Government in Late T'ang," *Asia Major,* 14:63–95 (1968), and *Birth of the Chinese Meritocracy: Bureaucrats and Examinations in T'ang China* (1976); also see the relevant sections of ÉTIENNE BALAZS, *Chinese Civilization and Bureaucracy,* trans. from the French (1964, reprinted 1972). More information is to be found in ROBERT M. HARTWELL, "Demographic, Political, and Social Transformations of China, 750–1550," *Harvard Journal of Asiatic Studies,* 42:365–442 (December 1982); and in the eyewitness account by a contemporary Japanese monk in EDWIN O. REISCHAUER (trans.), *Ennin's Diary* (1955), with a companion volume, *Ennin's Travels in T'ang China* (1955). See also, on the very important evidence from Tun-huang, LIONEL GILES, *Six Centuries of Tunhuang* (1944); and DENIS TWITCHETT, "Chinese Social History from the Seventh to the Tenth Centuries: The Tunhuang Documents and Their Implications," *Past and Present,* 35:28–53 (1966). The following are extremely important for the light they throw on the cosmopolitan nature of T'ang society: EDWARD H. SCHAFER, *The Vermilion Bird: T'ang Images of the South* (1967), *The Golden Peaches of Samarkand: A Study of T'ang Exotics* (1963, reprinted 1985), and *Shore of Pearls* (1970), dealing with the early history of Hai-nan Island. The best general account of Chinese relations with its northern neighbours in the steppes is RENE GROUSSET, *The Empire of the Steppes* (1970; originally published in French, 1939; 4th French ed., 1960). On Chinese overseas trade and relations with Southeast Asia, see GUNGWU WANG, *The Nanhai Trade: A Study of the Early History of Chinese Trade in the South China Sea* (1958). (D.C.T.)

Five Dynasties, Ten Kingdoms, and Sung periods: EDWARD H. SCHAFER, *The Empire of Min* (1954), has the best sinological summary on this kingdom in the South. On conquest dynasties in the North, see HOK-LAM CHAN, *The Historiography of the Chin Dynasty: Three Studies* (1970), his *Legitimation in Imperial China: Discussions Under the Jurchen-Chin Dynasty, 1115–1234* (1984); and JING-SHEN TAO, *The Jurchen in Twelfth-Century China: A Study of Sinicization* (1976). On the Sung period, listings of works in Western languages are available in YVES HERVOUET, *Bibliographie des travaux en langues occidentales sur les Song parus de 1946 à 1965* (1969). Sequels to it appear in various volumes of *Sung Studies Newsletter* (ceased publication in 1978), and its successor, the *Bulletin of Sung and Yüan Studies* (annual). C.P. FITZGERALD, "The Chinese Middle Ages in Communist Historiography," in ALBERT FEUERWERKER (ed.), *History in Communist China* (1968), provides information on some earlier work done by historians in mainland China. On the significance of the Sung and varying interpretations, see JAMES T.C. LIU and PETER J. GOLAS (eds.), *Change in Sung China: Innovation or Renovation?* (1969). Further general information is available in the following: EDWARD A. KRACKE, JR., *Civil Service in Early Sung China, 960–1067* (1953), a monumental work; JAMES T.C. LIU, *Ou-yang Hsiu, an Eleventh-Century Neo-Confucianist,* trans. from the Chinese (1967), and *Reform in Sung China: Wang An-shih (1021–1086) and His New Policies* (1959), both works attempting to relate general trends through historical figures; and BRIAN E. MCKNIGHT, *Village and Bureaucracy in Southern Sung China* (1971), an account coming down to the later period as well as the local scene. JACQUES GERNET, *Daily Life in China on the Eve of the Mongol Invasion, 1250–1276* (1962; originally published in French, 1959), provides vivid descriptions. See also PATRICIA BUCKLEY EBREY (ed. and trans.), *Family and Property in Sung China: Yüan Ts'ai's Precepts for Social Life* (1984), an excellent picture of family relations as studied in the 12th-century work by Yüan Ts'ai; THOMAS H.S. LEE, *Government Education and Examinations in Sung China* (1985), a description of education and its relationship to the civil service; and BRIAN E. MCKNIGHT (trans.), *The Washing Away of Wrongs: Forensic Medicine in Thirteenth-Century China* (1985), a translation of an early work on the topic. (J.T.C.L./B.E.McK.)

The Yüan dynasty: The standard Chinese source is the official dynastic history, *Yüan shih,* completed in 1370. Supplementing this, for the history of Genghis Khan and Ögödei Khan, is the Chinese rendition of the Mongolian historical literary narrative, *Yüan ch'ao pi shih.* It is known in the West through several translations, such as *The Secret History of the Mongols,* trans. by FRANCIS WOODMAN CLEAVES (1982); or *The Secret History of the Mongols,* adapted by PAUL KAHN (1984). A partial listing of Western works on Yüan history is available in HENRY G. SCHWARZ, *Bibliotheca Mongolica: Works in English, French, and German* (1978). On the Mongol operations against China, see the early work of H. DESMOND MARTIN, *The Rise of Chingis Khan and His Conquest of North China* (1950, reissued 1971), now partially superseded by IGOR DE RACHEWILTZ, "Personnel and Personalities in North China in the Early Mongol Period," *Journal of the Economic and Social History of the Orient,* 9:88–144 (1966), a study of the Mongol conquest. On the political history of the later Yüan, see JOHN W. DARDESS, *Conquerors and Confucians: Aspects of Political Change in Late Yüan China* (1973). For works on governmental institutions and legal and military systems, see PAUL RATCHNEVSKY (ed.), *Un Code des Yuan,* 2 vol. (1937–72); FRANZ SCHURMAN (ed. and trans.), *Economic Structure of the Yüan Dynasty* (1956, reissued 1967); HOK-LAM CHAN, "Liu Ping-chung (1216–74): A Buddhist-Taoist Statesman at the Court of Khubilai Khan," *T'oung Pao,* 53:98–146 (1967); HERBERT FRANKE, *From Tribal Chieftain to Universal Emperor and God: The Legitimation of the Yüan Dynasty* (1978); CH'I-CH'ING HSIAO, *The Military Establishment of the Yüan Dynasty* (1978); PAUL HENG-CHAO CH'EN, *Chinese Legal Tradition Under the Mongols: The Code of 1291 as Reconstructed* (1979); and JOHN D. LANGLOIS, JR. (ed.), *China Under Mongol Rule* (1981). For religious and intellectual life of the period, see ARTHUR WALEY (trans.), *The Travels of an Alchemist* (1931, reprinted 1963), on Ch'ang-ch'un; FREDERICK W. MOTE, "Confucian Eremitism in the Yüan period," in ARTHUR F. WRIGHT, *The Confucian Persuasion* (1960); CH'EN YUAN, *Western and Central Asians in China Under the Mongols* (1966), an annotated translation of an authoritative Chinese work; WM.

THEODORE DE BARY, "The Rise of Neo-Confucian Orthodoxy in Yüan China," in his *Neo-Confucian Orthodoxy and the Learning of the Mind-and-Heart* (1981); and HOK-LAM CHAN and WM. THEODORE DE BARY (eds.), *Yüan Thought: Chinese Thought and Religion Under the Mongols* (1982). For works on art and literature of the Yüan dynasty, see SHERMAN E. LEE and WAI-KAM HO, *Chinese Art Under the Mongols: The Yüan Dynasty, 1279–1368* (1968); WAYNE SCHLEPP, *San-ch'ü: Its Technique and Imagery* (1970); CHUNG-WEN SHIH, *The Golden Age of Chinese Drama: Yüan Tsa-chü* (1976); JAMES CAHILL, *Hills Beyond a River: Chinese Painting of the Yüan Dynasty, 1279–1368* (1976); RICHARD JOHN LYNN, *Kuan Yün-shih* (1980), a biography of the poet; and J.I. CRUMP, *Chinese Theater in the Days of Khublai Khan* (1980), and *Songs from Xanadu: Studies in Mongol-Dynasty Song-Poetry (San-ch'u)* (1983). On Chinese contacts with Asia and the West, see E. BRETSCHNEIDER, *Mediaeval Research from Eastern Asiatic Sources: Fragments Towards the Knowledge of the Geography and History of Central and Western Asia from the 13th to the 17th Century*, 2 vol. (1888, reprinted 1967); HERBERT FRANKE, "Sino-Western Contacts Under the Mongol Empire," *Journal of the Hong Kong Branch of the Royal Asiatic Society*, 6:49–72 (1966); LEONARD OLSCHKI, *Marco Polo's Asia: An Introduction to His "Description of the World" called "Il Milione"* (1960; originally published in Italian, 1957); and IGOR DE RACHEWILTZ, *Papal Envoys to the Great Khans* (1971). (H.Fr./H.Ch.)

Ming dynasty: The standard reference guide to traditional Chinese-language materials is WOLFGANG FRANKE, *An Introduction to the Sources of Ming History* (1968). Essential information is contained in L. CARRINGTON GOODRICH and CHAO-YING FANG (eds.), *Dictionary of Ming Biography* (1976). Reviews and articles regularly appear in the journal *Ming Studies* (semiannual). ALBERT CHAN, *The Glory and Fall of the Ming Dynasty* (1982), is a book-length survey of the whole period, but it does not make use of recent critical scholarship. The early Ming years are described and analyzed in EDWARD L. DREYER, *Early Ming China: A Political History, 1355–1435* (1982); and CHARLES O. HUCKER, *The Ming Dynasty: Its Origins and Evolving Institutions* (1978). Additional light is shed on early Ming life, thought, and institutions in EDWARD L. FARMER, *Early Ming Government: The Evolution of Dual Capitals* (1976); FREDERICK W. MOTE, *The Poet Kao Ch'i* (1962); and JOHN W. DARDESS, *Confucianism and Autocracy: Professional Elites in the Founding of the Ming Dynasty* (1983). Early Ming overseas expeditions and foreign relations are dealt with in J.J.L. DUYVENDAK, *China's Discovery of Africa* (1949); and YI-T'UNG WANG, *Official Relations Between China and Japan, 1368–1549* (1953). Specialized studies of mature Ming include CHARLES O. HUCKER, *The Traditional Chinese State in Ming, 1368–1644* (1961), *The Censorial System of Ming China* (1966), and CHARLES O. HUCKER (ed.), *Chinese Government in Ming Times: Seven Studies* (1969); RAY HUANG, *Taxation and Governmental Finance in Sixteenth-Century Ming China* (1974); KWAN-WAI SO, *Japanese Piracy in Ming China During the 16th Century* (1975); PING-TI HO, *Studies on the Population of China, 1368–1953* (1959, reprinted 1967), and *The Ladder of Success in Imperial China: Aspects of Social Mobility, 1368–1911* (1962, reprinted 1976); and AYAO HOSHI *The Ming Tribute Grain System*, trans. from the Chinese by MARK ELVIN (1969). RAY HUANG, *1587, A Year of No Significance: The Ming Dynasty in Decline* (1981), is a wide-ranging critical discussion of Ming governance and the ruling class; a somewhat more approving view of Ming China of the same period is *China in the Sixteenth Century: The Journals of Matthew Ricci, 1583–1610*, trans. from the Latin by LOUIS J. GALLAGHER (1953). Modern studies of China's contacts with Europeans in Ming times notably include T'IEN-TSE CHANG, *Sino-Portuguese Trade from 1514 to 1644* (1934, reprinted 1973); CHARLES R. BOXER (ed. and trans.), *South China in the Sixteenth Century* (1953, reprinted 1967); and GEORGE H. DUNNE, *Generations of Giants: The Story of the Jesuits in China in the Last Decades of the Ming Dynasty* (1962). The last Ming years and the struggles of post-Ming loyalists are dealt with in JAMES B. PARSONS, *The Peasant Rebellions of the Late Ming Dynasty* (1970); LYNN A. STRUVE, *The Southern Ming, 1644–1662* (1984); and JONATHAN D. SPENCE and JOHN E. WILLS, JR. (eds.), *From Ming to Ch'ing: Conquest, Region, and Continuity in Seventeenth-Century China* (1979). Studies in Ming intellectual and religious history are found in WM. THEODORE DE BARY *et al.*, *Self and Society in Ming Thought* (1970), and *The Unfolding of Neo-Confucianism* (1975).

(C.O.Hu.)

The Ch'ing period: (*The rise of the Ch'ing dynasty*): IMMANUEL C.Y. HSU, *The Rise of Modern China*, 3rd ed. (1983); ROBERT H.G. LEE, *The Manchurian Frontier in Ch'ing History* (1970); SILAS H.L. WU, *Communication and Imperial Control in China: Evolution of the Palace Memorial System, 1693–1735* (1970); and FREDERIC WAKEMAN, JR., *The Great Enterprise: The Manchu Reconstruction of the Imperial Order in Seventeenth-Century China* (1985). (*Early foreign relations*): LUCIANO PETECH, *China and Tibet in the Early 18th Century*, 2nd rev. ed. (1972); CHUSEI SUZUKI, "China's Relations with Inner Asia: The Hsiung-nu, Tibet," pp. 180–197 in JOHN K. FAIRBANK (ed.), *The Chinese World Order* (1968); EARL H. PRITCHARD, *Anglo-Chinese Relations During the Seventeenth and Eighteenth Centuries* (1929, reissued 1970), and *The Crucial Years of Early Anglo-Chinese Relations, 1750–1800* (1936, reissued 1970); ANTONIO S. ROSSO, *Apostolic Legations to China of the Eighteenth Century* (1948); and MARC MANCALL, *Russia and China: Their Diplomatic Relations to 1728* (1971). (*Mid-Ch'ing society and economy*): CHUNG-LI CHANG, *The Chinese Gentry* (1955, reprinted 1974); T'UNG-TSU CHU, *Local Government in China Under the Ch'ing* (1962, reissued 1969); MADELEINE ZELIN, *The Magistrate's Tael: Rationalizing Fiscal Reform in Eighteenth-Century Ch'ing China* (1984); and YEH-CHIEN WANG, *Land Taxation in Imperial China, 1750–1911* (1973). (*Intellectual and cultural aspects*): L. CARRINGTON GOODRICH, *The Literary Inquisition of Ch'ien-lung*, 2nd ed. (1966); JOSEPH R. LEVENSON, *Confucian China and Its Modern Fate*, 3 vol. (1958–65, reissued in 1 vol., 1968), and "The Abortiveness of Empiricism in Early Ch'ing Thought," *Far Eastern Quarterly*, 13:155–165 (1954); CH'I-CH'AO LIANG, *Intellectual Trends in the Ch'ing Period*, trans. by IMMANUEL C.Y. HSU (1959); and EVELYN SAKAKIDA RAWSKI, *Education and Popular Literacy in Ch'ing China* (1979). (*Dynastic degeneration*): JEAN CHESNEAUX (comp.), *Secret Societies in China in the Nineteenth and Twentieth Centuries* (1971; originally published in French, 1965); KUNG-CHUAN HSIAO, *Rural China: Imperial Control in the Nineteenth Century* (1960, reprinted 1967); GILBERT ROZMAN (ed.), *The Modernization of China* (1981), an interdisciplinary study of China's modernization between the Opium Wars and 1980; PHILIP A. KUHN, *Rebellion and Its Enemies in Late Imperial China: Militarization and Social Structure, 1794–1864* (1970, reprinted 1980); and SUSAN NAQUIN, *Millenarian Rebellion in China: The Eight Trigrams Uprising of 1813* (1976). (*Western challenges*): MASATAKA BANNO, *China and the West, 1858–1861: The Origins of the Tsungli Yamen* (1964); HSIN-PAO CHANG, *Commissioner Lin and the Opium War* (1964, reprinted 1970); W.C. COSTIN, *Great Britain and China, 1833–1860* (1937, reprinted 1968); JOHN K. FAIRBANK, *Trade and Diplomacy on the China Coast*, 2 vol. (1953, reissued in 1 vol., 1969); MICHAEL GREENBERG, *British Trade and the Opening of China, 1800–42* (1951, reprinted 1979); IMMANUEL C.Y. HSU, *China's Entrance into the Family of Nations: The Diplomatic Phase, 1858–1880* (1960); and PETER WARD FAY, *The Opium War, 1840–1842* (1975).

(*The Taipings*): VINCENT Y.C. SHIH, *The Taiping Ideology: Its Sources, Interpretations, and Influences* (1967, reprinted 1972); FRANZ H. MICHAEL and CHANG CHUNG-LI, *The Taiping Rebellion: History and Documents*, 3 vol. (1966–71); and ALBERT FEUERWERKER, *Rebellion in Nineteenth-Century China* (1975). (*Nien Rebellion*): SIANG-TSEH CHIANG, *The Nien Rebellion* (1954, reprinted 1967); S.Y. TENG, *The Nien Army and Their Guerrilla Warfare, 1851–1868* (1961, reprinted 1984); and ELIZABETH J. PERRY, *Rebels and Revolutionaries in North China, 1845–1945* (1980). (*Chinese response*): ALBERT FEUERWERKER, *China's Early Industrialization: Sheng Hsüan-huai (1844–1916) and Mandarin Enterprise* (1958, reissued 1970); YEN-P'ING HAO, *The Comprador in Nineteenth Century China: Bridge Between East and West* (1970); PAUL A. COHEN, *Between Tradition and Modernity: Wang T'ao and Reform in Late Ch'ing China* (1974); WILLIAM T. ROWE, *Hankow: Commerce and Society in a Chinese City, 1796–1889* (1984); LUKE S.K. KWONG, *A Mosaic of the Hundred Days: Personalities, Politics, and Ideas of 1898* (1984); and KUNG-CH'UAN HSIAO, *A Modern China and a New World: K'ang Yu-wei, Reformer and Utopian, 1858–1927* (1975). (*Boxer Rebellion*): PAUL A. COHEN, *China and Christianity: The Missionary Movement and the Growth of Chinese Antiforeignism, 1860–1870* (1963); and VICTOR PURCELL, *The Boxer Uprising* (1963, reprinted 1974).

For a comprehensive survey of the development of state power, see JOHN K. FAIRBANK, *The Great Chinese Revolution, 1800–1985* (1986). (*Revolutionary movements at the end of the Ch'ing*): MICHAEL GASSTER, *Chinese Intellectuals and the Revolution of 1911: The Birth of Modern Chinese Radicalism* (1969); ROBERT A. SCALAPINO and GEORGE T. YU, *The Chinese Anarchist Movement* (1961, reprinted 1980); HAROLD Z. SCHIFFRIN, *Sun Yat-sen and the Origins of the Chinese Revolution* (1968); JOHN H. FINCHER, *Chinese Democracy, the Self-Government Movement in Local, Provincial, and National Politics, 1905–1914* (1981); MARY B. RANKIN, *Early Chinese Revolutionaries: Radical Intellectuals in Shanghai and Chekiang, 1902–1911* (1971); EDWARD J.M. RHOADS, *China's Republican Revolution: The Case of Kwangtung, 1895–1913* (1975); JOSEPH W. ESHERICK, *Reform and Revolution in China: The 1911 Revolution in Hunan and Hubei* (1976); and EDMUND S.K. FUNG, *The Military*

Dimension of the Chinese Revolution: The New Army and Its Role in the Revolution of 1911 (1980). (C.Su./A.Fe.)

Twentieth-century China: (Republican China): An accomplished text on this period is JAMES E. SHERIDAN, *China in Disintegration: The Republican Era in Chinese History, 1912–1949* (1975); more detailed and politically centred is O. EDMUND CLUBB, *20th Century China*, 3rd ed. (1978). There are two excellent collections of biographies of the leading figures of the period: HOWARD L. BOORMAN and RICHARD C. HOWARD (eds.), *Biographical Dictionary of Republican China*, 5 vol. (1967–79); and DONALD W. KLEIN and ANNE B. CLARKE, *Biographic Dictionary of Chinese Communism, 1921–65*, 2 vol. (1971). For the revolution of 1911–12 and the early republican period, scholarly essays offering fresh interpretations are found in MARY C. WRIGHT (ed.), *China in Revolution: The First Phase, 1900–1913* (1968). The immediate consequences of the revolution of 1911–12 and the search for an appropriate political form for China are analyzed in EDWARD FRIEDMAN, *Backward Toward Revolution: The Chinese Revolutionary Party* (1974, reprinted 1977); and ERNEST P. YOUNG, *The Presidency of Yuan Shih-K'ai: Liberalism and Dictatorship in Early Republican China* (1977). The dimensions of the ebullient intellectual and political movements in China in the late teens are still best presented in a classic work, TSE-TUNG CHOW, *The May Fourth Movement: Intellectual Revolution in Modern China* (1960, reissued 1967). For a more critical view of some of the leading participants, see YÜ-SHENG LIN, *The Crisis of Chinese Consciousness: Radical Antitraditionalism in the May Fourth Era* (1979).

The period of warlordism has been comprehensively treated by HSI-SHENG CH'I, *Warlord Politics in China, 1916–1928* (1976). Among studies of particular warlord formations, especially notable are JAMES E. SHERIDAN, *Chinese Warlord: The Career of Feng Yü-hsiang* (1966); and DONALD E. SUTTON, *Provincial Militarism and the Chinese Republic: The Yunnan Army, 1905–25* (1980). Economic conditions are discussed in R.H. TAWNEY'S prophetic and still valuable study, *Land and Labour in China* (1932, reprinted 1966). Essays in DWIGHT H. PERKINS (ed.), *China's Modern Economy in Historical Perspective* (1975), are relevant. A penetrating analysis of a critical sector of China's rural social order is PHILIP C.C. HUANG, *The Peasant Economy and Social Change in North China* (1985). On the Nationalist revolution, see C. MARTIN WILBUR and JULIE LIEN-YING HOW (eds.), *Documents on Communism, Nationalism, and Soviet Advisers in China, 1918–1927* (1956, reissued with corrections, 1972). The struggles that displaced warlords from centre stage are set forth in C. MARTIN WILBUR, *The Nationalist Revolution in China, 1923–1928* (1984). RICHARD W. RIGBY, *The May 30 Movement: Events and Themes* (1980), is a study of one of the most energizing of these struggles. The new national government that emerged has been brilliantly portrayed in LLOYD E. EASTMAN, *The Abortive Revolution: China Under Nationalist Rule, 1927–1937* (1974). Among the interesting rebuttals to some of Eastman's arguments is JOSEPH FEWSMITH, *Party, State, and Local Elites in Republican China: Merchant Organizations and Politics in Shanghai, 1890–1930* (1985).

Events of the war with Japan are discussed in HSI-SHENG CH'I, *Nationalist China at War: Military Defeats and Political Collapse, 1937–45* (1982); and LLOYD E. EASTMAN, *Seeds of Destruction: Nationalist China in War and Revolution, 1937–1949* (1984). Works dealing with wartime conditions in Nationalist areas are CHIA-AO CHANG, *The Inflationary Spiral: The Experience in China, 1939–1950* (1958); and CHARLES F. ROMANUS and RILEY SUNDERLAND, *The United States Army in World War II: China–Burma–India Theatre*, 3 vol. (1952–58), which is carefully documented and well illustrated.

(Communist China): The emergence and growth of the Communist opposition to Nationalist rule can be traced in BENJAMIN I. SCHWARTZ, *Chinese Communism and the Rise of Mao* (1951, reprinted 1979); JOHN E. RUE, *Mao Tse-tung in Opposition, 1927–1935* (1966); JEROME CH'EN, *Mao and the Chinese Revolution* (1965); STUART R. SCHRAM, *Mao Tse-tung* (1967); TRYGVE LÖTVEIT, *Chinese Communism 1931–1934: Experience in Civil Government*, 2nd ed. (1979); and MARK SELDEN, *The Yenan Way in Revolutionary China* (1971). The broadest work treating the history of the Communist movement is CONRAD BRANDT, BENJAMIN I. SCHWARTZ, and JOHN K. FAIRBANK, *A Documentary History of Chinese Communism* (1952, reprinted 1966). A stimulating reportorial work is EDGAR SNOW, *Red Star over China*, rev. ed. (1968, reprinted 1973); while a broad survey is presented by LYMAN P. VAN SLYKE, *Enemies and Friends: The United Front in Chinese Communist History* (1967). The particular role of women and the consequences of the limits placed on their full participation have been the topic of DELIA DAVIN, *Woman-Work: Women and the Party in Revolutionary China* (1976); and JUDITH STACEY, *Patriarchy and Socialist Revolution in China* (1983). The final phase of contest between the two parties is interpreted in SUSANNE PEPPER, *Civil War in China: The Political Struggle, 1945–1949* (1978).

On China's relations with foreign powers, see AKIRA IRIYE, *After Imperialism: The Search for a New Order in the Far East, 1921–1931* (1965, reprinted 1978). O. EDMUND CLUBB, *China and Russia: The "Great Game"* (1971), is a general work on Sino-Soviet relations; while a fine study of American policy toward China during a limited period between the world wars is given in DOROTHY BORG, *The United States and the Far Eastern Crisis of 1933–1938* (1964). See also MICHAEL SCHALLER, *The U.S. Crusade in China, 1938–1945* (1979); and DOROTHY BORG and WALDO HEINRICHS (eds.), *Uncertain Years: Chinese-American Relations, 1947–1950* (1980). F.C. JONES, *Japan's New Order in Asia: Its Rise and Fall, 1937–45* (1954, reprinted 1978); and F.F. LIU, *A Military History of Modern China, 1924–1949* (1956, reprinted 1981), provide information on the military aspects of Sino-Japanese relations. Also see AKIRA IRIYE (ed.), *The Chinese and the Japanese: Essays in Political and Cultural Interactions* (1980). A scholarly study of foreign assistance to China during the Sino-Japanese War is ARTHUR N. YOUNG, *China and the Helping Hand, 1937–1945* (1963). JONATHAN R. ADELMAN, *The Revolutionary Armies: The Historical Development of the Soviet and Chinese People's Liberation Armies* (1980), is a comparative study. Other treatments include WILLIAM C. KIRBY, *Germany and Republican China* (1984); and JAMES REARDON-ANDERSON, *Yenan and the Great Powers: The Origins of Chinese Communist Foreign Policy, 1944–1946* (1980).

For developments in the Communist regions during the Sino-Japanese War, in addition to the general works on the Communist movement cited above, see LYMAN P. VAN SLYKE (ed.), *The Chinese Communist Movement: A Report of the United States War Department, July 1945* (1968), a close factual account based on intelligence studies. CHALMERS A. JOHNSON, *Peasant Nationalism and Communist Power: The Emergence of Revolutionary China* (1962), provides a scholarly interpretation of Communist successes behind Japanese lines. The final civil war period is covered by LIONEL MAX CHASSIN, *The Communist Conquest of China: A History of the Civil War, 1945–1949* (1965; originally published in French, 1952).

The most influential work of Sun Yat-sen has been translated under the title *San Min Chu I: The Three Principles of the People*, trans. by FRANK W. PRICE (1927). The most revealing work of Chiang Kai-shek is his *China's Destiny and Chinese Economic Theory*, published in English with comments by PHILIP JAFFE (1947). The official translation of Mao Zedong's (Mao Tse-tung's) *Selected Works*, 4 vol., is that published by the Foreign Languages Press, Peking (1961–65). STUART R. SCHRAM, *The Political Thought of Mao Tse-tung*, rev. ed. (1969), is the best introduction to Chinese Communist ideology.

The bibliography on contemporary Chinese history is vast and growing rapidly. Although publications on modern China are uneven in coverage and quality, most subjects of interest have been discussed in the writings of scholars and visitors to China and Taiwan. A comprehensive bibliography of these writings is compiled annually by the *Journal of Asian Studies*. See also GEORGE GINSBURGS and MICHAEL MATHOS, *Communist China and Tibet: The First Dozen Years* (1964); EDGAR SNOW, *Red China Today* (1971); JOHN WILSON LEWIS, *Leadership in Communist China* (1963, reprinted 1978), and (ed.), *The City in Communist China* (1971); BENJAMIN I. SCHWARTZ, *Communism and China: Ideology in Flux* (1968); C.K. YANG, *The Chinese Communist Society: The Family and the Village* (1965); BYUNG-JOON AHN, *Chinese Politics and the Cultural Revolution: Dynamics of Policy Processes* (1976); LOWELL DITTMER, *Liu Shao-Ch'i and the Chinese Cultural Revolution: The Politics of Mass Criticism* (1974); KENNETH LIEBERTHAL, *Revolution and Tradition in Tientsin, 1949–1952* (1980); MAURICE MIESNER, *Mao's China: History of the People's Republic* (1977); WILLIAM E. GRIFFITH, *The Sino-Soviet Rift, Analysed and Documented* (1964), and *Sino-Soviet Relations, 1964–1965* (1967); RICHARD BAUM, *Prelude to Revolution: Mao, the Party, and the Peasant Question, 1962–66* (1975); RODERICK MACFARQUHAR, *The Origins of the Cultural Revolution*, 2 vol. (1974–83); FREDERICK C. TEIWES, *Politics and Purges in China: Rectifications and the Decline of Party Norms, 1950–1965* (1979); TANG TSOU, *The Cultural Revolution and Post-Mao Reforms* (1986); EDWARD E. RICE, *Mao's Way* (1972); ROBERT A. SCALAPINO (ed.), *Elites in the People's Republic of China* (1972); STUART SCHRAM (ed.), *Mao Tse-tung Unrehearsed: Talks and Letters: 1956–71* (1974, U.S. title, *Chairman Mao Talks to the People: Talks and Letters, 1956–1971*); FREDERIC WAKEMAN, JR., *History and Will: Philosophical Perspectives of Mao Tse-tung's Thought* (1973); WILLIAM W. WHITSON and CHEN-HSIA HUANG, *The Chinese High Command: A History of Communist Military Politics, 1927–71* (1973); MARTIN KING WHYTE, *Small Groups and Political Rituals in China* (1974); MARGERY WOLF and ROXANE WITKE (eds.), *Women in Chinese Society* (1975); and MARGERY WOLF, *Revolution Postponed: Women in Contemporary China* (1985).

(C.M.Wi./E.P.Y./K.G.L.)

Provinces. *General works:* For the study of provinces, two map collections are helpful: UNITED STATES. CENTRAL INTELLIGENCE AGENCY, *Communist China Map Folio* (1967), and *Communist China Administrative Atlas* (1969). In addition to materials listed in the geographical section at the beginning of this bibliography, the following studies contain information on the provinces: CHIAO-MIN HSIEH, *China: Ageless Land and Countless People* (1967); LEO J. MOSER, *The Chinese Mosaic: The Peoples and Provinces of China* (1985); GEORGE BABCOCK CRESSEY, *Asia's Lands and Peoples,* 3rd ed. (1963); YI-FU TUAN, *China* (1969); ALBERT HERRMANN, *An Historical Atlas of China,* new ed. (1966); AUREL STEIN, *Innermost Asia,* 5 vol. (1928, reprinted 1981); PING-HAI CHU, *Climate of China,* trans. from the Chinese (1967); JAMES S. LEE, *The Geology of China* (1939); UNITED STATES DEPARTMENT OF THE INTERIOR, *Foreign Minerals Survey: Regional Review,* vol. 2, *Mineral Resources of China* (1948); RONALD HSIA, *Steel in China* (1971); YUAN-LI WU, *The Steel Industry in Communist China* (1965); FREDERICK C. TEIWES, *Provincial Leadership in China: The Cultural Revolution and Its Aftermath* (1974); PARRIS H. CHANG, *Power and Policy in China,* 2nd ed. (1978); and CH'ANG-TU HU, *The Education of National Minorities in Communist China* (1970).

Northeast and North China: WASHINGTON (STATE) UNIVERSITY, FAR EASTERN AND RUSSIAN INSTITUTE, *A Regional Handbook on Northeast China* (1956); NAI-RUENN CHEN, *Chinese Economic Statistics: A Handbook for Mainland China* (1967); and DONALD G. GILLIN, *Warlord: Yen Hsi-shan in Shansi Province, 1911–1949* (1967).

Lower Yangtze Valley: CHING-CHIH SUN (ed.), *Economic Geography of Central China* (1960), and *Economic Geography of the East China Region* (1961); JONATHAN K. OCKO, *Bureaucratic Reform in Provincial China: Ting Jih-Ch'ang in Restoration Kiangsu, 1867–1870* (1983); ANDREA LEE MCELDERRY, *Shanghai Old-Style Banks (ch'ien-chuang), 1800–1935: A Traditional Institution in a Changing Society* (1976); PARKS M. COBLE, JR., *The Shanghai Capitalists and the Nationalist Government, 1927–1937* (1980); NICHOLAS R. CLIFFORD, *Shanghai, 1925: Urban Nationalism and the Defense of Foreign Privilege* (1979); and "Hubei, Anatomy of a Province," *China Business Review,* 7(5):39–47 (September–October 1980).

South China: R. KEITH SCHOPPA, *Chinese Elites and Political Change: Zhejiang Province in the Early Twentieth Century* (1982); KEITH FORSTER, "The Reform of Provincial Party Committees in China: The Case of Zhejiang," *Asian Survey,* 24:618–636 (June 1984); MICHEL OKSENBERG and SAI-CHEUNG YEUNG, "Hua Kuo-feng's Pre-Cultural Revolution Hunan Years, 1949–66," *China Quarterly,* 69:3–53 (March 1977); REWI ALLEY, *Land and Folk in Kiangsi: A Chinese Province in 1961* (1962); DIANA LARY, *Religion and Nation: The Kwangsi Clique in Chinese Politics, 1925–1937* (1974); and EZRA F. VOGEL, *Canton Under Communism: Programs and Politics in a Provincial Capital, 1949–1968* (1969, reprinted 1980).

Southwest China: HAN-SHENG CH'EN, *Frontier Land Systems in Southernmost China* (1949); ERNEST HENRY WILSON, *A Naturalist in Western China,* 2 vol. (1913, reprinted 1977); DOROTHY J. SOLINGER, *Regional Government and Political Integration in Southwest China, 1949–1954: A Case Study* (1977); HENRY R. DAVIES, *Yunnan, the Link Between India and the Yangtze* (1909, reissued 1970); and ROBERT A. KAPP, *Szechwan and the Chinese Republic: Provincial Militarism and Central Power, 1911–1938* (1973).

Western China: JACK CHEN, *The Sinkiang Story* (1977); DONALD H. MCMILLEN, *Chinese Communist Power and Policy in Xinjiang, 1949–1977* (1979); COLIN MACKERRAS, "Uygur Performing Arts in Contemporary China," *China Quarterly,* 101:58–77 (March 1985); CHARLES BELL, *Tibet Past and Present* (1924, reprinted 1968); TIEH-TSENG LI, *Tibet, Today and Yesterday,* rev. ed. (1960); W.D. SHAKABPA, *Tibet, a Political History* (1967, reissued 1984); DAVID SNELLGROVE and HUGH RICHARDSON, *A Cultural History of Tibet,* rev. ed. (1980); ALASTAIR LAMB, *Britain and Chinese Central Asia: The Road to Lhasa, 1767 to 1905* (1960); GEORGE GINSBURGS and MICHAEL MATHOS, *Communist China and Tibet* (1964); DALAI LAMA (XIV) OF TIBET, *My Land and My People* (1962, reissued 1977); SARAT CHANDRA DAS, *Journey to Lhasa and Central Tibet* (1902, reissued 1970); HUGH RICHARDSON, *Tibet and Its History,* 2nd rev. ed. (1984); and JOHN F. AVEDON, *In Exile from the Land of Snows* (1984).

Northwest China: WASHINGTON (STATE) UNIVERSITY. FAR EASTERN AND RUSSIAN INSTITUTE, *A Regional Handbook on Northwest China,* 2 vol. (1956), and *A Regional Handbook on the Inner Mongolia Autonomous Region* (1956); WEN-DJANG CHU, *The Moslem Rebellion in Northwest China, 1862–1878: A Study of Government Minority Policy* (1966); ROBERT J. MILLER, *Monasteries and Culture Change in Inner Mongolia* (1959); OWEN LATTIMORE, *Mongol Journeys* (1941, reprinted 1975), and *Nomads and Commissars: Mongolia Revisited* (1962); and SECHIN JAGCHID and PAUL HYER, *Mongolia's Culture and Society* (1979).

Chinese Literature

Chinese literature is one of the major literary heritages of the world, with an uninterrupted history of more than 3,000 years, dating back at least to the 14th century BC. Its medium, the Chinese language, has retained its unmistakable identity in both its spoken and written aspects in spite of generally gradual changes in pronunciation, the existence of regional and local dialects, and several stages in the structural representation of the written graphs, or "characters." Even the partial or total conquests of China for considerable periods by non-Chinese ethnic groups from outside the Great Wall failed to disrupt this continuity, for the conquerors were forced to adopt the written Chinese language as their official medium of communication because they had none of their own. Since the Chinese graphs were inherently nonphonetic, they were at best unsatisfactory tools for the transcription of a non-Chinese language; and attempts at creating a new alphabetic–phonetic written language for empire building proved unsuccessful on three separate occasions. The result was that after a period of alien domination, the conquerors were culturally assimilated (except the Mongols, who retreated en masse to their original homeland after the collapse of the Yüan [or Mongol] dynasty in 1368). Thus, there was no disruption in China's literary development.

This article is divided into the following sections:

GENERAL CHARACTERISTICS

Through cultural contacts, Chinese literature has profoundly influenced the literary traditions of other Asian countries, particularly Korea, Japan, and Vietnam. Not only was the Chinese script adopted for the written language in these countries but some writers adopted the Chinese language as their chief literary medium.

The graphic nature of the written aspect of the Chinese language has produced a number of noteworthy effects upon Chinese literature and its diffusion: (1) Chinese literature, especially poetry, is recorded in handwriting or in print and purports to make an aesthetic appeal to the reader that is visual as well as aural. (2) This visual appeal of the graphs has in fact given rise to the elevated status of calligraphy in China, where it has been regarded for at least the last 16 centuries as a fine art comparable to painting. Scrolls of calligraphic renderings of poems and prose selections have continued to be hung alongside paintings in the homes of the common people as well as the elite, converting these literary gems into something to be enjoyed in everyday living. (3) On the negative side, such a writing system has been an impediment to education and the spread of literacy, thus reducing the number of readers of literature; for even a rudimentary level of reading and writing requires knowledge of more than 1,000 graphs, together with their pronunciation. (4) On the other hand, the Chinese written language, even with its obvious disadvantages, has been a potent factor in perpetuating the cultural unity of the growing millions of the Chinese people, including assimilated groups in far-flung peripheral areas. Different in function from recording words in an alphabetic–phonetic language, the graphs are not primarily indicators of sounds and can therefore be pronounced in variant ways to accommodate geographical diversities in speech and historical phonological changes without damage to the meaning of the written page. As a result, the major dialects in China never developed into separate written languages as did the Romance languages, and, although the reader of a Confucian Classic in southern China might not understand the everyday speech of someone from the far north, Chinese literature has continued to be the common asset of the whole Chinese people. By the same token, the graphs of China could be utilized by speakers of other languages as their literary mediums.

The pronunciation of the Chinese graphs has also influenced the development of Chinese literature. The fact that each graph had a monophonic pronunciation in a given context created a large number of homonyms, which led to misunderstanding and confusion when spoken or read aloud without the aid of the graphs. One corrective was the introduction of tones or pitches in pronunciation. As a result, metre in Chinese prosody is not concerned with the combination of syllabic stresses, as in English, but with those of syllabic tones, which produce a different but equally pleasing cadence. This tonal feature of the Chinese language has brought about an intimate relationship between poetry and music in China. All major types of Chinese poetry were originally sung to the accompaniment of music. Even after the musical scores were lost, the poems were, as they still are, more often chanted—in order to approximate singing—than merely read.

Relationship between poetry and music

Chinese poetry, besides depending on end rhyme and tonal metre for its cadence, is characterized by its compactness and brevity. There are no epics of either folk or literary variety and hardly any narrative or descriptive poems that are long by the standards of world literature. Stressing the lyrical, as has often been pointed out, the Chinese poet refrains from being exhaustive, marking instead the heights of his ecstasies and inspiration or the depths of sorrow and sympathy. A short poem in Chinese sometimes resembles a cablegram, wherein verbal economy is highly desirable. Generally, pronouns and conjunctions are omitted, and one or two words often allude to highly complex thoughts or situations. This explains why many poems have been differently interpreted by learned commentators and competent translators.

The line of demarcation between prose and poetry is much less distinctly drawn in Chinese literature than in other national literatures. This is clearly reflected in three genres. The *fu*, for example, is on the borderline between poetry and prose, containing elements of both. It uses rhyme and metre and not infrequently also antithetic structure, but, despite occasional flights into the realm of the poetic, it retains the features of prose without being necessarily prosaic. This accounts for the variety of labels given to the *fu* in English by writers on Chinese literature—poetic prose, rhyme prose, prose poem, rhapsody, and prose poetry.

Another genre belonging to this category is *p'ien-wen* ("parallel prose"), characterized by antithetic construction and balanced tonal patterns without the use of rhyme; the term is suggestive of "a team of paired horses," as is implied in the Chinese word *p'ien*. Despite the polyphonic effect thus produced, which approximates that of poetry, it has often been made the vehicle of proselike exposition and argumentation. Another genre, a peculiar mutation in this borderland, is the *pa-ku wen-chang* ("eight-legged essay"). Now generally regarded as unworthy of classification as literature, for centuries (from 1487 to 1901) it dominated the field of Chinese writing as the principal

yardstick in grading candidates in the official civil-service examinations. It exploited antithetical construction and contrasting tonal patterns to the limit by requiring pairs of columns consisting of long paragraphs, one responding to the other, word for word, phrase for phrase, sentence for sentence.

The two kinds of prose

Chinese prose writing has been diverted into two streams, separated at least for the last 1,000 years by a gap much wider than the one between folk songs and so-called literary poems. Classical, or literary, prose (*ku-wen*, or *wen-yen*) aims at the standards and styles set by ancient writers and their distinguished followers of subsequent ages, with the Confucian Classics and the early philosophers as supreme models. While the styles may vary with individual writers, the language is always far removed from their spoken tongues. Sanctioned by official requirement for the competitive examinations and dignified by traditional respect for the cultural accomplishments of past ages, this medium became the linguistic tool of practically all Chinese prose writers. Vernacular prose (*pai-hua*), in contrast, consists of writings in the living tongue, the everyday language of the authors. Traditionally considered inferior, the medium was piously avoided for creative writing until it was adopted by novelists and playwrights from the 13th century on.

HISTORY

Origins: c. 1400–221 BC. The oldest specimens of Chinese writing extant are inscriptions on bones and tortoise shells dating back to the last three centuries of the Shang dynasty (18th–12th centuries BC) and recording divinations performed at the royal capital. These inscriptions, like those engraved on ceremonial bronze vessels toward the end of the Shang period, are usually brief and factual and cannot be considered literature. Nonetheless, they are significant in that their sizable vocabulary (about 3,400 characters, of which nearly 2,000 have been reliably deciphered) has proved to be the direct ancestor of the modern Chinese script. Moreover, the syntactical structure of the language bears a striking resemblance to later usages. From the frequent occurrences in the bone inscriptions of such characters as "dance" and "music," "drum" and "chimes" (of stone), "words" and "southern" (airs), it can safely be inferred that, by the Shang dynasty, songs were sung to the accompaniment of dance and music; but these songs are now lost. (T.-y.L./W.H.N.)

Literary use of myths. Early Chinese literature does not present, as the literatures of certain other world cultures do, great epics embodying mythological lore. What information exists is sketchy and fragmentary and provides no clear evidence that an organic mythology ever existed; if it did, all traces have been lost. Attempts by scholars, Eastern and Western alike, to reconstruct the mythology of antiquity have consequently not advanced beyond probable theses. Shang dynasty material is limited. Chou dynasty (*c.* 1111–255 BC) sources are more plentiful, but even these must at times be supplemented by writings of the Han period (206 BC–AD 220), which, however, must be read with great caution. This is the case because Han scholars reworked the ancient texts to such an extent that no one is quite sure, aside from evident forgeries, how much was deliberately reinterpreted and how much was changed in good faith in an attempt to clarify ambiguities or reconcile contradictions.

The early state of Chinese mythology was also molded by the religious situation that prevailed in China at least since the Chou conquest (12th century BC), when religious observance connected with the cult of the dominant deities was proclaimed a royal prerogative. Because of his temporal position, the king alone was considered qualified to offer sacrifice and to pray to these deities. Shang-ti ("Supreme Ruler"), for example, one of the prime dispensers of change and fate, was inaccessible to persons of lower rank. The princes, the aristocracy, and the commoners were thus compelled, in descending order, to worship lesser gods and ancestors. Though this situation was greatly modified about the time of Confucius in the early part of the 5th century BC, institutional inertia and a trend toward rationalism precluded the revival of a mythological world. Confucius prayed to Heaven (T'ien) and was concerned about the great sacrifices, but he and his school had little use for genuine myths.

Nevertheless, during the latter centuries of the Chou, Chinese mythology began to undergo a profound transformation. The old gods, to a great extent already forgotten, were gradually supplanted by a multitude of new ones, some of whom were imported from India with Buddhism or gained popular acceptance as Taoism spread throughout the empire. In the process, many early myths were totally reinterpreted to the extent that some deities and mythological figures were rationalized into abstract concepts and others were euhemerized into historical figures. Above all, a hierarchical order, resembling in many ways the institutional order of the empire, was imposed upon the world of the supernatural. Many of the archaic myths were lost; others survived only as fragments, and, in effect, an entirely new mythological world was created.

These new gods generally had clearly defined functions and definite personal characteristics and became prominent in literature and the other arts. The myth of the battles between Huang-ti ("The Yellow Emperor") and Ch'ih Yu ("The Wormy Transgressor"), for example, became a part of Taoist lore and eventually provided models for chapters of two works of vernacular fiction, *Shui-hu chuan* (*The Water Margin*, also translated as *All Men Are Brothers*) and *Hsi-yu chi* (1592; *Journey to the West*, also partially translated as *Monkey*). Other mythological figures such as K'ua-fu and the Hsi-wang-mu subsequently provided motifs for numerous poems and stories.

Historical personages were also commonly taken into the pantheon, for Chinese popular imagination has been quick to endow the biography of a beloved hero with legendary and eventually mythological traits. Ch'ü Yüan, the ill-fated minister of the state of Ch'u (771–221 BC), is the most notable example. Mythmaking consequently became a constant, living process in China. It was also true that historical heroes and would-be heroes arranged their biographies in a way that lent themselves to mythologizing. (He.W./W.H.N.)

First anthology of poetry: *Shih Ching*

Poetry. The first anthology of Chinese poetry, known as the *Shih Ching* ("Classic of Poetry") and consisting of temple, court, and folk songs, was given definitive form somewhere around the time of Confucius (551–479 BC). But its 305 songs are believed to range in date from the beginning of the Chou dynasty to the time of their compiling.

The *Shih Ching* is generally accounted the third of the Five Classics (*Wu Ching*) of Confucian literature, the other four of which are: the *I Ching* ("Classic of Changes"), a book of divination and cosmology; the *Shu Ching* ("Classic of History"), a collection of official documents; the *Li chi* ("Record of Rites"), a book of rituals with accompanying anecdotes; and the *Ch'un-ch'iu* ("Spring and Autumn") annals, a chronological history of the feudal state of Lu, where Confucius was born, consisting of topical entries of major events from 722 to 481 BC. The Five Classics have been held in high esteem by Chinese scholars since the 2nd century BC. (For a discussion of the *I Ching* and *Shu Ching*, see below *Prose*.)

The poems of the *Shih Ching* were originally sung to the accompaniment of music; and some of them, especially temple songs, were accompanied also by dancing. (In all subsequent periods of Chinese literary history, new trends in poetry were profoundly influenced by music.) Most of the poems of the *Shih Ching* have a preponderantly lyrical strain whether the subject is hardship in military service or seasonal festivities, agricultural chores or rural scenes, love or sports, aspirations or disappointments of the common folk and of the declining aristocracy. Apparently, the language of the poems was relatively close to the daily speech of the common people, and even repeated attempts at refinement during the long process of transmission have not spoiled their freshness and spontaneity. In spite of this, however, when the songs are read aloud and not sung to music their prevailing four-syllable lines conduce to monotony, hardly redeemed by the occasional interspersion of shorter or longer lines.

If there ever was an epic tradition in ancient China

comparable to that of early India or the West, only dim traces of it persist in the written records. The *Shih Ching* has a few narrative poems celebrating heroic deeds of the royal ancestors, but these are rearranged in cycles and only faintly approximate the national epics of other peoples. One cycle, for example, records the major stages in the rise of the Chou kingdom, from the supernatural birth of its remote founder to its conquest of the Shang kingdom. These episodes, which, according to traditional history, cover a period of more than 1,000 years, are dealt with in only about 400 lines. Other cycles, which celebrate later military exploits of the royal Chou armies, are even briefer.

The *Shih Ching* exerted a profound influence on Chinese poetry that, generally speaking, has stressed the lyrical rather than the narrative element; a dependence more on end rhymes for musical effect than on other rhetorical devices; regular lines, consisting of a standard number of syllables; and the utilization of intonation that is inherent in the language for rhythm, instead of the alternation of stressed and unstressed syllables as is the norm in Western poetry. The high regard in which this anthology has been held in China results both from its antiquity and from the legend that Confucius himself edited it. It was elevated in 136 BC to the position of a major classic in the Confucian canon.

Meanwhile, another type of poetry, also originating in music and dance, had developed in the south, in the basin of the Yangtze River, an area dominated by the principality of Ch'u—hence the generic appellation *Ch'u tz'u,* or "songs of Ch'u." These southern songs, though adorned with end rhymes like the songs of the *Shih Ching,* follow a different metrical pattern: the lines are usually longer and more irregular and are commonly (though not always) marked by a strong caesura in the middle. Their effect is thus rather plaintive, and they lend themselves to chanting instead of singing. The beginning of this tradition is obscure because most of the early samples were eclipsed by the brilliant 4th/3rd-century-BC compositions of the towering genius Ch'ü Yüan, China's first known poet.

Ch'u tz'u

Among some 25 elegies that are attributed to Ch'ü Yüan, the most important and longest is *Li sao* ("On Encountering Sorrow"), which has been described as a politico-erotic ode, relating by means of a love allegory the poet's disappointment with his royal master and describing his imaginary travels in distant regions and the realms of heaven, in an attempt to rid himself of his sorrow. Ch'ü Yüan committed suicide by drowning in the Mi-lo River; and his tragic death, no less than his beautiful elegies, helped to perpetuate the new literary genre. In contrast to the poems of the *Shih Ching,* which had few successful imitators, the genre created by Ch'ü Yüan was cultivated for more than five centuries, and it also experienced later revivals.

Prose. Prior to the rise of the philosophers in the 6th century BC, brief prose writings were reported to be numerous; but of these only two collections have been transmitted: the *Shu,* or *Shu Ching* ("Classic of History"), consisting of diverse kinds of primitive state papers, such as declarations, portions of charges to feudal lords, and orations; and the *I,* or *I Ching* ("Classic of Changes"), a fortune-telling manual. Both grew by accretion and, according to a very doubtful tradition, were edited by Confucius himself. Neither can be considered literature, but both have exerted influence on Chinese writers for more than 2,000 years as a result of their inclusion in the Confucian canon.

The earliest writings that can be assigned to individual "authorship," in the loose sense of the term, are the *Lao-tzu,* or *Tao-te Ching* ("Classic of the Way of Power"), which is attributed to Lao-tzu, who is credited with being the founder of Taoism and who might have been an older contemporary of Confucius; and the *Lun yü* ("Conversations"), or *Analects* (selected miscellaneous passages), of Confucius. Neither of the philosophers wrote extensively, and their teachings were recorded by their followers. Thus, the *Lao-tzu* consists of brief summaries of Lao-tzu's sayings, many of which are in rhyme and others in polished prose to facilitate memorization. Likewise, the *Analects* is composed of collections of the sage's sayings, mostly as answers to questions or as a result of discussions because writing implements and materials were expensive and scarce. The circumstances of the conversations, however, were usually omitted; and as a consequence the master's words often sound cryptic and disjointed, despite the profundity of the wisdom.

Earliest writings claiming individual authorship

By about 400 BC, writing materials had improved, and a change in prose style resulted. The records of the discourses became longer, the narrative portions more detailed; jokes, stories, anecdotes, and parables, interspersed in the conversations, were included. Thus, the *Mencius,* or *Meng-tzu,* the teachings of Mencius, not only is three times longer than the *Analects* of Confucius but also is topically and more coherently arranged. The same characteristic may be noticed in the authentic chapters of the *Chuang-tzu,* attributed to the Taoist sage Chuang-tzu, who "in paradoxical language, in bold words, and with subtle profundity, gave free play to his imagination and thought. . . . Although his writings are inimitable and unique, they seem circuitous and innocuous. Although his utterances are irregular and formless, they are unconventional and readable . . ." (from the epilogue of the *Chuang-tzu*).

Well-developed essay

The first example of the well-developed essay, however, is found neither in the *Mencius* nor in the *Chuang-tzu* but in the *Mo-tzu,* attributed to Mo Ti, or Mo-tzu, a predecessor of Mencius and Chuang-tzu, whose singular attainments in logic made him a forceful preacher. His recorded sermons are characterized by simplicity of style, clarity of exposition, depth of conviction, and directness of appeal.

The prose style continued to be developed by such outstanding philosopher-essayists as Hsün-tzu and his pupil, the Legalist Han-fei-tzu. The peak of this development, however, was not reached until the appearance of the first expertly arranged full-length book, *Lü-shih Ch'un-ch'iu* ("The Spring and Autumn [Annals] of Mr. Lü"), completed in 240 BC under the general direction of Lü Pu-wei. The work, 60 essays in 26 sections, summarizes the teachings of the several schools of philosophy as well as the folklore of the various regions of China.

Ch'in and Han dynasties: 221 BC–AD 220. *Poetry.* Following the unification of the empire by the Ch'in dynasty (221–206 BC) and the continuation of the unified empire under the Han, literary activities took new directions. At the Imperial and feudal courts, the *fu* genre, a combination of rhyme and prose, began to flourish. Long and elaborate descriptive poetic compositions, the *fu* were in form a continuation of the Ch'u elegies, now made to serve a different purpose—the amusement of the new aristocracy and the glorification of the empire—by dwelling on such topics as the low table and the folding screen or on descriptions of the capital cities. But even the best *fu* writing, by such masters of the art as Mei Sheng and Ssu-ma Hsiang-ju, bordered on the frivolous and bombastic. Another major *fu* writer, Yang Hsiung, in the prime of his career remorsefully realized that the genre was a minor craft not worthy of a true poet. Nonetheless, the *fu* was almost universally accepted as the norm of creative writing, and nearly 1,000 pieces were produced.

The *fu* genre

A more important contribution to literature by the Han government was the reactivation in 125 BC of the Yüeh Fu, or Music Bureau, which had been established at least a century earlier to collect songs and their musical scores. Besides temple and court compositions of ceremonial verse, this office succeeded in preserving a number of songs sung or chanted by the ordinary people, including songs from the border areas, which reveal alien influences. This category—called *yüeh-fu,* for the Music Bureau—includes not only touching lyrics but also charming ballads.

Ballads

One such ballad, "The Orphan," tells of an orphan's hardships and disappointments; the form of the poem—lines of irregular length, varying from three to six syllables (or graphs)—represents the singer's attempt to simulate the choking voice of the sufferers. *Lo-fu hsing* ("The Song of Lo-fu"; also called *Mo-shang sang,* "Roadside Mulberry Tree"), recounts how a pretty young lady declined a carriage ride offered her by a government commissioner. The most outstanding folk ballad of this period is *K'ung-ch'üeh tung-nan fei* ("Southeast the Peacock Flies"). The longest

poem of early Chinese literature (353 lines), it relates the tragedy of a young married couple who had committed suicide as the result of the cruelty of the husband's mother. The ballad was probably first sung shortly after AD 200 and grew by accretion and refinement in oral transmission until it was recorded in final form for the first time in about 550. *Yüeh-fu* songs, most of which are made up mainly of five-syllable lines, became the fountainhead of a new type of poetry, *ku-shih* ("ancient-style poems"); contemporary Han dynasty poets at first merely refined the originals of the folk songs without claiming credit and later imitated their fresh and lively metre.

Prose. Prose literature was further developed during the Ch'in and Han dynasties. In addition to a prolific output of philosophers and political thinkers—a brilliant representative of whom is Liu An, prince of Huai-nan, whose work is called *Huai-nan-tzu* (*c.* 140 BC; "The Master of Huai-nan")—an important and monumental category of Han dynasty literature consists of historical works. Outstanding among these is the *Shih-chi* (*c.* 85 BC; "Historical Records," Eng. trans., *The Records of the Grand Historian of China,* 2 vol.) by Ssu-ma Ch'ien. A masterpiece that took 18 years to produce, it deals with major events and personalities of about 2,000 years (down to the author's time), comprising 130 chapters and totaling more than 520,000 words. The *Shih-chi* was not only the first general history of its kind attempted in China, it also set a pattern in organization for dynastic histories of subsequent ages. An artist as well as a historian, Ssu-ma Ch'ien succeeded in making events and personalities of the past into living realities for his readers; his biographies subsequently became models for authors of both fiction and history. Ssu-ma's great successor, the poet-historian-soldier Pan Ku, author of the *Han shu* ("Han Documents"), a history of the Former Han dynasty containing more than 800,000 words, performed a similar tour de force but did not equal Ssu-ma Ch'ien in either scope or style.

Pan Ku's prose style, though not necessarily archaic, was more consciously literary—a result of the ever-widening gap between the spoken and written aspects of the language. This anomaly was more evident in China than elsewhere, and it was to have far-reaching effects on the evolution of Chinese literary tradition. In an attempt to resolve the difficulties of communication among speakers of many dialects in the empire, a standard literary language, *wen-yen,* was promoted from the Han dynasty on. Perpetuated for more than 2,000 years, the literary language failed to keep pace with changes in the spoken tongue, and eventually it became almost unintelligible to the illiterate masses.

Promotion of a standard literary language

The Six Dynasties and Sui dynasty: AD 220–618. After the fall of the Han dynasty, there was a long period of political division (AD 220–589), with barely four decades of precarious unification (AD 280–316/17). Despite the social and political confusion and military losses, however, the cultural scene was by no means dismal. Several influences on the development of literature are noteworthy. First, Buddhism, introduced earlier, had brought with it religious chants and Indian music, which helped to attune Chinese ears to the finer distinctions of tonal qualities in their own language. Second, aggressive northern tribes, who invaded and dominated the northern half of the country from 316, were being culturally absorbed and converted. Third, the political division of the empire between the South and the North (as a result of the domination of non-Chinese in the north) led to an increase in cultural differences and to a subsequent rivalry to uphold what was regarded as cultural orthodoxy, frequently resulting in literary antiquarianism.

Poetry. Folk songs flourished in both regions. In the South, popular love songs, originating in the coastal areas, which now came increasingly under Chinese political and cultural domination, attracted the attention of poets and critics. The songs of the North were more militant. Reflecting this spirit most fully is the *Mu-lan shih* ("Ballad of Mu Lan"), which sings of a girl who disguised herself as a warrior and won glory on the battlefield.

Ts'ao Chih and T'ao Ch'ien

Soon the number of writers of "literary" poetry greatly increased. Among them, two poets deserve special mention. Ts'ao Chih (3rd century), noted for his ethereal lyricism, gave definite artistic form to the poetry of the five-syllable line, already popularized in folk song. T'ao Ch'ien (4th–5th centuries), also known as T'ao Yüan-ming, is one of China's major poets and was the greatest of this period. A recluse, he retired from a post in the bureaucracy of the Chin dynasty at the age of 33 to farm, contemplate nature, and write poetry. His verse, written in a plain style, was echoed by many poets who came after him. Using several verse forms with seemingly effortless ease—including the *fu,* for *Kuei-ch'ü-lai tz'u* ("Homeward Bound")—he was representative of the trend of the age to explore various genres for lyrical expression. One of his best loved poems is the following *ku-shih,* translated by Arthur Waley; it is one of 12 he wrote at different times after he had been drinking.

I built my hut in a zone of human habitation,
Yet near me there sounds no noise of horse or coach.
Would you know how this is possible?
A heart that is distant creates a wilderness round it.
I pluck chrysanthemums under the eastern hedge,
Then gaze long at the distant hills.
The mountain air is fresh at the dusk of day;
The flying birds two by two return.
In these things there lies a deep meaning;
Yet when we would express it, words suddenly fail us.

Prose. As orthodox Confucianism gradually yielded to Taoism and later to Buddhism, nearly all of the major writers began to cultivate an uninhibited individuality. Lu Chi, 3rd-century poet and critic, in particular emphasized the importance of originality in creative writing and discredited the long-established practice of imitating the great masters of the past. Still, his celebrated essay on literature (*Wen fu*), in which he enunciated this principle, was written as a *fu,* showing after all that he was a child of his own age. The 3rd/4th-century Taoist philosopher Ko Hung insisted that technique is no less essential to a writer than moral integrity. The revolt of the age against conventionality was revealed in the new vogue of *ch'ing-t'an* ("pure conversation"), intellectual discussions on lofty and nonmundane matters, recorded in a 5th-century collection of anecdotes entitled *Shih-shuo hsin-yü* ("A New Account of Tales of the World") by Liu Yi-ch'ing. Though prose writers as a whole continued to be most concerned with lyrical expression and rhetorical devices for artistic effect, there were notable deviations from the prevailing usage in the polyphonic *p'ien-wen* ("parallel prose"). In this form, parallel construction of pairs of sentences and counterbalancing of tonal patterns were the chief requirements. *P'ien-wen* was used especially in works concerned with philosophical disputes and in religious controversies; but it was also used in the first book-length work of literary criticism, *Wen-hsin tiao-lung* ("The Literary Mind and the Carving of the Dragon"), by the 6th-century writer Liu Hsieh.

Development of polyphonic prose: *p'ien-wen*

Among prose masters of the 6th century, two northerners deserve special mention: Yang Hsien-chih, author of *Lo-yang Chia-lan chi* ("Record of Buddhist Temples in Lo-yang"), and Li Tao-yüan, author of *Shui Ching chu* ("Commentary on the Water Classic"). Although both of these works seem to have been planned to serve a practical, utilitarian purpose, they are magnificent records of contemporary developments and charming storehouses of accumulated folklore, written with great spontaneity and artistry. This age also witnessed the first impact of Buddhist literature in Chinese translation, which had been growing in size and variety since the 2nd century.

T'ang and Five Dynasties: 618–960. During the T'ang dynasty (618–907), Chinese literature reached its golden age.

Poetry. In poetry, the greatest glory of the period, all the verse forms of the past were freely adopted and refined, and new forms were crystallized. One new form was perfected early in the dynasty and given the definitive name *lü-shih* ("regulated verse"). A poem of this kind consists of eight lines of five or seven syllables—each line set down in accordance with strict tonal patterns—calling for parallel structure in the middle, or second and third, couplets.

Another verse form much in vogue was the *chüeh-chü* ("truncated verse"). An outgrowth and a shortened ver-

Chüeh-chü verse form

sion of the *lü-shih,* it omitted either the first four lines, the last four lines, the first two and the last two lines, or the middle four lines. Thus, the tonal quality of the *lü-shih* was retained, whereas antithetic structure was made optional. These poems of four lines, each consisting of five or seven words (syllables or characters), had to depend for their artistry on suggestiveness and economy comparable to the *robāʿiyāt* ("quatrains") of Omar Khayyam and the Japanese haiku.

The fine distinctions of tonal variations in the spoken language had reached their height during this period, with eight tones; and rules and regulations concerning the sequence of lighter and heavier tones had been formulated. But since the observance of strict rules of prosody was not mandatory in the *ku-shih* ("ancient style") form still in use, it was possible for an individual poet to enjoy conformity or freedom as he saw fit.

Of the more than 2,200 T'ang poets whose works—totaling more than 48,900 pieces—have been preserved, only a few can be mentioned. Wang Wei, a musician and the traditional father of monochrome landscape painting, was also a great poet. Influenced by Buddhism, he wrote exquisite meditative verse of man's relation to nature that exemplified his own dictum that poetry should have the beauty of painting and vice versa. Li Po, one of the two major poets of the T'ang dynasty, a lover of detachment and freedom, deliberately avoided the *lü-shih* and chose the less formal verse forms to sing of friendship or wine. An example is the poem "To Tan-Ch'iu," translated by Arthur Waley.

My friend is lodging high in the Eastern Range,
Dearly loving the beauty of valleys and hills.
At green Spring he lies in the empty woods,
And is still asleep when the sun shines on high.
A pine-tree wind dusts his sleeves and coat;
A pebbly stream cleans his heart and ears.
I envy you, who far from strife and talk
Are high-propped on a pillow of blue cloud.

The works of Tu Fu

Generally considered the greatest poet of China was Tu Fu, a keen observer of the political and social scene who criticized injustice wherever he found it and who clearly understood the nature of the great upheaval following the rebellion of dissatisfied generals in 755, which was a turning point in the fortunes of the T'ang. As an artist, Tu Fu excelled in all verse forms, transcending all rules and regulations in prosody while conforming to and exploiting them. His power and passion can perhaps be suggested by a single line (translated by Robert Payne): "Blue is the smoke of war, white the bones of men."

One of the admirers of Tu Fu as a poet-historian was Po Chü-i who, like his great predecessor, was deeply concerned with the social problems of his age. Po Chü-i sought to learn from ordinary folk not only naturalness of language but also their feelings and reactions, especially at the height of his career when he wrote what he called the *Hsin yüeh-fu shih* ("New Yüeh-fu Poems").

At the end of the T'ang and during the Five Dynasties, another new verse form developed. Composed normally of lines of irregular length and written as lyrics to musical tunes, this form came to be known as *tz'u,* in contrast with *shih,* which includes all the verse forms mentioned above. Since the lines in a *tz'u* might vary from one to nine or even 11 syllables, they were comparable to the natural rhythm of speech and therefore easily understood when sung.

Development of *tz'u*

First sung by ordinary folk, they were popularized by professional women singers and, during the T'ang, attracted the attention of poets. It was not, however, until the transitional period of the Five Dynasties (907–960), a time of division and strife, that *tz'u* became the major vehicle of lyrical expression. Of *tz'u* poets in this period, the greatest was Li Yü, last monarch of the Southern T'ang, who was seized in 976 as the new Sung dynasty consolidated its power. Li Yü's *tz'u* poetry is saturated with a tragic nostalgia for better days in the South; it is suffused with sadness—a new depth of feeling notably absent from earlier *tz'u,* which had been sung at parties and banquets. The following is typical, translated by Jerome Ch'en and Michael Bullock:

Lin hua hsieh liao ch'un hung
T'ai ch'ung ch'ung
Wu nai chao lai han yü wan lai feng
Yen chih lei
Hsiang liu tsui
Chi shih ch'ung
Tzu shih jen sheng ch'ang hen shui ch'ang tung
The red of the spring orchard has faded.
Far too soon!
The blame is often laid
  on the chilling rain at dawn
  and the wind at dusk.
The rouged tears
That intoxicate and hold in thrall—
When will they fall again?
As a river drifts toward the east
So painful life passes to its bitter end.

Folk literature. Besides the early *tz'u,* the end of the T'ang saw the evolution of another new folk form: *pien-wen* ("popularizations," not to be confused with *p'ien-wen,* or parallel prose), utilizing both prose and verse to retell episodes from the Buddha's life and, later, non-Buddhist stories from Chinese history and folklore.

Han Yü's reform of prose

Prose. In prose writing a major reform was led by Han Yü against the peculiarly artificial prose style of *p'ien-wen,* which, cultivated for almost 1,000 years, had become so burdened with restrictive rules as to make forthright expression virtually impossible. Han Yü boldly advocated the use of Chou philosophers and early Han writers as models for prose writing. This seemingly conservative reform had, in fact, a liberalizing effect; for the sentence unit in prose writing was now given perfect freedom to seek its own length and structural pattern as logic and content might dictate, instead of slavishly conforming to the rules of *p'ien-wen.* This new freedom enabled Liu Tsung-yüan, Han Yü's chief associate in the literary reform, to write charming travel and landscape pieces. It also accelerated the development of a new genre in prose: well-made tales of love and romance, of heroic feats and adventures, of the mysterious and supernatural, and of imaginary incidents and fictionalized history. Among the 9th-century writers of such prose romances were Han Yü's pupil Shen Ya-chih and Po Hsing-chien, younger brother of the poet Po Chü-i. These prose romances, generally short, were written in the classical prose style for the amusement of the literati and did not reach the masses until some of the popular ones were adapted by playwrights in later ages.

Sung dynasty: 960–1279. The Sung dynasty was marked by cultural advancement and military weakness. During this period, literary output was spectacularly increased, thanks mainly to the improvement of printing (invented in the 8th century) and to the establishment of public schools throughout the empire (from 1044). Nearly all the literary genres in verse and prose were continued; and some trends, begun in T'ang times, were accelerated.

Prose. In prose, the reform initiated by Han Yü in the name of ancient, more straightforward style (*ku-wen*) was reemphasized by such 11th-century writers as Ou-yang Hsiu and Su Tung-p'o. Both men held high rank in the civil service and were great painters as well as leading poets. Nevertheless, their contribution to prose writing in *ku-wen* style was as important as their poetry. The *ku-wen* movement was further supported by men whose primary interest was not belles lettres, such as Ssu-ma Kuang, the statesman-historian, and Chu Hsi, the scholar-philosopher and principal formulator of Neo-Confucianism.

Sung trends in prose fiction

In prose fiction there were two distinct trends. Short tales in *ku-wen* were written in ever greater bulk but failed to maintain the level achieved in the T'ang dynasty. The subject matter became more fragmentary and anecdotal and the style duller. In sharp contrast to the *ku-wen* school, which was still a literary language despite the movement toward naturalness of expression, there arose a school of storytelling in the vernacular. Almost purely oral in origin, these tales reflected the style of the storyteller who entertained audiences gathered in marketplaces, fairgrounds, or temple yards. In the 12th century they became fairly lengthy, connected stories, especially those dealing with fictionalized history. This elevation of the everyday speech of the common people as a medium of story writing of

the *hua-pen* ("vernacular story") type was to open up new vistas in prose fiction in later periods.

Poetry. Poetry of the conventional type (*shih*) was cultivated by numerous rival schools, each claiming many illustrious members. On the whole, the rival literary movements were significant as steps toward greater naturalness in syntax, and a few outstanding writers approximated the spoken vernacular language. Among the many *shih* poets of the Sung dynasty, Lu Yu, who flourished in the 12th century, was a towering figure. A traveler and patriot, he wrote throughout his long career no fewer than 20,000 poems, of which more than 9,000 have been preserved.

But it was in their utilization of the newer verse form, *tz'u,* that Sung poets achieved their greatest distinction, making *tz'u* the major genre of the dynasty. As noted above, the *tz'u* form had been popularized at first orally by women singers; and the first generation of *tz'u* writers had been inspired and guided by them in sentiment, theme, and diction; their lyrics were thus redolent with the fragrance of these women. Later in the 12th century, as men (and one great woman) of letters began to take over, the *tz'u* form reached the heights of great art. Ou-yang Hsiu and Li Ch'ing-chao, the latter generally considered the greatest woman poet of China, may be considered representatives of this trend. Li Ch'ing-chao's poems, paralleling her life, are intensely personal. They at first dealt with the joys of love, but gradually their tone darkened to one of despair, caused first by frequent and lengthy separations from her husband, who was in government service, and then by his untimely death.

Other masters of the *tz'u* were Su Tung-p'o and Hsin Ch'i-chi, the latter a soldier turned recluse. It was Hsin Ch'i-chi who imbued the writing of *tz'u* with new characteristics by rising above rules without breaking them, surpassing in this respect his contemporaries as well as those who came after him.

Yüan dynasty: 1206–1368. Fleeing from the Chin (Juchen) Tatars, who captured their capital in 1127, the Sung officials and courtiers retreated southward. For almost a century and a half, China was again divided. And in spite of political reunification by Kublai Khan, founder of the Yüan, or Mongol, dynasty (beginning in 1206 in the North and comprising the whole of China by 1280), the cultural split persisted. In the South, where China's historic traditions found asylum, racial and cultural homogeneity persisted. In fact, the centre of Chinese philosophy and traditional literature never again returned north of the Yangtze Delta. But in the North new developments arose, which led to wholly new departures. First, the migration and fusion of the various ethnic groups gave birth to a common spoken language with fewer tones, which later was to become the basis of a national language; second, with the southward shift of the centre of traditional culture, the prestige of the old literature began to decline in the North, especially in the eyes of the conquerors. Thus, in contrast to the South, North China under the Yüan dynasty provided a unique milieu for unconventional literary activities.

Drama. In this period, dramatic literature came into a belated full flowering. The skits and vaudeville acts, the puppet shows and shadow plays of previous ages had laid the foundation for a full-fledged drama; but the availability of Indian and Iranian models during the Yüan dynasty may have been a more immediate cause for its accelerated growth. Many Chinese men of letters refused to cooperate with the alien government, seeking refuge in painting and writing. As the new literary type developed—the drama of four or five acts, complete with prologue and epilogue and including songs and dialogue in language fairly close to the daily speech of the people—many men of letters turned to playwriting. Between 1234 and 1368, more than 1,700 musical plays were written and staged, and 105 dramatists were recorded; moreover, there is an undetermined number of anonymous playwrights whose unsigned works have been preserved but discovered only in the 20th century. This remarkable burst of literary innovation, however, failed to win the respect of the orthodox critics and official historians. No mention of it was made in the copious dynastic history, *Yüan shih;* and casual references in the collected works of contemporary writers were few. Many plays were allowed to fall into oblivion. It was not until 1615 that a bibliophile undertook to reprint, as a collection, 100 of the 200 plays he had seen. Even after ardent searches by 20th-century librarians and specialists, the number of extant Yüan dramas has been increased to only 167, hardly 10 percent of the number produced. Moreover, since the musical scores have been lost, the plays cannot be produced on the stage in the original manner.

Development of a new literary type

Among the Yüan dramatists, the following deserve special mention. Kuan Han-ch'ing, the author of some 60 plays, was the first to achieve distinction. His *Tou-o yüan* ("Injustice Suffered by Tou-o") deals with the deprivations and injustices suffered by the heroine, Tou-o, which begin when she is widowed shortly after her marriage to a poor scholar and culminate in her execution for a crime she has not committed. Wang Shih-fu, Kuan's contemporary, wrote *Hsi-hsiang chi* (*Romance of the Western Chamber*), based on a popular T'ang prose romance about the amorous exploits of the poet Yüan Chen, renamed Chang Chun-jui in the play. Besides its literary merits and its influence on later drama, it is notable for its length, two or three times that of the average Yüan play. Ma Chih-yüan, another contemporary, wrote 14 plays, of which the most celebrated is *Han-kung ch'iu* ("Sorrow of the Han Court"). It deals with the tragedy of a Han dynasty court lady, Wang Chao-chün, who, through the intrigue of a vicious portrait painter, was picked by mistake to be sent away to Central Asia as a chieftain's consort. Like the *Romance of the Western Chamber,* this play has been translated into western European languages.

Characteristics of the new literary genre

This new literary genre acquired certain distinct characteristics: (1) All extant compositions may be described as operas; (2) each play normally consists of four acts following a prologue; (3) the language of both the dialogue (for the most part in prose) and the arias—which alternate throughout the play—are fairly close to the daily speech of ordinary people; (4) all of the arias are in rhymed verse, and only one end rhyme is used throughout an act; (5) all of the arias in an act are sung by only one actor; (6) nearly all of the plays have a happy ending; (7) the characters in most of the plays are people of the middle and underprivileged classes—poor scholars, bankrupt merchants, Buddhist nuns, peasants, thieves, kidnappers, abductors, and women entertainers—antedating a similar trend in European drama by nearly four centuries.

At least 12 of the playwrights thus far identified were Sinicized members of originally non-Chinese ethnic groups—Mongols, Juchens, Uighurs, and other Central Asians.

Poetry. Another literary innovation, preceding but later interacting with the rise of the drama, was a new verse form known as *san-ch'ü* ("nondramatic songs"), a liberalization of the *tz'u,* which utilized the spoken language of the people as fully as possible. Although line length and tonal pattern were still governed by a given tune, extra words could be inserted to make the lyrics livelier and to clarify the relationship between phrases and clauses of the poem. The major dramatists were all masters of this genre.

Vernacular fiction. Similarly, fiction writers who wrote in a semivernacular style began to emerge, continuing the tradition of storytellers of the past or composing lengthy works of fiction written almost entirely in the vernacular. All of the early pieces of this type of book-length fiction were poorly printed and anonymously or pseudonymously published. Although many early works were attributed to such authors as Lo Kuan-chung, there is little reliable evidence of his authorship in any extant work. These novels exist in numerous, vastly different versions that can best be described as the products of long evolutionary cycles involving several authors and editors. The best known of the works attributed to Lo are *San-kuo chih yen-i* (*Romance of the Three Kingdoms*), *Shui-hu chuan* (*The Water Margin*), and *P'ing-yao chuan* ("The Subjugation of the Evil Phantoms"). The best of the three from a literary standpoint is the *Shui-hu chuan,* which gives full imaginative treatment to a long accretion of stories and anecdotes woven around a number of enlightened bandits—armed social and political dissenters.

Composite authorship of novels

Ming dynasty: 1368–1644. The Yüan dynasty was succeeded by the Ming dynasty, under which cultural influences from the South—expressed in movements toward cultural orthodoxy—again became important. Nearly all the major poets and prose writers in traditional literature were southerners, who enthusiastically launched and supported antiquarian movements based on a return to models of various ages of the past. With the restoration of competitive literary examinations, which had been virtually discontinued under the Mongols, the highly schematic *pa-ku wen-chang* ("eight-legged essay") was adopted as the chief yardstick in measuring a candidate's literary attainments. Despite occasional protests, it continued to engage the attention of aspirants to official literary honours from 1487 to 1901.

Classical literature. Although Ming poets wrote both *shih* and *tz'u* and their output was prodigious, poetry on the whole was imitative rather than freshly creative. Tirelessly, the poets produced verses imitating past masters, with few individually outstanding attainments.

Prose writers in the classical style were also advocates of antiquarianism and conscious imitators of the great masters of past ages. Rival schools were formed, but few writers were able to rise above the ruts of conventionalism. The Ch'in-Han school tried to underrate the achievements of Han Yü and Liu Tsung-yüan, along with the Sung essayists, and proudly declared that post-Han prose was not worth reading. The T'ang-Sung school, on the other hand, accused its opponents of limited vision and reemphasized Han Yü's dictum that literature should be the vehicle of Tao, equated with the way of life taught by orthodox Confucianism. These continuous squabbles ultimately led nowhere, and the literary products were only exquisite imitations of their respective models.

The Kung-an school of prose writers

The first voice of protest against antiquarianism was not heard until the end of the 16th century; it came from the Kung-an school, named for the birthplace of three brothers, of whom the middle one was the best known. Yüan Hung-tao challenged all of the prevailing literary trends, advocating that literature should change with each age and that any attempt at erasing the special stamp of an era could result only in slavish imitation. Declaring that he could not smile and weep with the multitude, he singled out "substantiality" and "honesty with oneself" as the chief prerequisites of a good writer.

This same spirit of revolt was shared by Chung Hsing and T'an Yüan-ch'un, of a later school, who were so unconventional that they explored the possibilities of writing intelligibly without observing Chinese grammatical usages. Although their influence was not long lasting, these two schools set the first examples of a new subgenre in prose—the familiar essay.

Vernacular literature. It was in vernacular literature that the writers of this period made a real contribution. In drama, a tradition started in the Sung dynasty and maintained in southern China during the period of Mongol domination was revitalized. This southern drama, also musical and known as *ch'uan-ch'i* ("tales of marvels"), had certain special traits: (1) a *ch'uan-ch'i* play contains from 30 to 40 changes of scene; (2) the change of end rhymes in the arias is free and frequent; (3) the singing is done by many actors instead of by the hero or heroine alone; (4) many plots, instead of being extracted from history or folklore, are taken from contemporary life.

Since there were no rules regulating the structure of the *ch'uan-ch'i,* playlets approaching the one-act variety were also written. This southern theatre movement, at first largely carried on by anonymous amateurs, won support gradually from the literati until finally, in the 16th century, a new and influential school was formed under the leadership of the poet-singer Liang Ch'en-yü and his friend the great actor Wei Liang-fu. The K'un school, initiating a style of soft singing and subtle music, was to dominate the theatre to the end of the 18th century.

Aside from drama and *ta-ch'ü* (a suite of melodies sung in narration of stories), which in the South were noticeably modified in spirit and structure, becoming more ornate and bookish—it was prose fiction that made the greatest progress in the 16th century. Two important novels took shape at that time. Wu Ch'eng-en's *Hsi-yu chi* is a fictionalized account of the pilgrimage of the Chinese monk Hsüan-tsang to India in the 7th century. The subject matter was not new; it had been used in early *hua-pen,* or "vernacular story," books and Yüan drama; but it had never been presented at length in such a lively and rapid-moving narration. Of all of the 81 episodes of trial and tribulation experienced by the pilgrim, no two are alike. Among the large number of monsters introduced, each has unique individuality. Like the *Shui-hu chuan,* it reveals the influence of the style of the oral storytellers, for each chapter ends with the sentence "in case you are interested in what is to follow, please listen to the next installment, which will reveal it." Unlike the *Shui-hu chuan,* which was written in a kind of semivernacular, the language used was the vernacular of the living tongue. For the author the choice must have been a deliberate but difficult one, for he had the novel first published anonymously to avoid disapproval. Besides eliciting numerous commentaries and "continuations" in China, it has two English translations.

Important novels of the 16th century

The title of the second novel (the author of which is unknown), *Chin P'ing Mei,* is composed of graphs from the names of three female characters. Written in an extremely charming vernacular prose style, the novel is a well-knit, long narrative of the awful debaucheries of the villain Ch'ing Hsi-men. The details of the different facets of life in 16th-century China are so faithfully portrayed that it can be read almost as a documentary social history of that age. The sexual perversions of the characters are so elaborately depicted that several Western translators have rendered a number of indelicate passages in Latin. The novel has been banned in China more than once, and all copies of the first edition of 1610 were destroyed.

Ch'ing dynasty: 1644–1911/12. The conquest of China by the Manchus, a Mongol people from the region north of China who set up the Ch'ing dynasty in 1644, did not disrupt the continuation of major trends in traditional literature. (During the literary inquisition of the 18th century, however, many books suspected of anti-Manchu sentiments were destroyed; and numerous literati were imprisoned, exiled, or executed.) Antiquarianism dominated literature as before, and excellent poetry and prose in imitation of ancient and medieval masters continued to be written, many works rivaling the originals in archaic beauty and cadence. Although the literary craftsmanship was superb, genuine creativity was rare.

Poetry and prose nonfiction. In the field of *tz'u* writing, the 17th-century Manchu poet Nara Singde (Sinicized name, Na-lan Hsing-te) was outstanding; but even he lapsed into conscious imitation of Southern T'ang models except when inspired by the vastness of open space and the beauties of nature. In nonfictional prose, Chin Jen-jui continued the familiar essay form.

Prose fiction. P'u Sung-ling continued the prose romance tradition by writing in *ku-wen* ("classical language") a series of 431 charming stories of the uncanny and the supernatural entitled *Liao-chai chih-i* (1766; "Strange Stories from the Liao-chai Studio"; Eng. trans., *Strange Stories from a Chinese Studio*). This collection, completed in 1679, was reminiscent of the early literary tale tradition, for it contained several T'ang stories retold with embellishments and minor changes to delineate the characters more realistically and to make the plots more probable. Such traditional supernatural beings as fox spirits, assuming in these stories temporary human form in the guise of pretty women, became for the first time in Chinese fiction humanized and likable. Despite the seeming success of these tales, the author soon became aware of the limitations of the *ku-wen* style for fiction writing and proceeded to produce a vernacular novel of some 1,000,000 words, the *Hsing-shih yin-yüan chuan* ("A Marriage to Awaken the World"). This long story of a shrew and her henpecked husband was told without any suggestion of a solution to the problems of unhappy marriages. Unsure of the reaction of his colleagues to his use of the vernacular as a literary medium, P'u Sung-ling had this longest Chinese novel of the old school published under a pseudonym.

The prose romances of P'u Sung-ling

Wu Ching-tzu satirized the 18th-century literati in a re-

alistic masterpiece, *Ju-lin wai-shih* (*c.* 1750; "Unofficial History of the Literati"; Eng. trans., *The Scholars*), 55 chapters loosely strung together in the manner of a picaresque romance. Unlike P'u Sung-ling, whom he far surpassed in both narration and characterization, he adopted the vernacular as his sole medium for fiction writing.

Better known and more widely read was Ts'ao Chan's *Hung-lou meng* (*Dream of the Red Chamber*), a novel of a love triangle and the fall of a great family, also written in the vernacular and the first outstanding piece of Chinese fiction with a tragic ending. Because its lengthy descriptions of poetry contests, which interrupt the narrative, may seem tiresome, especially to non-Chinese readers, they have been largely deleted in Western translations. Nevertheless, some Western critics have considered it one of the world's finest novels.

Drama. In drama, the Ming tradition of *ch'uan-ch'i* was worthily continued by several leading poets of the conventional school, though as a whole their dramatic writings failed to appeal to the masses. Toward the end of the 18th century, folk dramas of numerous localities began to gain popularity, converging finally at the theatres of Peking and giving rise to what came to be designated as Peking drama—a composite product that has continued to delight large audiences in China.

Popularity of folk dramas

19th-century translations of Western literature. By the early 19th century, China could no longer ward off the West and, after the first Opium War (1839–42), China's port cities were forcibly opened to increased foreign contacts. In due course, many Western works on diverse subjects were translated into Chinese. The quality of some of these was so outstanding that they deserve a place in the history of Chinese literature. One distinguished translator was Yen Fu, who had studied in Great Britain and whose renderings of Western philosophical works into classical Chinese were acclaimed as worthy of comparison, in literary merit, with the Chou philosophers. Another great translator was Lin Shu, who, knowing no foreign language himself but depending on oral interpreters, made available to Chinese readers more than 170 Western novels, translated into the literary style of Ssu-ma Ch'ien.

19th-century native prose and poetry. Meanwhile, writers of native fiction, especially in central and southern China, began to be seriously influenced by Western models. Using the vernacular and mostly following the picaresque romance structure of the *Ju-lin wai-shih,* they wrote fiction usually intended for serial publication and satirizing Chinese society and culture. One of these writers was Liu E, whose *Lao Ts'an yu-chi* (1904–07; *The Travels of Lao Ts'an*), a fictional account of contemporary life, pointed to the problems confronting the tottering Ch'ing dynasty.

19th-century developments in poetry

Poetry, long stagnant, at last began to free itself from the shackles of traditionalism. The most prominent poet, Huang Tsun-hsien, inspired by folk songs and foreign travel, tried to write poetry in the spoken language and experimented with new themes, new diction, and new rhythm. His young friend Liang Ch'i-ch'ao not only fervently supported Huang and his associates in what they called "the revolution in Chinese poetry" but also ventured forth in new directions in prose. Liang's periodical publications, especially, exerted an extensive influence on the Chinese people in the early years of the 20th century. Fusing all the unique and attractive features of the various schools of prose writing of the past into a new compound, Liang achieved a vibrant and widely imitated style of his own, distinguished by several characteristics: flexibility in sentence structure so that new terms, transliterations of foreign words and phrases, and even colloquial expressions could be accommodated; a natural liveliness; a touch of infectious emotionalism, which the majority of his readers enjoyed. Although he was too cautious to use the vernacular, except in fiction and plays, he did attempt to approximate the living speech of the people, as Huang Tsun-hsien had done in poetry.

As part of a westernization movement, the competitive literary examination system, which had been directly responsible for excessive conservatism and conventionality in thought as well as in literature, was abolished in 1905.

(T.-y.L./W.H.N.)

Modern Chinese literature. *May Fourth period.* Following the overthrow of the Manchu dynasty and the establishment of the Republic in 1912, many young intellectuals turned their attention to the overhauling of literary traditions, beginning with the language itself. In January 1917 an article by Hu Shih, a student of philosophy at Columbia University, entitled "Wen-hsüeh kai-liang ch'u-i" ("Tentative Proposal for Literary Reform") was published in the Peking magazine *Hsin ch'ing-nien* (*New Youth*). In it Hu called for a new national literature written not in the classical language but in the vernacular, the living "national language" (*kuo-yü*). Ch'en Tu-hsiu, the editor of *Hsin ch'ing-nien,* supported Hu's views in his own article "Wen-hsüeh ko-ming lun" ("On Literary Revolution"), which emboldened Hu to hone his arguments further in a second article (1918), entitled "Chien-she te wen-hsüeh ko-ming" ("Constructive Literary Revolution"), in which he spelled out his formula for a "literary renaissance." The literary reform movement that began with these and other "calls to arms" was a part of the larger May Fourth Movement for cultural and sociopolitical reform, whose name commemorates a 1919 student protest against the intellectual performance of the Chinese delegates to the Paris Peace Conference formally terminating World War I. At the outset, the literary reformers met with impassioned but mostly futile opposition from classical literati such as the renowned translator Lin Shu, who would largely give up the battle within a few years.

The first fruits of this movement were seen in 1918 and 1919 with the appearance in *Hsin ch'ing-nien* of such stories as "K'uang-jen jih-chi" ("The Diary of a Madman"), a Gogol-inspired piece about a "madman" who suspects that he alone is sane and the rest of the world is mad, and "Yao" ("Medicine"), both by Chou Shu-jen. Known by the pseudonym Lu Hsün, Chou had studied in Japan and, with his younger brother, the noted essayist Chou Tso-jen, had become a leader of the literary revolution soon after returning to China. Lu Hsün's acerbic, somewhat westernized, and often satirical attacks on China's feudalistic traditions established him as China's foremost critic and writer. His "Ah Q cheng-chuan" (1921; "The True Story of Ah Q"), a damning critique of early 20th-century conservatism in China, is the representative work of the May Fourth period and has become an international classic.

Literary associations

These early writings provided the impetus for a number of youthful intellectuals to pool their resources and promote shared ideals by forming literary associations. The Wen-hsüeh yen-chiu hui ("Literary Research Association"), generally referred to as the "realist" or "art-for-life's-sake" school, assumed the editorship of the established literary magazine *Hsiao-shuo yüeh-pao* (*Short Story Monthly*), in which most major fiction writers published their works throughout the 1920s, until the magazine's headquarters was destroyed by Japanese bombs in 1932. The socially reflective, critical-realist writing that characterized this group held sway in China well into the 1940s, when it was gradually eclipsed by more didactic, propagandistic literature. Members of the smaller Ch'uang-tsao she ("Creation Society"), on the other hand, were followers of the "Romantic" tradition who eschewed any expressions of social responsibility by writers, referring to their work as "art for art's sake." In 1924, however, the society's leading figure, Kuo Mo-jo, converted to Marxism, and the Creation Society evolved into China's first Marxist literary society. Much of the energy of members of both associations was expended in translating literature of other cultures, which largely replaced traditional Chinese literature as the foundation upon which the new writing was built. This was particularly true in drama and poetry, in which figures such as Henrik Ibsen and Rabindranath Tagore, respectively, were as well known to Chinese readers as indigenous playwrights and poets. In drama, the Nan-kuo she ("South China Society"), founded by the former Creationist T'ien Han, produced and performed several short plays that were a mixture of critical realism and melodrama, while poets of the Hsin-yüeh she ("Crescent Moon Society") such as the British-educated Hsü Chih-mo and the American-educated Wen I-to were creating new forms based on Western models, introducing the beauty of mu-

sic and colour into their extremely popular lyrical verse.

1927–37. Political events of the mid-1920s, in which Nationalist, Communist, and warlord forces clashed frequently, initiated a shift to the left in Chinese letters, culminating in 1930 in the founding of the Tso-i tso-chia lien-meng ("League of Leftist Writers"), whose membership included most influential writers. Lu Hsün, the prime organizer and titular head throughout the league's half-decade of activities, had stopped writing fiction in late 1925 and, after moving from Peking to Shanghai in 1927, directed most of his creative energies to translating Russian literature and writing the bitingly satirical random essays (*tsa-wen*) that became his trademark. Among the many active prewar novelists, the most successful were Mao Tun, Lao She, and Pa Chin.

Mao Tun, a founder of the Literary Research Association, was the prototypical Realist. The subjects of his socially mimetic tableaux included pre-May Fourth urban intellectual circles, bankrupt rural villages, and, in perhaps his best known work, *Tzu-yeh* (1933; *Midnight*), metropolitan Shanghai in all its financial and social chaos during the post-Depression era.

Lao She, modern China's foremost humorist, whose early novels were written while he was teaching Chinese in London, was deeply influenced by traditional Chinese storytellers and the novels of Charles Dickens. His works are known for their episodic structure, racy northern dialect, vivid characterizations, and abundant humour. Yet it was left to him to write modern China's classic novel, the moving tale of the gradual degeneration of a seemingly incorruptible denizen of China's "lower depths"—*Lo-t'o hsiang-tzu* (1936; "Camel Hsiang-tzu," published in English in a bowdlerized translation as *Rickshaw Boy,* 1945).

Pa Chin, a prominent Anarchist, was the most popular novelist of the period. A prolific writer, he is known primarily for his autobiographical novel *Chia* (1931; *The Family*), which traces the lives and varied fortunes of the three sons of a wealthy, powerful family. The book is a revealing portrait of China's oppressive patriarchal society, as well as of the awakening of China's youth to the urgent need for social revolution.

The 1930s also witnessed the meteoric rise of a group of novelists from Northeast China (Manchuria) who were driven south by the Japanese annexation of their homeland in 1932. The sometimes rousing, sometimes nostalgic novels of Hsiao Chün and Hsiao Hung and the powerful short stories of Tuan-mu Hung-liang became rallying cries for anti-Japanese youth as signs of impending war mounted.

Poetry of the 1930s underwent a similar politicization, as more and more students returned from overseas to place their pens in the service of the "people's resistance against feudalism and imperialism." The lyrical verse of the early Crescent Moon poets was replaced by a more socially conscious poetry by the likes of Ai Ch'ing, T'ien Chien, and Tsang K'o-chia that appealed to the readers' patriotic fervour. Others, particularly those who had at first gravitated toward the Crescent Moon Society, began striking out in various directions: notable works of these authors include the contemplative sonnets of Feng Chih, the urbane songs of Peking by Pien Chih-lin, and the romantic verses of Ho Ch'i-fang. Less popular, but more daring, were Tai Wang-shu and Li Chin-fa, poets of the Hsien-tai ("Contemporary Age") group, who wrote very sophisticated, if frequently baffling, poetry in the manner of the French Symbolists.

While fiction reigned supreme in the 1930s, as the art of the short story was mastered by growing numbers of May Fourth writers, and novels were coming into their own, the most spectacular advances were made in drama, owing largely to the efforts of a single playwright. Although realistic social drama written in the vernacular had made its appearance in China long before the 1930s, primarily as translations or adaptations of Western works, it did not gain a foothold on the popular stage until the arrival of Ts'ao Yü, whose first play, *Lei-yü* (1934; *Thunderstorm*), a tale of fatalism, retribution, and incestual relations among members of a rich industrialist's family, met with phenomenal success. It was followed over the next several years by other critically and popularly acclaimed plays, including *Jih-ch'u* (1936; *Sunrise*) and *Yüan-yeh* (1937; *Wilderness*), all of which examined pressing social issues and universal human frailties with gripping tension and innovative dramaturgy. Political realities in future decades would force a steady decline in dramatic art, so that Ts'ao Yü's half-dozen major productions still stand as the high-water mark of modern Chinese theatre. Yet, even though movies, television, and other popular entertainments would weaken the resiliency of this literary form, it would still serve the nation as an effective propaganda medium, particularly during the war of resistance.

The plays of Ts'ao Yü

The war years: 1937–45. During the Sino-Japanese War, most writers fled to the interior, where they contributed to the war effort by writing patriotic literature under the banner of the Chung-hua ch'üan-kuo wen-i chieh k'ang-ti hsieh-hui ("All-China Anti-Japanese Federation of Writers and Artists"), founded in 1938 and directed by Lao She. All genres were represented, including reportage (*pao-kao wen-hsüeh*), an enormously influential type of writing that was a natural outgrowth of the federation's call for writers to go to the countryside and the front lines. Literary magazines were filled with short, easily produced and adaptable plays, topical patriotic verse, and war-zone dispatches. Among the major writers who continued to produce work of high quality during this period were Pa Chin, Ts'ao Yü, Mao Tun, and Ting Ling. The latter's fictional explorations of the female psyche and the social condition of women had caught the public's imagination in the 1920s, and in the late 1930s she established herself as the major literary figure in the Communist stronghold of Yen-an.

The growing dissatisfaction of intellectuals with the Nationalist government in Chungking surfaced dramatically during the civil war that raged throughout China following Japan's surrender, ending with the Nationalists' retreat to Taiwan and the establishment, in October 1949, of the People's Republic of China. Most writers, feeling intense pride and welcoming the challenge, chose to remain on the mainland and serve the new government.

1949 to the present. Literature on the China mainland since 1949 has largely been a reflection of political campaigns and ideological battles. This state of affairs can be traced to Mao Tse-tung's 1942 "Tsai Yen-an wen-i tso-t'an-hui shang te chiang-hua" ("Talks at the Yenan Forum on Literature and Art"), in which he articulated his position that literature, which existed to serve politics, was to be popularized while the people's level of literary appreciation was gradually being elevated. Mao's call for a truly proletarian literature—written by and for workers, peasants, and soldiers—gave rise to a series of rectification campaigns that further defined and consolidated party control over literary activities. In 1949, the First National Congress of Writers and Artists was convened, and the All-China Federation of Literature and Art Circles was founded, with Kuo Mo-jo elected as its first chairman.

Mao's "Talks at the Yenan Forum"

Mao's literary ideals had first been realized in the 1940s by Chao Shu-li, whose early stories, such as "Li Yu-ts'ai pan-hua" ("The Rhymes of Li Yu-ts'ai"), were models of proletarian literature, both in form and in content. As the civil war neared its conclusion, novels of land reform, such as Ting Ling's prizewinning *T'ai-yang chao tsai Sang-kan-ho shang* (1949; *The Sun Shines over the Sangkan River*) and *Pao-feng tsou-yü* (1949; *The Hurricane*) by Chou Li-po, became quite popular. Few of the established May Fourth writers continued to produce fiction after 1949, for their experience as social critics did not prepare them for Socialist Realism, a method of composition, borrowed from the Soviet Union, according to which society is described as it should be, not necessarily as it is. Many of the older poets, however, were successful during the early postliberation years, writing poetry in praise of land reform, modernization, and Chinese heroes of the Korean War. Playwrights were also active, introducing more proletarian themes into their works, some of which incorporated music. By this time, Lao She had begun writing plays, such as *Lung-hsü kou* (1951; *Dragon Beard Ditch*), which earned him the prestigious title of People's Artist. Another very popular play, *Pai-mao nü*

(1953; *White-Haired Girl*) by Ho Ching-chih, was taken from a contemporary folk legend.

During the mid-1950s, an experiment in liberalization—the Hundred Flowers Campaign—was abruptly terminated as criticism of the party went beyond all expectations; it was followed by an anti-rightist movement that purged the cultural ranks of most preliberation writers and artists. The literary nadir, however, was not reached until the Cultural Revolution (1966–76), when the only literature available were a few carefully screened works by Lu Hsün, a handful of model revolutionary Peking operas, and the revolutionary-romantic novels of Hao Jan. After the death of Mao and the fall of the Gang of Four, literature made a comeback and most surviving writers were rehabilitated, although the progress was as rocky as the political scene Chinese literature continued to reflect.

The accusatory "scar literature," a sort of national catharsis that immediately followed the 10-year "holocaust," gave way to more professional and more daring writing, as exemplified in the stories of Wang Meng, with their stylistic experiments in stream of consciousness; the symbolic "obscure" poetry of Pei Tao and others; the relatively bold dramas, both for the stage and for the screen, of several playwrights; and the innovative investigative reportage of Liu Pin-yen. In addition to translated literature from the West, literature from Taiwan also began to reach mainland writers and readers as literary restrictions continued to fall gradually.

Taiwanese literature after 1949. The first decade of literary activities in Taiwan after 1949 was characterized by stereotypical anti-Communist fiction and drippingly sentimental essays and poetry, producing little memorable literature other than novels such as *Yang-ko* (1954; *The Rice-Sprout Song*) by Chang Ai-ling, a story of peasant life under Communist rule, and *Hsüan-feng* (1959; *The Whirlwind*), Chiang Kuei's novel of power struggles in Shantung. In the 1960s, however, a group of Taiwan University students ushered in the modernist era by publishing their own craftsmanlike stories, which were heavily indebted to such Western masters as Franz Kafka, James Joyce, and Virginia Woolf. Many of these writers, such as Pai Hsien-yung, author of *Yu-yüan ching-meng* (1982; *Wandering in the Garden, Waking from a Dream*), remained active and influential in the mid-1980s. Vernacular poetry in Taiwan developed around several societies in which modernist, even surrealist, verse was in vogue. These poets, while not widely accepted by the reading public, strongly influenced the more accessible poets who followed. The late 1960s witnessed the rise of regional (*hsiang-t'u*) writing, in which the Taiwanese countryside served as the setting for fiction and poetry that effectively captured the dramatic social and psychological effects of transition from a rural to an urban-based society. Huang Ch'un-ming's *Ni-szu i-chih lao-mao* (1980; *The Drowning of an Old Cat*) is representative of this nativist school, which in later years gave way to a more nationalistic literature that reflected Taiwan's current political situation. Mainland literature occasionally appears in Taiwanese periodicals, while firsthand experiences and observations by mainland émigrés and overseas Chinese, such as the collection of stories *Yin hsien-chang* (1976; *The Execution of Mayor Yin*) by Ch'en Jo-hsi, are given broad exposure.

Taiwanese regionalism

Chordates

The phylum Chordata (chordates) consists of three subphyla: Tunicata (also called Urochordata), Cephalochordata (also called Acrania), and Vertebrata (also called Craniata). As the name implies, at some time in the life cycle a chordate possesses a stiff, dorsal supporting rod (the notochord). Also characteristic of the chordates are a tail that extends behind and above the anus, a hollow nerve cord above (or dorsal to) the gut, gill slits opening from the pharynx to the exterior, and an endostyle (a mucus-secreting structure) or its derivative between the gill slits. (A characteristic feature may be present only in the developing embryo and may disappear as the embryo matures into the adult form.) A somewhat similar body plan can be found in the closely related phylum Hemichordata.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313, and the *Index*.

This article is divided into the following sections:

CHORDATES: THE PHYLUM CHORDATA

GENERAL FEATURES

Tunicates are small animals, typically one to five centimetres (0.4 to 2.0 inches) long, with a minimum length of about one millimetre (0.04 inch) and a maximum length slightly more than 20 centimetres; colonies may grow to 18 metres (59 feet) in length. Cephalochordates range from one to three centimetres. Vertebrates range in size from tiny fish to the whales, which include the largest animals ever to have existed.

Tunicates are marine animals, either benthic (bottom dwellers) or pelagic (inhabitants of open water), that often form colonies by asexual reproduction. They feed by taking water in through the mouth, using the gill slits as a kind of filter. The feeding apparatus in cephalochordates is similar. They have a well-developed musculature and can swim rapidly by undulating the body. Cephalochordates usually live partially buried in marine sand and gravel.

Evolutionary changes

Vertebrates retain traces of a feeding apparatus like that of tunicates and cephalochordates. The gill slits, however, ceased to function as feeding structures, and then later as respiratory devices, as the vertebrate structure underwent evolutionary changes. Except in some early branches of the vertebrate lineage (*i.e.*, agnathans) a pair of gill arches has become modified so as to form jaws. The fishlike habitus that evidently began with cephalochordates became modified by the development of fins that were later transformed into limbs. With the invasion of the vertebrates into fresh water and then onto land, there was a shift in means of breathing—from gills to lungs. Other modifications, such as an egg that could develop on land, also emancipated the vertebrates from water. Elaboration of the locomotory apparatus and other developments allowed a diversification of structure and function that produced the amphibians, reptiles, birds, and mammals.

NATURAL HISTORY

Reproduction and life cycle. The chordate life cycle begins with fertilization (the union of sperm and egg). In its primitive form, fertilization occurs externally, in the water. Asexual reproduction takes place in tunicates and in some vertebrates (females of some fish and lizards can reproduce without fertilization). Hermaphroditism (possessing both male and female reproductive organs) is found in tunicates and some fishes, but otherwise the sexes are separate. Larvae (very young forms that differ considerably from the juveniles and adults), when they do occur, differ in structure from the larvae of nonchordates. Internal fertilization, viviparity (giving birth to young that have undergone embryological development), and parental care are common in tunicates and vertebrates.

Ecology and habitats. Chordates are common in all major habitats. Tunicate larvae either seek out a place where they can attach and metamorphose into an adult or develop into adults that float in the open water. Cephalochordates develop in the open water, but as adults they lie partially or entirely buried in sand and gravel. In either case, they are filter feeders with simple behaviour. Vertebrates are much more complex and, in keeping with their more active manner of obtaining food, highly varied in their ecology and habits.

Muscular movements

Locomotion. Chordates are capable of locomotion by means of muscular movements at some stage in life. In tunicate larvae, this is accomplished using a tail; in cephalochordates, by undulations of the body; and in vertebrates, by general body movements (as in eels and snakes) and by the action of fins and limbs, which in birds and some mammals are modified into wings.

Associations. Chordates enter into a wide variety of symbiotic relationships and are especially noteworthy as hosts for parasites. Family groups and societal relationships, in both a broad and narrow sense, are particularly well developed in vertebrates, due primarily to their elaborate nervous systems. This phenomenon is seen in schools of fish, flocks of birds, and herds of mammals, as well as in the primate associations that suggest the beginnings of human society.

FORM AND FUNCTION

General features. Chordates have many distinctive features, suggesting that there has been extensive modification from simple beginnings. The early stages of chordate development show features shared with some invertebrate phyla, especially the mouth that forms separately from the anus, as it does in the phyla Hemichordata, Echinodermata, and Chaetognatha. Likewise, as in these phyla, the coelom, or secondary body cavity around the viscera, develops as outpouchings of the gut. A coelom also is present in some more distantly related phyla, including Annelida, Arthropoda, and Mollusca, but the main organs of the body are arranged differently in these phyla. In chordates the main nerve cord is single and lies above the alimentary tract, while in other phyla it is paired and lies below the gut. Cephalochordates and vertebrates are segmented, as are the annelids and their relatives; however, segmentation in the two groups probably evolved independently. The gill slits and some other features that are common among the hemichordates and the chordates originated before the chordates became a separate group. Hemichordates have no tail above the gut and no mucus-secreting endostyle between the gill slits.

Coelom

External features. An ancestral chordate, as suggested by the adult lancelet and the tadpole larva of tunicates, had a distinct front and hind end, an anterior mouth, a posterior tail above an anus, unpaired fins, and gill slits that opened directly to the exterior. A free-swimming tunicate larva metamorphoses into an attached, sessile adult with an atrium that surrounds the gills. The atrium of lancelets probably evolved independently.

Internal features. *Skeleton and support.* The chordate notochord is a stiff rod with a turgid core and fibrous sheath. It keeps the animal from shortening when locomotory waves are produced through muscular contraction. The chordate body is supported by fluid in the body cavities. In tunicates, added support is provided by the tunic. Cartilaginous material supports the gills and other body parts of tunicates and cephalochordates. Immature vertebrate skeletons generally consist largely of cartilage, which becomes increasingly bony with age. The cartilaginous skeletons of sharks and some other vertebrates are thought to have evolved from more highly mineralized ones.

Cartilage

Tissues and muscles. In both cephalochordates and vertebrates, muscles used in locomotion are well developed and organized segmentally. The tail musculature of tunicates is simpler and without clear indications of segmentation. There is at least a small amount of musculature throughout the body of all chordates. As jaws, limbs, and other body parts have evolved in vertebrates, so have the muscles that operate them.

Nervous system and sense organs. The anterior end of the main nerve cord in chordates is enlarged to form at least the suggestion of a brain, but a brain is well developed only in vertebrates. Tunicate larvae have visual organs sensitive to light and sense organs responsive to the direction of gravity. Pigment spots and light receptors in the nerve cord of lancelets detect sudden changes in light intensity. The eyes and other sense organs of vertebrates are more elaborate and complex.

The presence in cephalochordates and vertebrates of a nervous system with segmentally repeated nerves arising from the dorsal hollow nerve cord is suggestive of a common ancestry. The tunicate nervous system does not have the segmentally repeated nerves. The brains of all vertebrates are greatly enlarged and subdivided into functionally specialized regions.

Digestion and nutrition. Both tunicates and cephalochordates are filter feeders of small particles of food suspended in the water. Beating cilia (hairlike cellular extensions) on the gill slits draw a current of water into the mouth and through the pharynx, where a sheet of mucus, secreted by the endostyle (a glandular organ lying below the two rows of gill slits), filters suspended food particles from the water. Cilia lining the pharynx move the food-rich sheet of mucus upward over the gill slits, and it is then rolled up and transported to the posterior part of the gut. The water current passes into the atrium and exits through the atrial opening.

Endostyle

Something similar to this arrangement occurs in the vertebrates in the "ammocoetes" larva stage of the primitive jawless fish called the lamprey. The difference is that the food consists of somewhat larger particles that have been deposited on the bottom (detritus), and, instead of the feeding current being driven by cilia, the pharyngeal musculature pumps water and food particles across the gill slits. The earliest fishes probably fed on detritus, and a sucking action is retained by their extant representatives (lampreys and hagfishes). With the development of jaws, it became possible for the vertebrates to capture and seize larger food items.

The lower digestive tract of the primitive chordate is a simple tube with a saclike stomach. There are only indications of the specialized areas and of glandlike structures, such as the liver and pancreas, that occur in vertebrates.

Excretion. The excretion of wastes and the control of the chemical composition of the internal environment are largely effected by kidneys, although other parts of the body, including the gills, may play an important role. Tunicates and cephalochordates have a salt content essentially the same as seawater, but vertebrates, even marine species, have body fluids of low salt content, with the exception of hagfishes. A possible explanation is that the vertebrates evolved in fresh water, but it seems reasonable that hagfishes branched off while still marine and that the freshwater form evolved later.

Respiration. A primitive chordate gill is present in tunicates and cephalochordates, where it serves in both respiration and feeding. The vertebrate gill may retain some role in feeding, although the current is now produced by the action of muscles, not cilia. The gills became reduced in number in various lineages, and they were strengthened by supporting elements, some of which evolved into jaws. Lungs, already present in fishes, became the main respiratory organs of terrestrial vertebrates.

Evolution in gill structure

Circulatory system. The circulatory system in chordates has a characteristic pattern. In tunicates and vertebrates the blood is propelled by a distinct heart; in cephalochordates, by contraction of the blood vessels. Unoxygenated blood is driven forward via a vessel called the ventral aorta. It then passes through a series of branchial arteries in the gills, where gas exchange takes place, and the oxygenated blood flows to the body, much of it returning to its origin via a dorsal aorta. The blood of vertebrates passes through the tissues via tiny vessels called capillaries. In tunicates and cephalochordates, capillaries are absent and the blood passes through spaces in the tissues instead.

Hormones. In vertebrates, endocrine glands (those of internal secretion) produce hormones that regulate many physiological activities. In tunicates and cephalochordates, organs have been identified that correspond in anatomical position to the pituitary gland of vertebrates, but which hormones, if any, they secrete is uncertain. In vertebrates, the thyroid gland produces thyroxine, an iodine-containing hormone that helps regulate metabolism. The thyroid is a modified endostyle, as can be illustrated by larval lampreys in which the thyroid still secretes mucus for use in feeding. The endostyles of lancelets take up iodine and form thyroxine, but the thyroxine formed may not function as a hormone in the lancelets themselves.

Features of defense and aggression. Tunicates largely rely upon the passive defense afforded by their heavy tunic. Lancelets move rapidly through the substrate, and their well-developed locomotory apparatus evolved largely to provide a means of escaping predators. Vertebrates have ceased to feed on detritus brought to them by water currents. They have shifted to consuming larger foodstuffs and to actively locating, pursuing, and subduing what they eat.

EVOLUTION AND PALEONTOLOGY

Chordates originated sometime earlier than 590 million years ago; that is, they predate the fossil record. Early representatives were soft-bodied, and they therefore left a poor fossil record. Fossils dubiously attributed to all three chordate subphyla have been found in Cambrian rocks (more than 505 million years old), and an extensive vertebrate fossil record begins around 400 million years ago.

Embryological evidence places the phylum Chordata within the deuterostomes (bilaterally symmetrical animals with undeterminate cleavage and whose mouth does not arise from the blastopore), which also includes the phyla Hemichordata, Echinodermata, and Chaetognatha. The closest relatives of the chordates are probably the hemichordates, since these animals possess gill slits and other features not found in other animal phyla. A slightly more remote relationship to the echinoderms is inferred on the basis of resemblances between the larvae in some groups of hemichordates and echinoderms. The derivation of chordates from certain fossil echinoderms has been argued on the basis of features such as what appear to be gill slits. Theories that derive them from other phyla (*e.g.,* Annelida, Nemertea, Arthropoda) have been proposed, but such theories have few contemporary advocates.

Whether the ancestral chordate was more like a tunicate or a cephalochordate has been extensively debated. The classical theory is that the ancestor was like a cephalochordate, and that one lineage became attached to hard surfaces and evolved into tunicates, whereas another remained unattached and evolved into vertebrates. An alternative theory is that the ancestor was like a tunicate and that the other two subphyla arose by modification of the tadpole larva. There is some preference for the classical theory because it provides the most satisfactory way of accounting for the similarities between chordates and hemichordates of the subphylum Enteropneusta. Within the chordates the tunicates probably branched off before the common ancestor of cephalochordates and vertebrates arose, for the latter resemble each other in some details of neuroanatomy and biochemistry.

CLASSIFICATION

Annotated classification.

PHYLUM CHORDATA
Deuterostomatous eucoelomates; gill clefts; endostyle or its derivative in pharynx; notochord; hollow dorsal nerve cord; tail posterior and dorsal to anus.

Subphylum Tunicata (or **Urochordata**; tunicates)
Notochord, when present, restricted to tail; body covered with tunic, but sometimes only cuticle; atrium, absent in Appendicularia, dorsal and often paired in embryonic development; heart present; generally sessile (attached) as adults; see below *Tunicates.*

Class Ascidiacea (sea squirts)
Sessile; benthic; solitary or colonial within a common tunic.

Class Appendicularia (larvacea)
Free-swimming; pelagic; resembles tadpole larvae of ascidians; 1 pair of gill slits; no distinct atrium.

Class Thaliacea
Pelagic; forms aggregations or colonies.

Subphylum Cephalochordata (or **Acrania**; lancelets)
Notochord extends entire body length, with tip anterior to nerve cord; atrium a single cavity with single, ventral opening; segments well developed; head poorly developed; no paired fins; no heart; see below *Cephalochordates.*

Subphylum Vertebrata (or **Craniata**; vertebrates)
Notochord extends to the back of a well-developed head; no atrium; segments well developed; paired fins or limbs usually present; heart present; see below *Vertebrates.*

Critical appraisal. This outline gives the major groups of chordates; for lesser units see the sections below on *Tunicates, Cephalochordates,* and *Vertebrates.* Modern systematic biology attempts to arrange groups of organisms in a way that suggests the genealogical relationships (branching sequences) and therefore presents an epitome of evolutionary history. It also may attempt to show where there are important differences among the various groups. These goals often conflict. In a purely genealogical system, each group must correspond to a single lineage (clade) composed of the common ancestor and all of its descendants. A group that does not meet both of these requirements is called a grade and may be used as an informal group. Groups that do not contain the common ancestor, and therefore had two separate origins, are said to be polyphyletic. Such polyphyletic grades, which would put whales together with fish or birds together with bats, have generally been abandoned as soon as they were recognized. Another kind of grade, which does not include all the descendants of the common ancestor, is said to be paraphyletic and is retained in more conservative systems. Within the vertebrates the class Aves is a clade, but the class Reptilia is a grade, for the birds are modified dinosaurs. Some systems do not recognize Reptilia as a formal group. Likewise, birds, mammals, reptiles, and amphibians are all modified fish, and the old class of fishes (Pisces) is now rarely used. Vertebrata is a single clade, but "invertebrate" is a grade consisting of all animals except vertebrates. Therefore there is no formal group called Invertebrata.

Many differences among systems are quite subjective. This is often the case when a group may be ranked either as a class or as a subphylum. The organizational limits of some groups are also largely a matter of opinion. Some authors have placed the phylum Hemichordata within the Chordata, expressing the close genealogical relationship. Others prefer to keep them as a separate phylum because hemichordates lack what are considered important chordate features.

MAJOR CHORDATE GROUPS

Tunicates

Adult members of the subphylum Tunicata (also called Urochordata) commonly are embedded in a tough, secreted tunic containing cellulose (a glucose polysaccharide not normally found in animals). All tunicates are marine; the less modified forms are benthic (bottom-dwelling and sessile), while the more advanced forms are pelagic (floating and swimming in open water). A characteristic tadpole larva develops in the life cycle, and in one group the adult closely resembles this larva, which has many features in common with other chordates.

GENERAL FEATURES

Tunicate classes

Size range and diversity of structure. The tunicates are divided into three classes: Ascidiacea (ascidians, or sea squirts), Appendicularia, and Thaliacea. Ascidians are largely benthic animals. They often form colonies, comprising a few to many individuals (zooids), which reach up to two metres in length. Solitary (noncolonial) forms range from one millimetre to over 20 centimetres in length. The adult appendicularian resembles the tadpole larva of other tunicates. The body is enveloped in a "house," with which the animal nets food. Small (usually around five millimetres in length, including the tail) and simple, appendicularians do not form colonies. They spend their entire lives in the open sea. The thaliaceans (pyrosomes, dolioloids, and salps) are also pelagic. Their structure suggests that they are ascidians modified in adaptation to conditions in open water. They have specialized modes of reproduction, sometimes with a complicated alteration of sexual and asexual generations. Pyrosomes form long, tubular colonies. Dolioloids and salps occur both as solitary individuals and as chains.

Distribution and abundance. Tunicates are distributed in ocean waters from the polar regions to the tropics. Free-swimming tunicates are found throughout the oceans as plankton, while sessile forms grow mainly on solid surfaces such as wharf piles, ship hulls, rocks, and the shells of various sea creatures.

Importance. Although rarely eaten by humans, tunicates are an important link in the food chain and thus indirectly provide humans with a source of food. Tunicates contain some unusual chemicals, and some of these may prove useful as drugs. Some tunicates are fouling organisms that grow on ships' hulls. Their main interest to humans is in providing clues to the possible ancestry of vertebrates.

NATURAL HISTORY

Reproduction and life cycle. With rare exceptions, tunicates are hermaphrodites, but reproduction may be by sexual or asexual (budding) means. In general, hermaphroditic animals do not self-fertilize (*i.e.*, provide both the male and female gametes) if they can avoid doing so, a rule that seems also to be true of tunicates. In primitive forms the eggs are fertilized, and development takes place, in the surrounding water, but often embryos are retained in the female's atrium or elsewhere until the larva is developed.

Larvae

The larval stage is brief; the larva does not feed, but concentrates on finding an appropriate place for the adult to live. In keeping with this motile phase, the muscular tail comprises two-thirds of the larval body; it is supported by a notochord and contains a nerve cord. Gravity- and light-sensitive sensory vesicles along the dorsal surface of the larval body orient the animal as it swims. After a period of up to a few days, the larva will settle and attach itself to a surface using three anterior adhesive papillae. As the larva metamorphoses into an adult, the tail resorbs, providing food reserves for the developing animal. Free-swimming tunicates metamorphose without attachment.

Colonies are formed by asexual reproduction, with zooids usually being formed by budding. In thaliaceans, two groups (dolioloids and salps) have a complex system of alternating generations; the first generation reproduces by budding, and the products of this budding release sperm and eggs.

Locomotion. Tadpole larvae and appendicularians swim by undulating the tail. Despite their sessile life-styles, some adult ascidians can move by attaching with one area of the body and letting go with another. Movement of colonies up to 1.5 centimetres per day has been recorded. In thaliaceans an exhalant current of water, which in dolioloids and salps is combined with a strong muscular contraction, creates a jet stream that propels the animal forward.

Food and feeding. An internal mucous sheet, secreted by the endostyle, allows ascidians and thaliaceans to utilize a variety of organisms, especially small plants (phytoplankton) as their food source (see below *Internal features: Digestion, nutrition, and excretion*). Some trap small animals. The feeding mechanism is different in appendicularians. Glands on the surface of the body secrete a complex house made up of mucus, which surrounds the animal. Undulations of the tail produce a feeding current that draws water into the house and through a fine sheet of mucus, which serves as a net to filter the food. Appendicularians feed on microscopic organisms (nannoplankton).

Associations. Tunicates often are hosts for various parasitic animals. Some tunicates, especially in the tropics, live symbiotically with unicellular plants and blue-green algae that may provide them with a supply of food.

FORM AND FUNCTION

General features. A tunicate tadpole larva contains several chordate features, such as the notochord, dorsal nerve cord, and tail. These features are lost, however, as the larva metamorphoses into the adult form (Figure 1). The tunicate larva has special organs of sense and attachment, which it uses to find and occupy a suitable habitat. Once settled, the larval features regress and considerable changes in size and proportion of parts take place. Larvae attach at the anterior end (under the mouth) and, by differential growth, the larva loses most of the chordate features. For example, the notochord, nerve cord, and most of the tail are resorbed. The area between the mouth and the point of attachment grows rapidly until the mouth comes to be directed away from the point of attachment, which now becomes the posterior end of the animal. The atrium usually forms from a pair of pouches that grow inward and fuse into a single cavity that opens near the mouth on what is technically the dorsal area of the body.

Characteristic features

External features. A solitary tunicate has two major openings, or siphons, on the surface away from the area of attachment: a branchial aperture, through which water enters the body, and an atrial aperture, through which water, wastes, and gametes leave. The animal is covered with a thick tunic, which consists of some cells, blood vessels, and a secretion of a variety of proteins and carbohydrates,

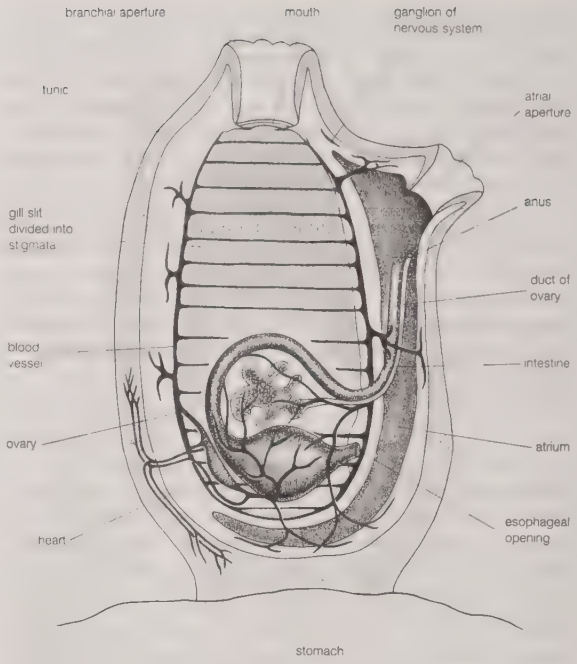

Figure 1: Anatomy of *Ascidia*, a solitary tunicate.
After a drawing by W A Herdman, 1882

including cellulose, which, although abundant in plants, is unusual in animals.

Some solitary, sessile ascidians are stalked, and budding commonly occurs by growth at the base of the animal. In "social" colonial ascidians the zooids are relatively independent, whereas in "compound" colonial ascidians budding gives rise to a colony in which the zooids are embedded in a common tunic. Several zooids may share a single, common cloacal aperture through which water exits, but each zooid has its own branchial aperture through which water enters.

Internal features. *Skeleton, tissues, and muscles.* The tunic functions to some extent as an external skeleton that supports and protects the body. Additional support is provided by body fluids and connective tissue. Firm proteinaceous rods also may support the branchial apparatus.

Although musculature is poorly developed in tunicates, there are muscles that retract the body and constrict the atrial cavity, allowing it to eject water. In dolioloids and salps, these muscles have become modified so as to produce the characteristic jet propulsion.

Nervous system and organs of sensation. In the tadpole larvae and appendicularians, the dorsal nerve cord is well developed. At the anterior end there are usually sensory structures, which detect light and orient the animal to gravity. Similar sensory structures can be found in adult thaliaceans. Special organs of sense are otherwise poorly developed. When the larva metamorphoses into an adult, the original nervous system and sensory organs degenerate, leaving a single ganglion between the oral and atrial openings. Nerves grow to the various organs of the body from this ganglion.

Sensory structures

Digestion, nutrition, and excretion. In ascidians and thaliaceans the beating action of cilia creates a water current. As the water is driven from the branchial sac into the atrial cavity, a sheet of mucus, secreted by the endostyle, traps a variety of very small organisms suspended in the water current, especially small plants (phytoplankton). The mucus is rolled into a cord and then conveyed to the intestine, where it is digested and absorbed. A stomach and glands may be present. The intestine ends as an anus in the atrium below the atrial aperture. Wastes are ejected through this aperture in a stream of water.

Metabolic wastes, such as the breakdown products of protein, are excreted at various parts of the body, including the surfaces of the gills and the intestine, and sometimes by a discrete kidney. In many cases wastes are stored as solid deposits rather than being excreted from the body as they are produced.

Respiration. Gas exchange occurs in the gill and also across various other body surfaces, such as the lining of the atrium.

Water/vascular system. Tunicates do not have the well-developed secondary body cavity (coelom) of other chordates, but traces of one perhaps are represented by cavities around the heart and by an extension of the gut called the epicardium around some of the internal organs. The body cavities are considered to be a part of the circulatory system. There are a heart and some large blood vessels but no tiny capillaries. The tunicate heart is unusual in that it periodically reverses the direction in which it pumps the blood, but the reasons for this are unknown. There are many different cell types in the blood.

Hormones. A variety of possible endocrine organs help to coordinate feeding and reproduction. Various chemical substances are known to act as hormones in vertebrates; however, their exact role in the tunicates themselves is uncertain.

Features of defense and aggression. The tunic provides ascidians with some defense. They also may be protected by chemicals that make them distasteful to predators. Appendicularians are small and therefore difficult to see. If attacked, they can escape from the house and form a new one. Thaliaceans are protected somewhat by transparency and can evade some predators by quickly ejecting a jet stream of water. They have well-developed light-producing organs, which may help to deter predators.

EVOLUTION AND PALEONTOLOGY

Because they are soft-bodied animals, tunicates have left little fossil record apart from the hard mineral particles, called spicules, that are found in the tunics of some species. A single lineage within the class Ascidiacea, or perhaps a lineage of ascidian-like tunicates that branched off prior to the common ancestor of the Ascidiacea, probably gave rise to the other two classes. Embryonic thaliaceans show indications of having been derived from attached colonies. The pyrosomes, which resemble the colonies of some ascidians, evidently branched off first within the class Thaliacea and may not even be related to the doliolids and salps. Appendicularians may have evolved from a more typical tunicate after early attainment of sexual maturity and the loss of the adult stage (*i.e.,* by paedomorphosis, retention of some juvenile features in the adult). There is some evidence that appendicularians are an early branch whose features are ancestral rather than specialized. Within the Ascidiacea, the common ancestor is generally thought to have been a solitary animal that did not reproduce by budding. The basis for this theory is that many ascidians do not bud, and the different patterns of budding that characterize distinct groups suggest independent origins. Evolution within the group has involved considerable elaboration of complex colonies, with the zooids themselves tending to become smaller and simpler in structure. There is a distinct trend toward parental care, especially in the colonial forms.

CLASSIFICATION

Annotated classification.

SUBPHYLUM TUNICATA (or UROCHORDATA)
Chordates with notochord restricted to the tail and, except in Appendicularia, only in tadpole larva; body covered with a tunic containing cellulose; atrium, except in Appendicularia, present and opening dorsally; heart present; coelom reduced; no clear traces of segmentation; about 1,300 species.

Class Ascidiacea (sea squirts)
Fixed as adults, solitary or colonial, oral and atrial apertures usually directed away from substrate.

Subclass Enterogona
Gonads unpaired, either within or behind intestinal loop; body may be divided into thorax and abdomen.

Order Aplousobranchia. Gills simple, unfolded and without longitudinal vessels or bars; digestive tract and genital organs in posterior part of body.

Order Phlebobranchia. Gills with longitudinal vessels and bars, without folds; gonads on one side, near digestive tract.

Subclass Pleurogona
Gonads and digestive tract by side of gill.

Order Stolidobranchia. Gill with longitudinal vessels, folded.

Class Appendicularia (or **Larvacea**)
Adult small, pelagic, retaining larval notochord and tail; pharynx simple with two gill openings; no distinct atrium.

Class Thaliacea
Pelagic forms; atrial aperture directed toward the rear of each zooid; asexual buds form from a ventral stolon.

Order Pyrosomida. Zooids embedded in a tube open at one end.

Order Doliolida. Complex alternation of generations between a solitary, asexually and sexually reproducing gonozooid and colonial, asexually reproducing oozooids; gill with several to many stigmata.

Order Salpida. Complex alternation of generations between solitary, asexually reproducing oozooids and aggregated, sexually reproducing gonozooids. Pharynx leads to atrium by a single pair of slitlike openings.

Critical appraisal. The above classification only approximates a natural, or genealogical, system. It is ambiguous with respect to the relationships of the three classes. Some authors put the class Appendicularia together with the class Thaliacea as Pelagotunicata, suggesting one possible relationship. Within the class Ascidiacea the system suggests that the original condition was that of the order Phelebobranchia and that the gill became simplified in a second group (order Aplousobranchia) and more complicated in a third (order Stolidobranchia). The Phlebobranchia, therefore, are not a single lineage but a grade, with some lineages close relatives of Aplousobranchia, others close relatives of Stolidobranchia, and others perhaps early branches. A change from simple to complex gills is also possible. Within the class Thaliacea the orders Doliolida and Salpida perhaps have a closer common ancestry with each other than with the order Pyrosomida, but this is not clear from the arrangement. Older systems were artificial rather than genealogical and often put all of the colonial forms together, even though it was known that colonial structure evolved more than once.

Cephalochordates

The cephalochordates, or lancelets, are small, fishlike marine invertebrates that probably are the closest living relatives of the vertebrates. There are about 20 species in two families, each with a single genus. *Branchiostoma* was formerly called *Amphioxus,* a name that is retained as an informal term (Figure 2). The other genus is *Epigonichthys,* also called *Asymmetron.* The genus *Asymmetron* is sometimes retained for some species.

GENERAL FEATURES

Size and range of diversity of structure. Adult lancelets reach a length of about six to seven centimetres (2.5 inches). There is little structural diversity within the group, the main difference between the two families being the restriction of the gonads to one side of the body in *Epigonichthys.*

Importance. Although edible, lancelets are never sufficiently abundant to constitute a significant source of food to humans or an important part of the food chain in nature. Rather, their significance has to do with their place in evolution, as invertebrates transitional to vertebrates providing clues for the history of human lineage. This connection was first shown by the Russian zoologist Aleksandr Kowalevsky in 1867 in embryological evidence that was influential in establishing that evolution has in fact occurred. Lancelets have a structure that illustrates the characteristic features of chordates in simple form.

Evolutionary significance

NATURAL HISTORY

Reproduction and life cycle. Lancelet sexes are separate, and asexual reproduction does not occur. Eggs and sperm are shed directly into the water, where fertilization occurs. The early stages of development strikingly resemble those of both tunicates and vertebrates. A larva is produced that is similar in structure to the adult but is peculiarly asymmetrical (the gill slits on one side develop first), smaller, and simpler, with fewer gill slits and no atrium. The larvae spend much of their time feeding in the open

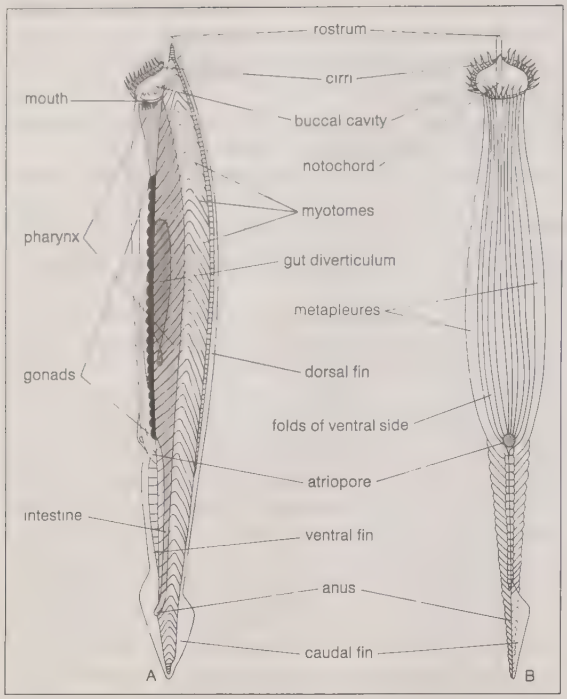

Figure 2: (A) Left lateral and (B) ventral views of the Amphioxus (*Branchiostoma lanceolatum*).
From P Grasse, *Traite de Zoologie*, vol. 11 (1948); Masson & Cie, Paris

water but can be found on the bottom. After growing and developing, they metamorphose into the adult form and complete their life history in the substrate.

Ecology and habitats. Lancelets are distributed throughout the world along tropical and temperate coasts. They inhabit soft bottoms ranging from sand to coarse shelly sand or gravel in shallow coastal water. Lancelets lie buried beneath this substrate, often with their mouths protruding above the surface, allowing them to take in water laden with food. In China, lancelets are sometimes eaten and even support a small fishing industry.

Food, feeding, and movement. Lancelets can swim both forward and backward and can move rapidly through the gravel in which they live. Their behaviour is simple, largely being a matter of locating the proper habitat and escaping from predators. Larvae filter small organisms out of the water; at the time when they metamorphose into the adult, they also feed upon coarser materials deposited on the bottom. The adults filter small organisms from the overlying water by drawing a current into the mouth. The tentacle-like cirri around the mouth form a grid that keeps out sand and other large particles.

FORM AND FUNCTION

General features. The lancelets are also called cephalochordates (Greek: *kephale,* "head") because the notochord extends from near the tip of the tail to well into the anterior of the body. Because they do not have the braincase, or cranium, of a vertebrate, lancelets are often called acraniates. The pharynx, with its many gill slits, is surrounded by the atrium, a large cavity with a single exit (the atriopore) on the lower surface of the body. The atrium protects the gills. Tunicates also have an atrium, but its evolution is probably independent of that of the cephalochordrate atrium.

Acraniates

The bodies of lancelets, like those of fishes and other vertebrates, are largely made up of serially repeated units (segments) that include blocks of muscles called metameres. This segmentation also extends to the nerves that supply the myotomes and to some body cavities, excretory structures, and other parts. Segmentation is thought to provide more effective body coordination during locomotion. The segments of vertebrates and cephalochordates are so similar that they were almost certainly present in the common ancestor of the two groups. Tunicates and hemichordates have no clear indications of ever having possessed segments. Segments occur in other animals, including annelid worms and arthropods, but these segments have a different composition and probably a separate evolutionary origin.

A distinct "secondary" body cavity (coelom), like that which contains the internal organs in vertebrates and many other animals, is well developed and forms a system of cavities and spaces. Like the coelom of hemichordates, echinoderms, and a few other animals, it develops as outpouchings in the gut of the embryo.

External features. Lancelets are steamlined animals. A dorsal fin extends along the upper surface of the body and continues as a caudal fin around a tail and as a ventral fin to an atrium on the lower surface. Paired fins are absent, but metapleural folds along the sides of the body suggest precursors of paired fins. The tip of the body projects slightly above and in front of the mouth, which is surrounded by a funnellike oral hood that bears the cirri. The anus opens well behind the atriopore, on the left side of the ventral fin. The general body surface is covered by a smooth cuticle layer.

Fins

Internal features. *Skeleton, tissues, and muscles.* The notochord extends virtually the entire length of the body and provides much of its support. It has a firm sheath and a core made up of a single series of cells that contains muscle fibres. These fibres probably maintain the stiffness of the notochord, the main role of which is keeping the body from shortening when the animal swims. The gills, fins, and cirri also contain stiff, supportive rods.

The main body musculature occurs in horizontal chevron-shaped blocks of muscle (myotomes) like those of fishes. This arrangement allows the muscles to pull more effectively in producing a side-to-side movement of the body in swimming. The remaining muscles are quite small and associated largely with feeding and the movement of internal organs.

Nervous system and organs of sensation. The cephalochordate nervous system is simple. The main nerve cord, which is single and hollow as in all chordates, has a slight swelling at the front that barely qualifies as a brain. Nerves from the main nerve cord occur in groups that roughly compare to those of vertebrates in arrangement and in the regions supplied. There are small eyelike organs in the nerve cord that can detect the direction of light and changes in its intensity. Various areas of the body surface, including some near the mouth, detect chemicals in the water and thereby aid in feeding.

Digestion and excretion. Lancelets are filter feeders that extract small particles suspended in the water. The mouth is covered by an oral hood, the edges of which form the buccal cirri. The cephalochordate commonly is buried in the substrate and positions its mouth above the surface of the sand. During feeding, the cirri form a kind of grid that keeps out large particles. Water is drawn into the mouth by the beating action of cilia on the gills. The pharynx is a large section of the gut just behind the mouth, extending about two-thirds the length of the body, with many narrow gill slits. The water current enters the pharynx, passes through the gill basket to the atrium, and leaves the body through the atriopore. On the floor of the pharynx, between the left and right series of gill slits, an endostyle secretes a sheet of mucus that moves upward along the gills and traps food particles suspended in the water current. The mucus is rolled up and transported to the intestine, where food is digested and absorbed. There is no distinct stomach. The intestine is straight, except for a blind outpouching called the caecum, which has, on the basis of position, been compared to the liver and pancreas of vertebrates. It extends forward along the right side of the pharynx.

Filter feeders

Lancelets have unique excretory structures called solenocytes, which occur only in some distantly related animals, such as annelids.

Respiration. The gill is largely a feeding organ, but it also serves for the exchange of gases in respiration. After the water has passed through the gill slits, it reaches the atrium and exits through the atriopore. Excretory products and eggs and sperm also exit the body through this opening.

Gill slits

Circulatory system. The general pattern of blood circu-

lation through vessels and tissues in cephalochordates is strikingly like that of vertebrates, although simpler. The most notable difference is that cephalochordates lack a heart. Blood is forced through the closed system by contractile blood vessels (especially one called the ventral aorta) and by blood vessels of the gills. Blood passes forward from the rear of the body to the ventral aorta, which is located beneath the endostyle, and then branches upward through vessels in the gills. Most of the blood then passes toward the rear of the animal, some of it moving through capillaries in the intestine and taking up food. From the posterior end of the body, blood passes forward and then makes a detour through capillaries in the caecum, much as it does through the liver of lower vertebrates, back to the ventral aorta. There are no corpuscles in the blood.

Hormones. The endostyle takes up iodine and forms thyroxine, an important hormone produced by the vertebrate thyroid gland. This homology is interpreted as a step in the evolution of the thyroid from the endostyle. It is not certain what role thyroxine plays in the physiology of the lancelets themselves, however.

EVOLUTION AND PALEONTOLOGY

Soft-bodied animals such as lancelets rarely have a good fossil record. A few fossils have been interpreted as cephalochordates, but few of these determinations are well founded. A good possibility is *Pikaia,* a fossil discovered in the Burgess Shale (Middle Cambrian, about 530 million years old). *Pikaia* has myotomes and what looks like a notochord, indicating that it is a chordate, but only its shape suggests that it is a lancelet rather than a fish.

The cephalochordates make plausible models for the common ancestor of the chordates and for precursors to vertebrates. They evidently represent a collateral branch on the vertebrate lineage that has been somewhat modified since common ancestry, however, and should not be thought of as a human ancestor. Several features unique to cephalochordates and vertebrates suggest that they are "sister groups" more closely related to each other than either is to other chordates. These features include the segmented musculature and its innervation, the pattern of circulation, and several biochemical features. The atrium is thought to have evolved independently in cephalochordates and tunicates; hence there is little evidence for the two forming a single lineage.

Whether the ancestral chordate was more like a cephalochordate or a tunicate is debatable, because features absent in tunicates could mean that they never have been present or could mean that they have been lost. Some authors have argued that the simplicity of cephalochordates is due to degeneration, but there are no clear indications that this is true.

CLASSIFICATION

SUBPHYLUM CEPHALOCHORDATA
Notochord extends anterior to dorsal nerve cord; atrium ventral; segments and coelom well developed; no heart; no paired fins.

Family Branchiostomatidae
Double row of gonads; *Branchiostoma.*

Family Epigonichthyidae
Gonads on right side of body only; *Epigonichthys.*

(M.T.G.)

Vertebrates

The chordate subphylum Vertebrata is one of the best known of all groups of animals. Its members include the classes Agnatha, Chondrichthyes, and Osteichthyes (all fishes); Amphibia (amphibians); Reptilia (reptiles); Aves (birds); and Mammalia (mammals).

GENERAL FEATURES

Characteristic features

Although the vertebral column is perhaps the most obvious vertebrate feature, it was not present in the first vertebrates, which probably had only a notochord. The vertebrate has a distinct head, with a differentiated tubular brain and three pairs of sense organs (nasal, optic, and otic). The body is divided into trunk and tail regions. The presence of pharyngeal slits with gills indicates a relatively high metabolic rate. A well-developed notochord enclosed in perichordal connective tissue, with a tubular spinal cord in a connective tissue canal above it, is flanked by a number of segmented muscle masses. A sensory ganglion develops on the dorsal root of the spinal nerve, and segmental autonomic ganglia grow below the notochord. The trunk region is filled with a large, bilateral body cavity (coelom) with contained viscera, and this coelom extends anteriorly into the visceral arches. A digestive system consists of an esophagus extending from the pharynx to the stomach and a gut from the stomach to the anus. A distinct heart, anteroventral to the liver, is enclosed in a pericardial sac. A basic pattern of closed circulatory vessels is largely preserved in most living forms. Unique, bilateral kidneys lie retroperitoneally (dorsal to the main body cavity) and serve blood maintenance and excretory functions. Reproductive organs are formed from tissue adjacent to the kidneys; this original close association is attested by the tubular connections seen in males of living forms. The ducts of the excretory organs open through the body wall into a cloacal chamber, as does the anus of the digestive tract. Reproductive cells are shed through nearby abdominal pores or through special ducts. A muscular tail continues the axial musculature of the trunk.

Distribution

Approximately 45,000 living species constitute the vertebrates. Species of several classes are found from the high Arctic or Antarctic to the tropics around the Earth; they are missing only from interior Antarctica and Greenland and from the North Polar ice pack. In size, vertebrates range from minute fishes to elephants and whales (of up to 100 tons), the largest animals ever to have existed. Vertebrates are adapted to life underground, on the surface, and in the air. They feed upon plants, invertebrate animals, and one another. Vertebrate faunas are important to humans for food and recreation.

NATURAL HISTORY

In order to give a broad and comparative view of their life histories, the vertebrates are subdivided here into major groups based on morphology: the cyclostomes (jawless fishes), the chondrichthyes (cartilaginous fishes), the teleostomes (bony fishes), and the tetrapods.

Hagfishes and lampreys

The cyclostomes. The cyclostomes include two classes of living, jawless fishes (agnathous)—Petromyzontiformes (lamprey eels) and Myxiniformes (hagfishes). The hagfishes are totally marine, often living in deep waters associated with muddy bottoms. The lampreys may be marine as adults but spawn in fresh waters, where the larvae spend some time before metamorphosing to the adult. Some lampreys live entirely in fresh water and may change only slightly in habit as a result of metamorphosis. Without lateral fins, lampreys swim by undulations of the body and can control direction only for short distances.

The living agnaths are predatory, the lampreys being well known for attacking salmonoid fishes. The lamprey attaches to its prey using its round, suctorial mouth, and it rasps a hole through the outer tissues using a tongue armed with keratinized teeth. It suctions off bits of tissue, blood, and body fluids. The hagfishes feed somewhat similarly, but on a variety of prey—invertebrates (worms and soft-bodied forms) and dead fishes.

The lampreys produce small eggs, which develop directly into larvae that burrow into the muddy bottom of the stream. With its mouth at the surface of the mud, the larva filter feeds until large enough to metamorphose and swim off as a small adult. In contrast, the hagfishes produce relatively large encapsulated, yolky eggs up to two centimetres in length. When laid, these eggs attach to any available object by terminal hooks. The encased egg develops more or less directly into a miniature adult.

Cartilaginous fishes

The chondrichthyes. The sharks, rays, and chimaerids are usually marine, but some sharks have entered fresh waters (the Amazon) or even live there permanently (Lake Nicaragua). In size, sharks range from the whale shark, nearly 10 metres in length, to rather small species, three centimetres in length. They usually weigh 25 to 200 kilograms (55 to 440 pounds). Sharks are predatory animals. Some large shark species (basking and whale sharks) fil-

ter feed on small crustaceans. Herbivorus sharks are unknown. Sharks swim by undulations of the tail, but rays "fly" through the water by undulations of the pectoral fins. Most species occur in near-shore waters, but some range widely throughout the oceans. A few are found in deep water.

A few sharks produce live young (viviparous) after internal fertilization. The posterior angle of the male's pelvic fins are modified into a clasper, which acts as an intromittent organ in copulating with the female. Most sharks lay large yolky, encapsulated eggs with hooks for attachment. The young develop directly and begin life as miniature adults. The young that develop in the mother's uterus obtain nutrients from the large yolk sac until they are born alive. In a few cases, the uterine wall secretes nutrients.

The teleostome, or osteichthyian, fishes (those having an internal bony skeleton) can be divided into two groups: the subclasses Actinopterygii (ray-finned fishes) and Sarcopterygii (lobe-finned fishes). The latter group includes the lungfishes, which live in marshes, ponds, or streams, and are frequent air breathers. They lay fairly large eggs, with a limited amount of yolk, that are enclosed in jelly coats like those of an amphibian. The eggs develop into small fishes that feed on live prey. The larvae of the African lungfish have external gills to supplement oxygen intake.

Bony fishes

The teleostomes. Actinopterygian fishes are the common bony fishes of modern aquatic environments. They range in size from fishes that are only millimetres in size to those two or more metres (6.6 or more feet) in length, weighing 500 kilograms or more. Large species (sturgeons) are found in fresh waters (several other large species are found in the Amazon) as well as in marine environments. The diet may include plants, animals, and carrion. Most species are midwater swimmers, but many spend much time lying on the bottom. Tail, pectoral, and even dorsal fins are used in swimming. Reproduction in this group is by way of large numbers of small eggs, which produce small larvae or develop directly to the adult.

The tetrapods. The tetrapods live primarily on land and are rather similar in habit. Members include the amphibians, reptiles, birds, and mammals. Amphibians are widespread in the warmer parts of the continents, being absent only in the far north and in the Antarctic. Three orders are recognized: Candata (the salamanders), the frogs and toads (Anura, or Salientia), and the Apoda or Gymnophiona (caecilians). Modification takes many forms, from the moist glandular skin (some scale remnants persist in apodans) to the loss of many of the bones of the skull. Like their ancestors, amphibians are cold-blooded and tend to be aquatic or limited to moist surroundings. Salamanders are seemingly the least modified in body form. They do not actively pursue prey and at best are only marginal swimmers. In swimming or crawling, the salamander's body and tail undulate. Frogs and toads hop using hind-limb propulsion and the forelimbs as body props. This dominance of the hind limb in locomotion is best seen in swimming when the forelimbs are drawn back against the body. In contrast to the salamanders and frogs, the burrowing, wormlike apodans are without limbs.

Amphibians usually trap food using a tongue that can be shot out of the mouth, or they use the mouth itself to grasp and ingest food. There is great variation in foods; only the larvae of frogs and toads appear to be plant feeders, a specialization that is reflected in the highly modified jaws and guts of the tadpoles.

Amphibians have retained a simple egg cell with a gelatinous cover. The eggs are laid in ponds, streams, or even in damp places high in trees, usually in great numbers. Fertilized eggs develop into free-swimming larvae, which then metamorphose to adults, but in highly specialized forms.

Reptiles

The class Reptilia retains many of the structural characteristics of the ancestral amphibian. While most reptiles are carnivorous, feeding on other organisms, a few are herbivorous (*e.g.*, tortoises). As cold-blooded animals, reptiles tend to be limited to temperate and tropical areas, but, where found, they are relatively common, although not as large or conspicuous as birds or mammals. Most reptiles are terrestrial, but a few are aquatic. As basic tetrapods, reptiles move about by creeping or swimming in a fashion similar to amphibians. Some reptiles, however, can lift the body from the ground and run rapidly either in a quadrupedal or bipedal fashion. Reptiles lay relatively large, shelled eggs. In a few instances, the eggs and young are cared for by the female; in others, the young are born alive (ovovivipary).

Birds are warm-blooded, and, although most are capable of flight, others are sedentary and some are flightless. Like their relatives the reptiles, birds lay shelled eggs that differ largely in the amount of calcification (hardening) of the shell. The young are usually cared for in a nest until they are capable of flight and self-feeding, but some birds hatch in a well-developed state that allows them to begin feeding immediately or even take flight. The megapods lay their eggs in mounds of rotting vegetation, which supplies the heat for incubation. (Nesting activities similar to those of some birds are seen in the crocodilians.)

Mammals

The mammals range in size from tiny shrews or small bats weighing only a few grams to the largest known animals, the whales. Most mammals are terrestrial, feeding on both animal and vegetable matter, but a few are partially aquatic or entirely so, as in the case of the whales or porpoises. Mammals move about in a great variety of ways: burrowing, bipedal or tetrapedal running, flying, or swimming. Reproduction in mammals is usually viviparous, the young developing in the uterus, where nutritive materials are made available through an allantoic placenta or, in a few cases, a yolk sac. The fertilized egg develops directly into the adult. The monotremes (platypus and echidna) differ from other mammals in that they lay eggs which hatch, and the relatively undeveloped young are carried in a pouch or kept in a nest; the growing young lap up a milk nutrient fluid exuded from the belly of the mother.

FORM AND FUNCTION

External features. The evolution of the notochord, dorsal nerve tube, and pharyngeal slits in chordate structure suggests improved swimming capability and probably greater ability to capture prey. Specialization in the vertebrate for the active capture of larger prey is evident both in the structure of the mouth and in the relatively simple structure of the pharynx, with its strong gill development. Specialization for feeding is again seen in the two basic groups of vertebrates, the agnathans and gnathostomes. Swimming adaptations are also numerous and involve variations both in body form and in medial fins and the two pairs of lateral fins.

Exoskeleton and endoskeleton

Internal features. *The skeletal system.* Support and protection are provided by the exoskeletal and endoskeletal divisions of the skeletal system. The exoskeleton, when present, is basically protective but functions in tooth support in the mouth region. The endoskeleton protects the brain and spinal cord and assists primarily with locomotion in the trunk and tail regions. The endoskeleton begins as cartilage and may remain so or may develop into bone. The cartilaginous endoskeleton, found in the shark or chimaerid, is usually calcified so as to be stiffer and stronger. Bone is distinctive but highly variable; some types of bone contain cells, others do not, or the bone may be laminar, spongy, or arranged in sheathing layers around blood channels.

Tissues and muscles. Tissue development in the vertebrate is unique in its complexity; tissues in the strict sense (defined as a mass or sheet of similar cells with a similar function), however, do not exist. The simplest situation is seen in the epidermis, but even here there is a layered system in which different cell types provide different functions (such as protection and secretion). The stratified epithelium of the vertebrate is highly characteristic of that group (a similar one is seen in only one invertebrate group, the class Chaetognatha).

Other tissues of the vertebrate are more complex than the epithelium. For example, skeletal muscle consists not only of striated muscle fibres but also of connective tissue, which binds it together and attaches it by way of tendons. This contractible tissue includes nerves and blood vessels and their contained blood. Skeletal muscles thus appear as simple organs, just as do the smooth muscles in the

wall of the gut or the iris muscles of the eye. Such unique histological complexity runs through the entire body of the vertebrate.

Nervous system and organs of sensation. The dorsal position, tubular structure, and epidermal origin of the central nervous system are definitive of the chordates, although some may see similarities with the hemichordates. The sensory structures are distinctive of the chordates and include the paired nasal, optic, and otic organs (along with the strongly differentiated head).

Sensory structures

The nasal vesicle is variously open to the environment, and its sensory cells, as chemical receptors, are not unlike those in the taste buds of the mouth. The eye is the most complex organ of the head and is a lateral outpocketing of the anterior end of the brain tube. Later it acquires a lens of epidermal origin. The act of focusing the eye (accommodation) shows extensive adaptive variation among the different groups of vertebrates.

The otic vesicle starts from a simple sac formed by the invagination of an ectodermal placode. These developmental changes also include the changes of innervation. Whereas the original structure was basically an equilibrium adaptation, other functions, such as an awareness of movement or the sensation of the proximity of prey, developed.

The lateral-line system of canals and sensory organs is a unique vertebrate feature. The elements of this system are found on the head as well as the body. This system is related to the ear and presumably at its origin served a similar function. This system is lost in terrestrial vertebrate forms.

The digestive system. The digestive system of the vertebrate is distinctive in its structure but not in its function. The mouth and pharynx can be considered as parts of this system; the latter as an expanded cavity in the head is unmatched in any other group. The stomach and gut have been discussed above.

Diverticulum

Presumably the original condition of the digestive glands was that of a ventral diverticulum which may have received the food mass into its cavity. This diverticulum, matched by the diverticulum seen in the amphioxus or the "intestine" of the tunicate, produced the secretions (bile-like and enzymes) of both liver and pancreas. Through time, the liver gradually differentiated from the pancreas. The size and separation of the liver from the gut suggest its separate blood and metabolic activities. The most obvious by-product of the liver, bile, necessitated the formation of a gall bladder and a duct connection with the gut. The pancreas, in contrast, continued to produce digestive enzymes, but its secretory cells were no longer in direct contact with the food mass. Because the pancreas was only a partial source of intestinal digestive enzymes, it was sometimes reduced in size and enclosed in the gut wall itself (agnaths) or dispersed as tiny bits of tissue in the mesentary supporting the gut (actinopterygians).

The excretory system. The excretory system is unique in its nephrons, which filter the blood in the glomeruli and remove a variety of wastes from the body through selective secretion and reabsorption. In the shark or the coelacanth *Latimeria,* urea is used to raise the osmotic pressure of the blood to that of the marine habitat, thus saving these organisms considerable metabolic energy. The large intestine (sometimes centred in a rectal gland) acts as an auxiliary excretory organ, as do also the gills of fishes or the sweat glands of mammals.

Respiration and gas exchange. Respiration, like excretion, involves specialized body structures, such as lungs or gills, but also can involve other areas, such as the skin itself. Respiration involves exchange of gases both between the body of the organism and the environment and between the blood system and the body tissues. It also involves cellular respiration where oxygen is used and carbon dioxide is produced. There is nothing characteristic of the vertebrate in this functional area; even the hemoglobin of the blood is suggested in the respiratory pigments of other animals.

The circulatory system. The circulatory system of vertebrates is closed in that fluids course through vessels, but there is free movement of cells in and out of blood. Some leukocyte (white blood cell) movement out of the capillaries and fluid leakage are observed in all tissues. Blood tissues are distinctive in the range of specialized cells, although these vary in detail among animals. The immune function of the blood is best developed in the vertebrate.

The endocrine system. The endocrine system is characterized by its separate organs. The occurrence of a pituitary or a thyroid gland is suggestive of the evolutionary change and specialization that took place within this group. The relatively unspecialized nature of some parts of this system is seen in certain scattered cells in the gut wall or even the clumps of islet cells of the pancreas.

EVOLUTION AND PALEONTOLOGY

The knowledge of vertebrates as revealed by fossils has grown rapidly during the past few decades, but there is much still to be discovered. The ancestral vertebrate (protovertebrate) has been sought for more than 100 years, and the likelihood of finding it today is not much greater than in the past. It can be assumed that the protovertebrate was small and soft-bodied, two factors that suggest the improbability of finding a fossilized form in a recognizable condition. There are Cambrian fossils that have been suggested to be fossil cephalochordates and there are scales of agnath fishes, but the first type of fossil is too simple and the second already too complex to explain the transition.

(M.T.J.)

CLASSIFICATION

Annotated classification.

SUBPHYLUM VERTEBRATA (or **CRANIATA**)
Bilaterally symmetrical; internal skeletal support with skull enclosing a highly developed brain and a vertebral column and nerve cord; paired, jointed appendages; skin; advanced organ systems; sense organs concentrated in head.

Class Agnatha (hagfishes, lampreys)
Primitive; jawless; paired fins are poorly developed or lacking; rasping tongue; notochord without bone; skin is soft, glandular, and slimy; true gill arches absent; marine habitat.

Class Placodermi (placoderms)
†Extinct; fishlike; jaws supported by both cranium and hyoid arch (amphistylic); partly ossified cranium; primitive; head and trunk have armour that is jointed at the neck; pelvic fins present or absent; pectoral fins or finlike structures often present; gill arches.

Class Chondrichthyes (sharks, rays, and skates)
Cartilaginous fishes; jaws; paired fins; no swim bladder; pelvic fins in males often modified to form claspers; gill arches internal to gills; reduced notochord; lateral-line system; paired nostrils; internal nares absent; separate sexes; internal fertilization and direct development; oviparous, ovoviviparous, or viviparous.

Subclass Elasmobranchii (sharks and rays)
Numerous teeth derived of placoid scales; 5 to 7 gill clefts; operculum absent; cloaca; upper jaw not fused with braincase; dorsal fin nonerectile; with spiracles; worldwide distribution.

Subclass Holocephali (chimeras)
Teeth fused to bony plates; no scales; 4 gill pairs under 1 gill opening on each side; no cloaca; no spiracles; operculum present; upper jaw fused to braincase; dorsal fin erectile; whiplike tail; claspers present in males; temperate marine freshwater.

Class Osteichthyes (bony fishes)
Jaws; partly or fully ossified skeleton; usually a swim bladder; paired fins; gills covered by a bony operculum; scales; paired nostrils with or without internal nares; lateral-line system; mostly oviparous with external fertilization; some ovoviviparous or viviparous.

Subclass Actinopterygii (ray-finned fishes)
Generally lack choanae; no fleshy base to paired fins; no internal nares; air sacs usually function as swim bladder; skeleton usually well ossified.

Subclass Sarcopterygii (lobe-finned fishes)
Usually possess a choana; paired fins with a fleshy base over a bony skeleton; persisting notochord; 2 dorsal fins; nares are internal.

Class Amphibia
Cold-blooded; respire by lungs, gills, skin, or mouth lining; larval stage in water or in egg; skin is usually moist with mucous glands and without scales; tetrapods; freshwater and terrestrial; paired appendages are legs; 10 pairs of cranial nerves; separate sexes; external fertilization with development into tadpole larvae; some have internal development, ovoviviparous or viviparous.

Order Aponda (or *Gymnophiona;* caecilians). Wormlike; no limbs or girdles; compact skull; lidless, minute eyes; persistent notochord; tail; scales present in some species.

Order Anura (or *Salientia;* frogs and toads). Tailless; elongated hind limbs modified for jumping; larvae lack true teeth and external gills.

Order Caudata (or *Urodela;* salamanders). Tail; limbs normal; many skeletal elements cartilaginous; larvae with true teeth and external gills.

Class Reptilia

Cold-blooded; no larval stage; breathing by lungs; well-ossified skull; dry skin; scales; no glands; 5-toed limbs; claws; 3- or 4-chambered heart with incomplete ventricle separation; 12 pairs of cranial nerves; internal fertilization, direct development; oviparous and ovoviviparous.

Subclass Anapsida (turtles, tortoises, terrapins)

No temporal skull openings; body encased in bony shell; no teeth in living members; oviparous.

Subclass Lepidosauria

No bipedal specializations; 2 complete temporal openings; complete palate; oviparous; male is without penis.

Subclass Archosauria (ruling reptiles)

Some ancient forms had bipedal locomotion; longer hind legs; semiaquatic; webbed feet; teeth in sockets; single penis; oviparous; includes extinct dinosaurs.

Subclass Synaptosauria

†Extinct; single temporal opening on area of cheek.

Subclass Ichthyopterygia

†Extinct; temporal openings high up on skull; fishlike; spindle-shaped body; high tail fin; triangular dorsal fin; paddlelike legs; marine.

Subclass Synapsida

†Extinct; mammallike; lateral temporal opening.

Class Aves

Warm-blooded; skull has only 1 condyle; front limbs primarily modified for flight; hind limbs are legs with 4 or fewer toes; body covered with feathers; scales on feet; 4-chambered heart; no teeth; horny beak; lungs with extended air sacs; 12 pairs of cranial nerves; internal fertilization; oviparous.

Subclass Archaeornithes

†Extinct; teeth in both jaws; long, feathered tail; less specialized for flight; body elongated and reptilelike; forelimb had 3 clawed digits; small brain and eyes; nonpneumatic bones.

Subclass Neornithes (true birds)

Well-developed sternum; tail is not long; no teeth; forelimbs modified to wings; teeth replaced by horny rhamphoteca over bill.

Class Mammalia

Warm-blooded; mammary glands; lower jaw is composed of 1 bone; hair; advanced brain; skin with different glands and hair; ears with 3 middle-ear bones; 12 pairs of cranial nerves; 4-chambered heart; young nourished by milk from mammary gland; internal fertilization; mostly viviparous, some oviparous.

Subclass Prototheria

Primitive; egg-laying; hair; mammary glands without nipples; pectoral girdle; separate oviducts that open into cloacal chamber that is shared with excretory ducts; oviparous.

Subclass Theria

Mammary glands with nipples; functional teeth; oviducts partly fused; with or without a cloaca; uterus and vagina; viviparous. (Ed.)

Critical appraisal. The classification of animals is presently in a state of flux. The classification presented here is traditional and conservative. Because traditional theories of taxonomy tend to be nonquantitative, various interpretations of relationships or patterns can be presented and defended.

The alternative cladistic style of taxonomy is an attempt to force taxonomy into a testable, highly objective operation. One tentative classification based in cladistics separates the vertebrates into two superclasses (Agnatha and Gnathostomata). Agnathans are jawless, while the gnathostomates encompass the remainder of the jawed vertebrates. Living agnathans are placed in the class Cyclostomata. Gnathostomates can be further divided into the epiclasses Elasmobranchiomorphi (sharks and rays) and Teleostomi (bony fishes and tetrapods). The former group are identified primarily by a cartilaginous skeleton, while the latter group have developed a bony skeleton. Two subepiclasses of the teleostomes are Ichthyopterygii (or Osteichthyes; bony fishes) and Cheiropterygii (tetrapods), the latter being further divided into the classes Amphibia, Reptilia, Aves, and Mammalia.

Although this classification includes and uses traditional taxonomic categories, their position in the hierarchy may be changed. Separation of agnath and gnathostome is opposed by those cladists who chart the origin of gnathostomes from the agnath, believing that the differences in mouth and tooth structure are a result of modification. The Gnathostomata is subdivided into the Elasmobranchiomorphi and the Teleostomi largely on the basis of mouth and tooth structure. The creation of epiclasses and subepiclasses in the alternative classification is not important in itself; the creation of a dichotomy between Ichthyopterygii and Cheiropterygii, however, is important, although from the evolutionary view it is evident that the one evolved from the other. Christianity

Founded in the 1st century AD by Jesus of Nazareth (the Christ, or the Anointed One of God), Christianity has become the largest of the world's religions. Geographically the most widely diffused of all religions, it has a constituency of more than 1,000,000,000. Its largest groups are the Roman Catholic Church, the Eastern Orthodox churches, and the Protestant churches; in addition to these churches there are several independent churches of Eastern Christianity as well as numerous sects throughout the world. See also EASTERN ORTHODOXY; ROMAN CATHOLICISM; and PROTESTANTISM.

This article first considers the nature and development of the Christian religion, its ideas, and its institutions. This is followed by an examination of several intellectual manifestations of Christianity. Finally, the position of Christianity in the world, the relations among its divisions and denominations, its missionary outreach to other peoples, and its relations with other world religions are discussed. For supporting material on various topics, see BIBLICAL LITERATURE AND ITS CRITICAL INTERPRETATION; DOCTRINES AND DOGMAS, RELIGIOUS; JESUS: THE CHRIST AND CHRISTOLOGY; RITES AND CEREMONIES, SACRED; and SACRED OFFICES AND ORDERS.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 827, and the *Index*.

The article is divided into the following sections:

THE CHURCH AND ITS HISTORY

The essence and identity of Christianity

At the very least, Christianity is the faith tradition that focuses on the figure of Jesus Christ. In this context, faith refers both to the believers' act of trust and to the content of their faith. That tradition, viewed as a system of belief and behaviour, leads people to see Christianity as one of the world religions, alongside Hinduism, Buddhism, Islām, and others.

As a tradition, Christianity is more than a system of religious belief. It also has generated a culture, a set of ideas and ways of life, practices, and artifacts that have been handed down from generation to generation through the 20 centuries since Jesus first became the object of faith. Christianity is thus both a living tradition of faith and the culture that the faith leaves behind as a kind of deposit. The agent of Christianity is the church, the community of people who make up the body of believers. Christianity may incorporate, along with such believers, their doctrines, customs, and historical episodes.

Jesus Christ as the focus of Christianity

To say that Christianity "focuses" on Jesus Christ is to say that, whatever else it comprehends, somehow it brings these realities together in reference to an ancient historic figure. Few Christians would be content to keep this reference merely historical. Although their faith tradition is historical—*i.e.*, they believe that transactions with the di-

vine do not occur in the realm of timeless ideas but among ordinary humans through the ages—the vast majority of Christians focus their faith in Jesus Christ as someone who is also a present reality. They may include many other references in their tradition and thus may speak of "God" and "human nature" or of "church" and "world," but they would not want to be nor would they be called Christian if they did not bring their eyes and attentions first and last to Jesus Christ.

While there is something simple about this focus on Jesus as the central figure, there is also something very complicated. That complexity is apparent when one tries to envision the more than 22,000 separate churches, sects, and denominations that make up the Christian faith tradition today. To project these separate bodies against the background of their development in the nations of the world is to suggest the bewildering variety. To picture people expressing their adherence to that tradition in their prayer life and cathedral-building, in their quiet worship or their strenuous efforts to change the world, is to suggest even more of the variety.

Given such complexity, it is natural that through the ages both those in the tradition and those surrounding it have made attempts at simplification. Two ways to do this have been to concentrate on the "essence" of the faith, and thus on the ideas that are integral to it, or to be concerned with the "identity" of the tradition, and thus on the boundaries of its historical experience.

Scholars in the modern world have tended to locate the focus of this faith tradition in the context of monotheistic religions. Christianity addresses the historical figure of Jesus Christ against the background of, and while seeking to remain faithful to, the experience of one God. It has consistently rejected polytheism, which allows for many gods, and atheism, which makes Jesus a purely and ordinarily human figure without divine or transcendent reference.

To monotheism as an element of the faith tradition of Christianity one may add that, with rare exceptions, Christianity refers to a plan of salvation or redemption. That is to say, the believers in the church picture themselves as in a plight from which they need rescue. For whatever reason, they have been distanced from their source in God and need to be saved. Christianity is based on a particular experience or scheme directed to the act of saving—that is, of bringing or "buying back," which is part of what redemption means, these creatures of God to their source in God. The agent of that redemption is Jesus Christ.

It is possible that through the centuries the vast majority of believers have not used the term essence to describe the central focus of their faith. The term is itself of Greek origin and thus represents only one part of the tradition, one element in the terms that have gone into making up Christianity. The search for an essence may be more urgent for philosophers, theologians (who interpret the language of the believing community), or historians than it is for the regular believers who do not share the burden of scholars. Essence refers to those qualities that give something its identity and are at the centre of what makes that thing different from everything else. To Greek philosophers it meant something intrinsic to and inherent in a thing or category of things, which gave it its character and thus separated it from everything of different character. Thus Jesus Christ belongs to the essential character of Christianity and gives it identity in the same way that Buddha does for Buddhism.

The definition of essence

If the mass of people do not have the scholar's problem of defining the essence of Christianity, in practice they must come to terms with what the word essence implies. Whether they are engaged in being saved or redeemed on the one hand, or thinking and speaking about that redemption, its agent, and its meaning on the other, they are concentrating on the essence of their experience. Those who have concentrated from within the faith tradition have also helped to give it its identity. It is not possible to speak of the essence of a historical tradition without referring to how its ideal qualities have been discussed through the ages. Yet one can take up the separate subjects of essence and identity in sequence, being always aware of how they interrelate.

HISTORICAL VIEWS OF THE ESSENCE

Early views. The earliest members of the Christian faith tradition were Jews, as was Jesus himself, and thus they stood in the faith tradition inherited by Hebrew people in Israel (and lands to which they had been taken as captives in exile). They were monotheists, devoted to the God of Israel. When they made claims that Jesus was divine, it was part of their task to make their witness in ways that would not challenge monotheism.

Insofar as they began to separate or be separated from Judaism, which did not accept Jesus as Christ, these earliest Christians not only experienced salvation but also expressed certain ideas about the one on whom their faith focused. As with other religious people, they became involved in a search for truth. God, in the very nature of things, was necessarily the final Truth. But an early reference, preserved in the Gospel According to John, finds Jesus referring to himself not only as "the way" and "the life" but also as "the Truth." Roughly, this meant "all the reality there is" and was a reference to Jesus' participation in the reality of the one God.

From the beginning there were Christians who may not have seen Jesus as the Truth, or as a unique participant in the reality of God. There have been "humanist" devotees of Jesus, modernist adapters of the truth about the Christ; but even in the act of adapting him to humanist concepts in their day they have contributed to the debate of the essence of Christianity and brought it back to the issues of monotheism and a way of salvation.

Some believers and some scholars have always determined that the best way to preserve the essence of Christianity is to look at the earliest documents—the four Gospels and the letters that make up much of the New Testament—which tell whatever is believed to be known with any kind of assurance about what the earliest Christians remembered, taught, or believed about Jesus Christ. It is presumed that "the simple Jesus" and the "primitive faith" emerge from these documents as the core of the essence.

The New Testament as a source for the essence

Other believers and other scholars, however, have disturbed this simple notion of finding the essence by going back to the beginnings. The writings that make up the New Testament themselves reflect Jewish and Greek ways of thinking about Jesus and God. They are seen through the experience of different personalities, such as the Apostle Paul or the nameless composers of documents that came to be edited as the Gospels. Indeed, there are not only diverse ways of worship, of polity or governance of the Christian community, and of behaviour pictured or prescribed in the New Testament but also diverse theologies, or interpretations of the heart of the faith. Most believers see these diversities as complementing each other and leave to scholars the argument that the primal documents may compete with and contradict each other. Yet there is a core of ideas that all New Testament scholars and believers would agree are central to ancient Christian beliefs. One British scholar, James G. Dunn, for example, says they would all agree that "the Risen Jesus is the Ascended Lord." That is to say, there would have been no faith tradition and no scriptures had not the early believers thought that Jesus was "Risen," raised from the dead, and, as "Ascended," somehow above the ordinary plane of mortal and temporal experience. From that simple assertion early Christians could begin to complicate the search for essence.

An immediate question was how to combine the essential focus on Jesus with the essential monotheism. Some of the writers of the New Testament and more of the Apologists, late 1st- and 2nd-century reflectors on the meaning of this faith in both the Jewish and Greek contexts, saw Jesus as the "preexistent Logos." That is, before there was a historical Jesus born of Mary and accessible to the sight and touch of Jews and others in his own day, there was a Logos—a principle of reason, an element of ordering, a "word"—that participated in the Godhead and thus existed, but which only preexisted as far as the "incarnate" Logos, the word that took on flesh and humanity (John 1:1–14), was concerned.

Monotheism and the divinity of Jesus

In searching for an essence of truth and the way of salva-

tion, some primitive Jewish Christian groups, such as the Ebionites, and occasional theologians in later ages spoke in terms of what might be called a metaphor of adoption. These theologians used as their source certain biblical passages (*e.g.,* Acts 2:22). Much as an earthly parent might adopt a child, so the divine parent, the one Jesus called *abba,* "daddy" or father, had adopted him and taken him into the heart of the nature of what it is to be God. There were countless variations of themes such as the preexistent Logos or the concept of adoption, but they provide some sense of the ways the early Apologists carried out their task of contributing to the definition of the essence of their Jesus-focused yet monotheistic faith.

While it is easier to point to diversity than to simplicity or clarity among those who early expressed faith, it must also be said that from the beginning the believers insisted that they were—or were intended to be, or were commanded and were striving to be—united in their devotion to the essence of their faith tradition. There could not have been many final truths and there were not many legitimate ways of salvation. It was of the essence of their tradition to reject other gods and other ways, and most defining of essence and identity occurred as one set of Christians was concerned lest others might deviate from the essential faith and might, for example, be attracted to other gods or other ways.

While Jesus was among his disciples and those who ignored or rejected him, to make him the focus of faith or denial presented one type of issue. After the "Risen Jesus" had become the "Ascended Lord" and was no longer a visible physical presence, those at the head of the tradition had a different problem. Jesus remained, as was said, a present reality to them, and when they gathered to worship they believed that he was "in the midst of them." He was present in their minds and hearts, in the spoken word that testified to him, and also present in some form when they had their sacred meal and ingested bread and wine as his "body and blood." They created a reality around this experience; if once Judaism was that reality, now "Christianism," or Christianity, resulted.

The search for the essence of Christianity necessarily led people in the Greek world to concentrate on ideas. The focus on Jesus narrowed to ideas, to "beliefs about" and not only "belief in," and to doctrines. The essence began to be cognitive, referring to what was known, or substantive. This was most pronounced when people in the idea-centred Greek culture had to grasp through the mind the reality of someone who was not a visible presence.

As debates over the cognitive or substantive aspects of Jesus' participation in God became both intense and refined, the pursuit of essences became almost a matter of competition in the minds of the Apologists and the formulators of doctrines in the 3rd through the 6th centuries. During this time Christians met in council to develop statements of faith, confessions, and creeds. The claimed essence was used in conflict and rivalry with others. Christian Apologists began to speak, both to the Jews and to the other believers in the Greco-Roman world, in terms that unfavourably compared their religions to Christianity. The essence also came to be a definer of who had the best credentials and was most faithful. The claim that one had discerned the essence of Christianity could be used to rule out the faithless, the apostate, or the heretic. The believers in the essential truth and way of salvation saw themselves as insiders and others as outsiders. This concept became important—and, its victims would say, dangerous—after the Christian movement had triumphed in the Roman Empire, which became officially Christian. To fail to grasp or to misconceive what was believed to be the essence of faith might mean exile, harassment, or even death.

Confessions and creeds as the essence

In the move from their exclusive roots in Judaism to their experience in Greek and Roman cultures, Christians did something rare if not unique in the history of religion: they adopted the entire scriptural canon of what they now saw to be another faith, Judaism, and embraced the Hebrew Scriptures as what they called the Old Testament. But while doing so, they also incorporated the insistent monotheism of Judaism as part of the essence of their truth and way of salvation, just as they incorporated the Hebrew Scriptures' story as part of their own identity-giving narrative and experience.

This narrowing of focus on Jesus Christ as truth meant also a complementary sharpening of focus on the way of salvation. There is no purpose in saving someone who does not need salvation. Christianity therefore began to make, through its councils and creeds, theologians and scholars, some attempts at definitive descriptions of what it is to be human. Later some of these descriptions were called "original sin," the idea that, inherited from Adam, the first-created human, all mortals carried a condition that made it impossible for them to be perfect or to please a personal God on their own. While Christians never agreed on a specific teaching on original sin, they did describe as the essence of Christianity the fact that something limited humans and led them to need redemption. Yet the concentration always returned to Jesus Christ as belonging more to the essence of Christianity than did any statements about the human condition.

The essence of Christianity eventually included statements about the reality to God. Christians inherited from the Jews a relatively intimate picture of a God who made their young and small universe, with its starry heavens, and then carried on discourse with humans, making covenants with them and rewarding or punishing them. But the Greek part of their tradition contributed the concept of a God who was greater than any ideas of God but who had to be addressed through ideas. Indeed, it was during this time that words such as essence, substance, and being—terms that did not belong to the Old or New Testament traditions—came to be wedded to biblical witness in the creeds. Christians, it might be said, used the vocabulary and repertory of options then available to them in speaking of the all-encompassing and the ineffable and grafted these onto the witness to God that was essential to their faith. Modern Christians, including many who reject the notion of creeds or any non-biblical language, are still left with the problems and intentions of the ancients: how to think of Jesus in such a way that they are devoted to him not in isolation, as an end in himself—for that would be idolatry of a human—but in the context of the total divine reality.
